Mr. C. H. FAGGE showed a case of Myeloma of the Head of the Tibia Seven Years after Enucleation. The patient, a girl aged 11, first noticed a swelling over the head of the left tibia about January, 1905. The pain made her limp, and in April, 1905, the tibia was explored on the suspicion of abscess or myeloma; nothing abnormal was found even after free exposure and drilling of the bone. Pain continued in spite of iodides, and swelling increased, particularly on the lateral aspect of the bone. X rays showed the upper end of the tibia expanded, and the original diagnosis of myeloma was reverted to; there was no albumosuria. A year after the first operation the bone was again exposed, and in separating off the periosteum a large cavity in the bone filled with maroon-coloured growth was entered. The opening was enlarged by cutting away the compact layer with a gouge, when the upper third of the bone was found expanded and hollowed out. Posteriorly over a large area the exploring finger came in contact with bare periosteum. The soft growth was carefully scraped away with a Volkmann's spoon, and the cavity washed out with saline and packed with gauze. Microscopically the growth showed general myxomatous degeneration, but in one part were mingled round and spindle cells with several myeloid cells scattered among them.

Mr. FAGGE also showed a case of Re-formation of the Fibula after Complete Removal of the Diaphysis for Acute

Infective Periostitis A boy, aged 11, was admitted into Guy's Hospital in December, 1911 with an acute inflammatory swelling of the outer side of the right leg, the knee- and ankle joints were not involved Incision disclosed the shaft of the fibula lying bare in a large subperiosteal abscess, its lower limit was the lower epiphyseal line, and through this the bone was divided with a chisel, and the diaphysis separated by torsion, the cavity was packed A second abscess over the outer side of the knee was incised, pus from both cavities contained staphylococcus aureus Saline was infused subcutaneously into both axillæ, and two days later both areas of infusion become infected, and pneumonia developed at the right base Two pectoral abscesses were opened and antistaphylococcal serum was given Skiagrams taken at intervals since January, 1912 showed a gradually darkening shadow in the position of the fibula, which had become completely osseous except just below the upper epiphyseal line Section of the removed diaphysis showed a pyogenic focus in the medulla, from which a sinus led through the compact layer

Mr **LIONEL E C NORBURY** showed a case of Re formation of the Tibia after Resection of the Diaphysis for Chronic Osteomyelitis (? Syphilitic) The patient, a boy aged 10, was admitted to hospital on July 25th, 1912 There was a history of swelling of the left tibia for four years, and a previous history of eye trouble There had been an ulcer on the right leg two years before His father was said to have had a chancre, and his mother to have suffered from tuberculous ulcers of the leg and shoulder On examination [illegible] ving forward of the [illegible] the bone extended from just below the tibial tubercle to 2½ inches above the ankle joint Nodes were present on the tibia, one of which was tender A skiagram showed diffuse sclerosis of bone, with several light areas, suggesting collections of pus There was a small node on the right shin and a scar of an old ulcer on the right leg The diagnosis lay between syphilis and tuberculosis The Wassermann reaction was negative He was treated with mercury and potassium iodide and also with mercurial inunctions No local change occurred In August subperiosteal resection of five inches of the shaft of the tibia was done The periosteum was adherent to the bone in two places, and was button holed at these spots The openings were closed with catgut sutures The periosteal sleeve was closed with interrupted catgut sutures The wound healed by first intention A plaster of Paris splint was adjusted 24 days after the operation, and re applied several times since A skiagram showed a considerable degree of re formation of the shaft which however, was not yet complete The microscopical report on a decalcified section of the bone removed was "Chronic osteitis No evidence of tubercle Evidence of syphilis indefinite also, but there is one area showing a mild endarteritis"

Dr F **PARKES WEBER** showed a case of Ateleiosis in a [illegible] three years ago, and since then there had been little change

Dr **WEBER** also showed a case of Ateleiosis in a woman, aged 20 with a Slight Congenital Malformation of the Hands and Feet The patient, of Polish Jewish descent born in June, 1892, was small and infantile Height, 135 cm, weight 34 kilogrammes According to the mother's account she was born at full term without instrumental aid She learned to talk and walk like other children She was always small and delicate, but had hardly increased in height or general development since the age of 12 She had never menstruated She was the eldest child of healthy parents There seemed to have been no dwarfism infantilism, or congenital malformation of hands and feet in any other members of the patient's family When exhibited there was a slight congenital malformation of the hands and feet, consisting in decided relative shortness of the fourth finger of each hand and the fourth toe of each foot Roentgen ray examination of the hands and feet showed this deformity to be due to shortness of the metacarpal and metatarsal bones The lower jaw was relatively somewhat small and the chin receding The teeth were fairly well developed The thyroid gland seemed very small The breasts were quite infantile, and there was complete absence of pubic and axillary hair Although a small intravaginal portion of the cervix uteri was present, the body of the uterus seemed almost absent, and no ovaries could be felt. In proportion to the bodily growth the patient's mental development seemed to be fairly good, and she was able to earn a little money at machining In regard to the osseous system, there was slight spinal scoliosis Skiagrams showed abnormal persistence of epiphyseal cartilages In those taken of the hands most of the epiphyses were seen to be bordered by a very deep shadow as if by sclerosed bone. Skiagrams of the region of the sella turcica at the base of the skull seemed to show a rather small pituitary fossa with a long, thin posterior clinoid process stretched out in a forwards direction

Mr P **MAYNARD HEATH** showed a case of Pseudo hypertrophy of the Breast The patient was a girl aged 16 In March, 1912, she noticed that the right breast was growing bigger than the left It continued to grow until November, 1912, since when there had not been much increase At no time had there been any pain The breasts began to develop at the age of 14 Menstruation started at the age of 15 and had been slightly irregular, the intervals between the periods being sometimes five or six weeks It was stated that the breast got slightly larger just before the period and decreased after it The right breast was considerably larger than the left There were some superficial enlarged veins, but the skin was normal The whole breast tissue was lumpy and appeared to be divided up into more or less separate lobules. There was no tumour which could be separated from the breast tissue The breast was not adherent to the chest wall There were a few enlarged glands under cover of pectoralis major The left breast was slightly lumpy There were no glands in the left axilla The girl's general health was said to be indifferent and she had a cough, but there were no signs of pulmonary tuberculosis, from which disease her eldest sister, aged 21, suffered The breast had remained in the same condition for the last four months in spite of continuous support and pressure with Scott's dressing

Mr **HEATH** also showed a case of Congenital Cyst in the Parotid Region The patient was a girl, aged 16 A swelling in front of the right ear was noticed soon after birth When the patient's head was erect there was a distinct hollow in front of the tragus At the bottom of this hollow was a hard nodule about the size of a millet seed, which was tender on pressure The skin over the hollow was normal in appearance When the patient bent her head downwards and to the right the hollow gradually filled up and was replaced by a rounded swelling, which projected about half an inch above the surface of the cheek The skin over the swelling then showed a faint blue tinge The swelling was cystic and could be made to disappear by pressure It was not translucent, and no pulsation or impulse could be detected in it There was no abnormality in the auricle or meatus

Mr **LAWRIE H MCGAVIN** showed 1 A labourer, aged 32, who on June 5th 1912 fell a distance of 40 feet, and was admitted to Seamen's Hospital with simple fracture of both bones of the right leg On June 11th Mr McGavin operated and plated the fibula with a four screw plate On July 25th he was discharged apparently cured On August 23rd the plate was removed, and on Sept 24th he was discharged "relieved," but still with swelling of the right ankle On Feb 14th, 1913 he was readmitted with swelling of the left knee joint This swelling subsided under strapping with Scott's dressing but had reappeared each time that he had been allowed to use the joint for walking On Feb 18th the knee joint was washed out with 1 in 5000 perchloride solution There was still some swelling of and fluid in the joint, and much grating on passive movement and slight grating in the right knee joint also X rays showed no bony change 2 A man, aged 38 who had been admitted to the Seamen's Hospital on Nov 11th 1912, suffering from double hernia On Nov 14th Mr McGavin operated under stovaine anæsthesia Bassini's operation was done on both sides On Feb 21st he complained of pain in and swelling of the left calf, and the internal saphenous vein was felt to be thrombosed on the inner side of the left thigh 3 A man aged 63 There was a swelling in the left submaxillary region which appeared to be a mixed tumour of the left submaxillary salivary gland 4 A boy aged 16 A small abscess had been found in the substance of the psoas muscle No carious bone was discovered Cultivation yielded no organism of any kind. Mr. McGavin raised the question as to whether it was a case of non-tuberculous psoas abscess.

Mr. P. Lockhart Mummery read a short paper on a case of Ulcerative Colitis terminating fatally. The patient, a man aged 49, had diarrhœa and bleeding from the rectum for the last three years, but became worse during the last three months before his admission to the hospital. He also had vague abdominal pains, felt very weak and ill, and had lost weight to a considerable extent. The stools varied from eight to ten in 24 hours, and were usually blood-stained. He was admitted to St. Mark's Hospital on Jan. 25th this year. He then had a slight chronic cough, and on examination there were slight signs of tubercle of both apices. He had well-marked pyorrhœa alveolaris. He was very thin, tender over the colon, and was passing a considerable number of stools during the day containing much mucus and blood. A sigmoidoscope examination revealed extensive ulceration of the bowel as far up as could be seen. On Jan. 27th the abdomen was opened in the middle line and the colon thoroughly examined. It was found to be thickened, and numerous ulcers could be felt, but no other lesion. The appendix was brought out through a stab puncture in the right iliac fossa, and an appendicostomy opening established. From this time the bowel was washed out repeatedly with water and solutions of argyrol, 1 per cent. There was some improvement for a time, and the wounds healed by first intention. Soon, however, the skin round the appendicostomy opening became ulcerated, and a slow form of ulceration gradually progressed in this situation, and ate away a large portion of the skin, and exposed the muscles and fascia in the abdominal wall. Nothing that could be done would prevent this ulceration from spreading, and soon there was an ulcer as large as half-a-crown round the opening. The patient's condition varied a good deal during the subsequent weeks. At the beginning of March he was certainly picking up, putting on flesh, and improving generally; but on March 5th he complained of pain in the chest, and on examination there was dulness at the left base. His pulse became rapid, signs of bronchial pneumonia set in, and he died. At the post-mortem examination there were well-marked bronchial pneumonia at both bases and scattered areas of consolidation. The liver, spleen, and kidneys were normal. On opening the peritoneal cavity there were no signs of chronic peritonitis, no adhesions, no enlarged glands; the whole of the ileum was perfectly normal. Very extensive ulceration was found throughout the colon, much more marked in the lower half. Over large areas the mucous membrane was entirely destroyed down to the elastic coat, with only a few islands of mucous membrane which stood up like polypi. Other sections showed well-marked, irregular-shaped ulcers of the most characteristic variety. In many parts of the specimen the appearance at first sight was that of multiple polypi of the bowel. This was, however, an artificial effect produced by the complete erosion of the mucous membrane, leaving small islands of mucosa, usually of a circular shape, and standing up exactly like polypi from the surrounding ulcerated area. It was noticeable that towards the cæcal end of the colon there was marked evidence of healing of many of the ulcers, no doubt due to the fact that this part of the colon, owing to the appendicostomy opening, was enabled to be kept much cleaner than the remainder; in fact, the ascending colon and cæcum showed very little ulceration, although there were numerous scars of healed ulcers. The ulcerated condition in many parts of the colon was so extreme that it would appear to be impossible for the patient to have recovered. As regards the bacteriology of the condition, owing to the large number of organisms usually found in the stools of these cases it was seldom possible to ascertain with any certainty the particular micro-organism which produced the lesion. In this case, however, Mr. Mummery thought that one could be fairly certain of the particular offending micro-organism, although unable to ascertain this by the ordinary culture methods. The nurse who was looking after this patient contracted a bad whitlow of the finger, and was for some days threatened with septicæmia. She was found to be suffering from a pure infection of staphylococcus aureus, and it seemed to him that there was every reason to suppose that this was the micro-organism causing the ulceration in the colon of the patient. Examination of the fæces for tubercle bacilli failed to produce evidence of the ulceration being tuberculous. This case was of interest chiefly for two reasons It was one of the very few cases he had met with in which the patient had not recovered from ulcerative colitis after an appendicostomy. Had the operation been performed earlier he believed this patient would have recovered. As a rule such cases, even where there was very extensive ulceration, rapidly recovered when the bowel was kept washed out, and it was obvious that in this case there was a very marked tendency to healing, although the ulceration was too severe for it to be complete. The other reason why he had ventured to bring it forward was because the specimen in places so closely imitated one of multiple polypi of the colon, although its pathology was of quite a different nature. At first sight one might easily suppose that the specimen was one of multiple polypi unless one examined microscopic sections. The patient was never out of England, and the case was a typical instance of acute ulcerative colitis.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases.

A clinical meeting of this society was held on April 4th, Dr. G. P. Shuter, the President, being in the chair. The following cases were shown and discussed.

Dr. N. T. Whitehead (for Dr. E. Arthur Saunders): Osteo-arthritis in a girl aged 11 years. A slight injury to the left hip occurred last October. Limitation of movement gradually set in, and a recent investigation with X rays revealed lipping of the cartilage and the presence of osteophytes. No possible source of infection was found beyond the presence of two carious teeth.

Dr. Whitehead (for Dr. J. M. Bernstein): Stenosis of Pulmonary Artery. The patient, a man, complained of great shortness of breath associated with pain over the cardiac area, the latter only a recent symptom. There was some degree of cyanosis but no polycythæmia, as might have been expected. The heart was dilated, especially to the right of the sternum. There were no dilated veins in the neck, nor did the liver pulsate. A systolic thrill could be felt over the pulmonary valve; a systolic murmur was audible over the whole of the cardiac area, but more especially over the pulmonary valve.—Dr. Seymour Taylor referred to the difficulties of diagnosis in cases of congenital heart defects. He would have expected in this case to have found evidence of the relief of the tension in the right ventricle along the line of least resistance—viz., through the tricuspid orifice—but he did not find any signs of this. He thought it possible the patient had aortic obstruction.

Mr. Donald J. Armour: A small boy who had received an unusual Injury to his Ulnar Nerve. About six or eight months ago he drove a splinter of glass into the palm of his hand. From the muscular wasting and paralysis it was clear that the deep branch of the ulnar nerve had been cut across just where it passed through the muscles of the hypothenar eminence in company with the deep branch of the ulnar artery. The superficial branch of the ulnar nerve had escaped, as shown by the fact that the inner side of the little and the adjacent side of the little and ring fingers were normal as regarded sensation. The muscles supplied by the deep branch of the ulnar—namely, the small muscles of the little finger, the inner two lumbricales, the interossei and the two adductors of the thumb—were completely wasted. As suture was out of the question Mr. Armour suggested excising the scar, in which no doubt the proximal end of the nerve was embedded, in order to give the nerve a better chance of regenerating.—Mr. H. Tyrrell Gray mentioned a method, adopted in America, of scoring with a small tenotome the scar tissue in lines parallel with the nerve fibres with the object of opening up fresh paths for the regeneration of the divided fibres.—Mr. Armour did not think it applicable to this case.

Mr. Sydney G. MacDonald: Perineal Testicle in a man aged 28. The testicle was small and the scrotum on the same side imperfectly developed. The patient himself was well developed, cycled constantly, and suffered none of the usual inconveniences. With regard to treatment it was not proposed to interfere at present, but if any operation became necessary excision was preferable to replacement in the scrotum of a functionless organ. Testicular neoplasms were more common in imperfectly descended than in normally situated organs, probably because they were imperfectly developed.

Dr. T. C. STOREY (for Dr. H. J. DAVIS): 1. Epithelioma of Auricle in a man aged 72. The growth commenced as a small lump on the outer border of the pinna, and finally broke and formed an ulcer. The auricle was removed, and the considerable raw area resulting skinned over with remarkable rapidity. The rarity of the condition was poin[illegible] ? [illegible] for Epithelioma of Larynx. The [illegible] suffe[illegible] The growth involved the left aryteno-epiglottidean fold, obscuring the view of the left cord. There was no apparent involvement of the tongue or epiglottis, but there was an enlarged gland in front of the left sterno-mastoid. A low tracheotomy having been performed, the growth was removed after dividing the thyroid cartilage in the middle line. The cartilage was then allowed to fall in place and was not sutured. On the sixth day the patient was allowed up and about the ward as a precaution against broncho-pneumonia, the most frequent cause of death after this operation. It was proposed to deal with the glands in a week's time unless signs of recurrence took place.

Mr. OSWALD L. ADDISON: 1. Genu Valgum and Dislocation of Patella in a stout middle-aged woman under treatment for osteo-arthritis, both legs being affected. The left patella lay on the front of the external condyle of the femur, the normal patellar surface of the femur being uncovered; on the right side the displacement was less extreme The patient was unaware of the deformity, which had given rise to no trouble until the last few months, when she began to have severe pain in the left knee. 2. Sporotrichosis in a boy aged 11 years. About the ankle on both sides of the tendo Achillis and spreading for some distance up the leg were numerous spongy-looking granulomatous masses which exuded a small amount of pus, and several sinuses were also present in the neighbourhood. On the back of the calf was a thin, broad, slightly pigmented scar, the result of an old operation, and similar scars were present on the front of the thigh and groin. Just above the knee there were two or three indolent cutaneous swellings which were gradually becoming softer. The movements of the ankle-joint were free, and in spite of the large amount of scarring of the leg the calf muscles were very little if at all contracted. The condition had followed an injury to the right ankle. A painless swelling developed, broke down in about six weeks, and continued to discharge for nearly a year before the patient presented himself at hospital. At this time the condition was thought to be tuberculous, but in spite of treatment gradually spread upwards. The patient's health was unaffected, the condition quite painless, and with the exception of the primary seat of infection and an enlargement of the femoral glands ending in their removal, the disease did not spread beyond the skin and subcutaneous tissues. Numerous pathological investigations had been made, until quite recently Dr. D. N. Nabarro found some mycelial threads and clusters of spores in a film preparation from a scraping, and came to the conclusion that the boy was suffering from one of the varieties of sporotrichosis. Cultural experiments had so far failed, and in order to be successful it was apparently necessary to obtain some pus from an unbroken abscess; this at present had not been possible. Mr. Addison referred to a full account of sporotrichosis by Professor de Beurmann,[1] and also mentioned that two cases of the disease affecting the skin had been published in this country by Dr. Norman H. Walker[2] and by Dr. H. G. Adamson.[3]—In reply to the PRESIDENT, Mr. Addison said the disease in this case had apparently spread by the subcutaneous tissues, but Dr. Beurmann described a form which chiefly affected the lymphatics and glands. The gummata softened and completely liquefied before the skin gave way, so as to lead to infection by secondary organisms. It was from one of these unbroken lesions that it was necessary to obtain pus in order to make satisfactory cultures.—Mr. T. JEFFERSON FAULDER referred those interested to a paper by Professor Ravogli, of Cincinnati, Ohio, read at the International Congress on Tuberculosis at Rome in 1912. The paper contained a very full account of the disease with a number of cases.

Mr. N. BISHOP HARMAN: 1. Exenteration of the Orbit and Partial Excision of Maxilla and Ethmoid for Rodent Ulcer. The patient, a woman aged 54, first noticed a small pimple on the right cheek just under the eyelid 17 years ago. It scabbed, and she treated it herself with various caustics whenever the lump reappeared. From 1905 X rays, zinc ions, and radium each appeared to benefit her for a time. When seen by him in 1911 with a view to operation she had lost the whole of the lower lid, and a rodent ulcer as big as a penny was fixed to the maxilla. An operation for removal of the growth was performed, and all seemed well until September, 1912, when there was recurrence in the orbit. A second extensive operation had then to be undertaken, with the result that the orbit, nose, and antrum were opened into one. The great cavity left gradually sank in a remarkable way, leaving the passage of the nose exposed to view in a striking manner. There had been no lack of treatment, but an earlier appeal to surgery would have left the patient with a sound face and two good eyes. 2. Excision of Lacrymal Sac in a young woman aged 19. Carious teeth had caused periostitis of the maxilla and consequent blockage of the lacrymal duct. When first seen she had had severe dacryocystitis for nine months. The sac was incised, scraped out, and drained. Eventually the whole lacrymal sac had to be removed, the bony duct scraped out, and the puncta destroyed in the manner described in a paper that appeared in the *West London Medical Journal*. The result was excellent. 3. A similar case in a young woman aged 20. There had been a septic mucocele for a month or two.—Mr. FAULDER congratulated Mr. Harman on the result of the operation in the first case, but pointed out that, as the sections of the growth contained cell nests and generally showed evidence of malignancy, it confirmed the well-recognised phenomenon of the transformation of rodent ulcer into epithelioma. He asked whether Mr. Harman had had any experience of an operation whereby the nasal duct was laid open within the nose by an intranasal incision and drainage established that way.—Mr. HARMAN replied that the cases that came before the ophthalmic surgeon were nearly always caused by blockage of the duct high up close to the sac. In these cases operation for exposure of the duct through the nose would not be effective, but the operation suggested seemed to be the right procedure when it was definitely ascertained the block was near the orifice of the duct.

UNITED SERVICES MEDICAL SOCIETY.

Duties of R.A.M.C. Officer with Infantry Battalion on Active Service.

A MEETING of this society was held at the Royal Army Medical College on April 9th, Fleet-Surgeon P. W. BASSETT-SMITH, C.B., R.N., the President, being in the chair.

Major HOWARD ENSOR, D.S.O., R.A.M.C., read a paper on the Duties of an Officer of the Royal Army Medical Corps attached to an Infantry Battalion on Active Service against a Civilised Enemy. After considering the duties of a medical officer with a battalion during mobilisation, Major Ensor dealt thoroughly with the important questions arising as to work on the line of march and in camp. Referring to the duties in a standing camp, he insisted that a camp should be regarded as "standing" when the troops have been in occupation of it for 24 hours and no orders have been issued for them to move. After the expiration of this time, in the absence of orders for the battalion to move on, the site of the camp should be regarded as an area likely to be occupied by the unit for some considerable time, and the necessarily primitive system of sanitation prevailing when a battalion is bivouacking for the night only should be changed for the more elaborate one suitable for a standing camp. This will prevent the serious error of postponing the institution of sound sanitary measures in the expectation that orders may arrive for the troops to move almost immediately, a mistake that frequently leads to the men remaining under undesirable conditions for several days. The sanitary condition of a camp is, perhaps, the best crit[illegible] of discipline of the troops occupying it. A matter of great importance is the cleansing of bivouac areas before starting on the march next day, as the same area is likely to be occupied by other troops at an early date. While advocating the early transfer of the febrile cases to the field ambulance when the troops are on the march, Major Ensor is in favour of retaining men suffering from a moderate degree of fever with their unit, when in standing camp, for 48 hours, isolating them as far as possible in tents or shelters until it is clear that they are not likely to prove able to continue at work. It should be remembered that cases sent to the ambulance tend to be evacuated to the lines of communication and lost to their battalion. That portion of the paper dealing with the duties of the medical officer and the regimental medical establishment in action was of such importance that a summary cannot serve to do more than invite attention to the paper itself, on its publication in full, but it may be said that the lecturer recommends a very thorough training of the regimental bearers in the application of the first field dressing and is inclined to advocate their employment for this purpose and the protection of casualties by the erection of temporary cover, rather than for the carrying of wounded to the aid-posts, during an action. He even suggests that the battalion stretchers instead of being carried behind the companies by the bearers at the beginning of an action, should be carried on a cart under the care of one of the Royal Army Medical Corps detachment, and only brought into use when darkness or a lull in the fighting permits the safe clearing of the wounded from the area of operations. The important question of the best position for the medical officer to take up in action, whether in the firing line or at some point farther back, was also fully considered both by the lecturer and those who spoke after him.

---

[1] [illegible] 1912.

[3] Proceedings of [illegible] See also THE LANCET, March 11th, 1911, p. [illegible]

The following officers took part in the discussion: Surgeon-General W. H. MACNAMARA, C.B., A.M.S., Colonel BRUCE M. SKINNER, M.V.O., A.M.S., Colonel J. HARPER, A.M.S. (T.), Colonel J. M. CADELL, I.M.S., Lieutenant-Colonel Russell, Lieutenant-Colonel C. H. BURTCHAELL, R.A.M.C., and Major E. B. WAGGETT, R.A.M.C. (T.).

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

Headache.

A MEETING of this society was held on March 19th, Mr. W. G. LAWS, the President, being in the chair.

Mr. H. HERBERT opened a discussion on Headache from an Ocular and Nasal Point of View. He mentioned that the patients generally referred their headaches to their eyes, and complained of aching and redness of the eyes after work or headaches after witnessing cricket matches or attending theatres. These headaches were generally fairly regular and continuous, and not capricious. Among the causes might be mentioned ciliary spasms in hypermetropia, differences between the refraction of the two eyes, and a tendency to squint. He regretted that often these headaches were not cured after taking advice because patients sometimes omitted to wear glasses. In other cases where manifest defects had been corrected other defects became manifest later, and, again, when patients were neurasthenic, they got into the habit of having headaches, and sometimes not sufficient time was given to examination of the eyes.

Mr. H. B. TAWSE continued the discussion from a nasal point of view. Briefly reviewing the anatomy of the nasal cavities, he described first the pain which accompanied acute disease in various parts of the nose. These headaches varied in intensity and character according to the position of the disease, and were due chiefly to the pressure of pus or of hypertrophied tissue. In children adenoids frequently caused headache owing to the deficient oxygenation of the blood. Nasal polypi caused headache, but this was not constant. The nose should be thoroughly examined in all cases of persistent headache.

Local and Spinal Anæsthesia.

A MEETING was held on April 2nd, Mr. LAWS, the President, being in the chair.

Mr. R. G. HOGARTH, in opening a discussion on Local and Spinal Anæsthesia, described the method of action of a solution of novocaine. It was not necessary that the solution should be injected into the nerve itself, but it was injected into the surrounding perineural tissue. This produced complete anæsthesia in the area supplied by the corresponding sensory nerves. When operating on small areas, it was sufficient to infiltrate the surrounding tissue for about two inches round the intended incision, with a 1 per cent. solution of novocaine. In operating on such areas as the scalp or fingers, it was sufficient to infiltrate at right angles to the sensory nerves supplying this area. For instance, the hand could be anæsthetised by infiltrating the median, ulnar, and radial nerves. Brachial plexus anæsthesia could be produced by injecting 60 c.c. of a 2 per cent. solution of novocaine into the brachial plexus as it passed over the first rib. The guide for this was the outer side of the subclavian artery just above the clavicle. Injections necessary to produce anæsthesia in various parts of the body were then described in detail. In particular, it was shown how the three divisions of the fifth nerve could be anæsthetised as they passed out of the base of the brain. For goitre operations it was necessary to infiltrate underneath as well as all round the tumour. Empyemata could readily be opened by blocking the three intercostal nerves concerned.

Mr. C. H. ALLEN reviewed the history of spinal anæsthesia. He employed Barker's solution of stovaine. The canal was punctured between the second and third lumbar interspaces. The patient should sit on the table with the legs hanging over and the back bent, or should lie doubled up with the pelvis and shoulders raised so that the mid-dorsal is the lowest dependent part of the canal. The puncture should be in the middle line, 5 c.c. of fluid allowed to escape, and then a syringeful of the solution injected. Anæsthesia was produced within 10 minutes and lasted for about an hour. No very serious sequelæ had been recorded in this country. Headache and pyrexia very often followed, but the headache was generally relieved by phenacetin. The chief advantages of this method of anæsthesia were absence of post-operative shock, complete muscular relaxation, no venous engorgements or respiratory movements, no starvation, and no post-operative sickness. As a disadvantage was urged the uncertainty of the anæsthesia. This method was contraindicated in cases of advanced sepsis. The special danger of septic meningitis was due to want of care and cleanliness in injecting the fluid. This method had been employed over 200 times at the General Hospital without any fatality, and in very few cases was the anæsthesia imperfect.

LIVERPOOL MEDICAL INSTITUTION.

Acute Pancreatitis.—Exhibition of Cases and Specimens.

A MEETING of this society was held on April 3rd, Mr. R. W. MURRAY being in the chair.

Mr. ARTHUR J. EVANS read a paper on Acute Pancreatitis. During the past 18 months he had operated on three cases. The disease was difficult to recognise and was often missed in the post-mortem room. His first case was a dock labourer, 35 years of age, who had been drinking heavily for ten days and vomiting incessantly for 16 hours. He had intense paroxysmal epigastric pain, the abdomen was retracted and fixed, especially in the upper part; he was delirious, with a rapid, thready pulse and subnormal temperature. On opening the abdomen the under surface of the omentum was studded with white areas; the pancreas was a large mass of necrotic tissue. The patient died in six hours. At the post-mortem examination no calculi were found. The second case was a woman, 51 years of age, fat, and of alcoholic habits, with a history of bilious attacks. She had been vomiting for several days, and had pain in the upper part of the abdomen. There was no jaundice, no abdominal distension, but fixation of the upper part of the recti. On opening the abdomen there were white, glistening plaques of fat necrosis on the omentum. The gall-bladder contained thick viscid bile and small calculi. This patient recovered. The third patient, a healthy man of 52, with no biliary history, was suddenly seized with severe epigastric pain and frequent vomiting. He had obstinate constipation followed by diarrhœa with green offensive stools; there was sugar in his urine. A month after this attack he was again seized with a similar attack. When the abdomen was opened there were extensive adhesions and the peritoneum was red, but no fat necrosis was seen. An irregular mass was found behind the stomach. This was *drained. The gall-bladder and duodenum were apparently* normal. There was marked improvement after the operation, and the sugar disappeared from the urine; on the seventh day after the operation he became delirious and died three days later. No examination could be made. Mr. Evans pointed out the common association with gall-stones, [illegible] he thought the agonising pain in [illegible] ing and collapse, tenderness and [illegible] the abdomen were the important signs. Cases were often mistaken for intestinal obstruction. Drainage of the abdominal cavity and if necessary of the gall-bladder seemed the only treatment available.—Mr. F. T. PAUL thought the intense pain in these cases was typical peritoneal pain not due to the gland. He alluded to pancreatic cysts which, he said, varied much in their results, some being easy to deal with, others discharging a secretion which was very injurious to the tissues. He had seen many obstructed bile ducts that did not cause acute pancreatitis and he thought the causation of the condition was not clear. —Mr. R. W. MURRAY thought the acute pain was due to the irritation of the parietal peritoneum. It was not clear how the panc [illegible] of the duct by [illegible] He had seen a c [illegible] ddenly after an operation on the knee-joint and the patient died. —Dr. A. STOOKES had seen a case in a woman sent into the maternity hospital for intestinal obstruction at full time; in that case Cæsarean section was done. The child was dead, the whole of the small intestine from the jejunum to within three inches of the ileo-cæcal valve was empty and collapsed. The peritoneal surface was everywhere red, *the colour of tinned salmon, and studded with fine yellow* spots; the large intestine contained gas but was not overdistended; the small intestine, 4 inches from the caput cæcum, formed a loop with which the caput cæcum and the vermiform appendix hung down into the pelvis behind the uterus, the mesocolon being there about 6 inches long. No mass was noticed in the upper part of the abdomen. Was it possible that obstruction due to the long mesocolon had caused pancreatic trouble with the fat necrosis of the peritoneum? There had been vomiting and probably reversed peristalsis for several days.—Mr. EVANS, in reply, said that he thought the acute pain and the extreme constipation might be due to the effect of the pancreatitis on the solar plexus.

The following cases and specimens were shown:—

Dr. A. GORDON GULLAN: Myxœdema, woman, aged 55; Pernicious Anæmia, male, aged 49; Pernicious Anæmia (?), *male, aged 55.*

Dr. JOHN HAY: Myasthenia Gravis in a woman; Acute Anterior Poliomyelitis in a man.

Mr. D. DOUGLAS-CRAWFORD and Dr. JOHN OWEN: Patient four years after removal of Tumour of the Spinal Cord.

Mr. R. C. DUN: Congenital Deformity of Ear; Spina Bifida Occulta; Cystic Goitre; Tumour of Foot (Exostosis)

Mr. G. C. E. SIMPSON: Early Keloid; Hypertrophied Scar; Congenital Scoliosis; Child after Congenital Exophthalmos; case of Sarcoma of Thyroid, operation and X ray treatment.

Dr. LESLIE ROBERTS: Disseminated Lupus; Multiple Rodent Ulcer; [illegible] Spreading Lup [illegible]

Dr. G. S. STO [illegible] RICHARD STOFFORD-TAYLOR: Lupus Pernio; Scrofulodermia; *Lupus Erythematosus affecting the scalp; Lupus Erythematosus*; Congenital Syphilis; Syphilitic Leucodermia; Hydroa Æstivale; Darier's Disease, showing the result of treatment with X rays; Ichthyosis.

Dr. FRANK H. BARENDT: Varicella prurigo; Tuberculide vel Syphilide; Tuberculide; Calvities post X rays; Perniones (tubercular).

Mr. T. H. BICKERTON: Cases of Chronic Glaucoma treated by "Elliot's operation."

Mr. HUGH E JONES: Persistent Hyaloid Artery; Epithelioma of External Auditory Meatus.

[illegible] RKE: Lupus [illegible] the Palate [illegible] and instru- [illegible] for Chronic *Suppurative Otitis Media.*

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

Exhibition of Patients.—Subglottic Tumour.—Intratracheal Insufflation of Ether.

A MEETING of this section was held on March 28th, Dr. R. D. PUREFOY, the President, being in the chair.

Mr. ROBERT H. WOODS showed a case of Acute Labyrinthitis in a man who was admitted to hospital with pain in the left ear, vertigo, and deafness. He had no fever while in hospital. Two days after admission a sero-purulent discharge appeared in the left external meatus and lasted for two days He said that six years ago he had had a similar attack on the right side, from which he recovered, with complete loss of hearing on that side. There was slight fulness under the sternomastoid on the left side. The membrane was slightly inflamed. No pus was recognisable. He was so deaf that he was unable to hear questions even when shouted into his left ear. The deafness on the right side was absolute. There was slight spontaneous nystagmus and nystagmus after turning of small amplitude, lasting 15 seconds, both to the left and right side. The tuning fork just recognisable on the left mastoid; Schwabach's sign greatly shortened; the teeth slightly jagged at the edges, the central upper incisors slightly notched. Wassermann reaction doubtfully positive. The following day salvarsan was given intravenously, and mercury and iodide of potassium prescribed. Hearing is gradually returning in the left ear. He can now hear conversations three feet away on the left side, but the deafness on the right remains absolute.

Mr. W. I. DE C. WHEELER showed a patient with a Central Dislocation of the Hip. The interest of the case lay in the rarity of the condition and the good functional result obtained by leaving the dislocation unreduced.

Mr. WOODS read a paper on Two Cases of Subglottic Tumour. The first case was that of a boy, aged 11 years, with increasing difficulty of breathing. Stridor was very audible and the suprasternal notch sank during inspiration. Bronchoscopy under general anæsthesia showed a fungating granulomatous tumour growing from the right wall of the trachea immediately above the bifurcation. The growth was removed by forceps Bronchoscopy was repeated under local anæsthesia and the tumour gradually entirely removed. *A skiagram showed thickening of the glands at the bifurcation* of the trachea. Six months later there was no trace of the tumour, and the opacity to X rays had completely cleared up. The growth was "round-celled with many blood-vessels, apparently granulation tissue." The second case was that of a man, aged 40, who for some years suffered from difficulty in breathing. The laryngoscope showed a tumour below the vocal cords apparently filling the whole trachea. The movement of the cords was free and the voice unimpaired. The bronchoscope showed the growth to be fixed by a broad base to the anterior part of the larynx or trachea below and clear of the vocal cords. A piece removed for examination was reported by Professor O'Sullivan to be malignant. The growth was removed by [illegible] It was found to grow from the cricoid [illegible] an uninterrupted recovery, but [illegible] *oid fever, from which he died* three months later. The trachea was obtained, and the site of the growth found to be perfectly healed.

Dr. H. DE L. CRAWFORD read a paper on the Intratracheal Insufflation of Ether, and demonstrated his apparatus. This method was first introduced in 1909 for experimental work, and ever since then had been used with marked success on human beings. It consisted essentially in forcing etherised, warmed, and filtered air into the trachea at a point one inch above the bifurcation through a catheter which was passed through the larynx from the mouth The air then returned between the catheter and laryngeal wall. The chief advantages were that it permitted full oxygenation of the blood even if both pleuræ were opened, that no blood, vomit, or mucus could get down through the glottis, and that the anæsthetist was *quite out of the surgeon's way.* In operations on the head and neck. He had found the method quite free from danger and very satisfactory, but emphasised the necessity for using an automatic safety valve of mercury. —Sir JOHN LENTAIGNE said that he had often felt the need for some means of producing positive pressure to do away with collapse of the lungs in operations on the chest wall, and the instrument shown would appear to do this. Unquestionably, in any case in which the chest wall had to be interfered with to any extent the apparatus must add enormously to the safety of the patient.—Dr. T. P. C. KIRKPATRICK said that theoretically the method seemed to be one which would overcome some of the most serious difficulties that anæsthetists had to deal with. He pointed out that the apparatus would be chiefly used for operations on the thorax, but thought there was a considerable field of usefulness for it in upper air-passage cases.—Mr. A. A. MCCONNELL pointed out that the expense of negative pressure cabinets had hitherto almost prohibited their use. He detailed the variety of cases in which the instrument had been used with the greatest success, and noted that Frazer, of Philadelphia, used the instrument in all his head cases. It was not necessary to have the patient deeply anæsthetised when introducing the tube.

ULSTER MEDICAL SOCIETY.—The first pathological meeting of the session of this society was held in the Pathological Laboratory of the Queen's University on April 3rd, Dr. R. W. Leslie, the President, being in the chair.—Professor W. St. C. Symmers and Dr. W. W. D. Thomson showed specimens illustrating Streptotrichal Infection of the Scrotum of a pony, and a series of Pathological Specimens from cases in which sudden death had occurred (ruptured thoracic aneurysm, hæmorrhage into the pons, hæmorrhage into the ventricles, and broncho-pneumonia after measles causing sudden death in a tram-car).—Dr. C. Kevin and Dr. Thomson showed slides from a case of Splenomedullary Leucocythæmia showing improvement under arsenic.—Dr. J. E. MacIlwaine gave a fully illustrated demonstration of Pipette Analysis for the examination of small quantities of blood, urine, &c.—Dr. W. J. Wilson showed a new Vaccine Container, and illustrated methods for administering vaccines by weight rather than by number.—Sir John Byers and Dr. Thomas Houston communicated a paper on a very rare case of Tetragenus Septicæmia, fully illustrated with cultures, slides, thermometric charts, &c., in which vaccines had been successfully used in the treatment of the general condition, as well as the local lesion in the ear.—An interesting discussion followed.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—A quarterly court of the directors of the above society was held on Wednesday, April 9th, Sir Thomas Boor Crosby, president, in the chair. Fifteen directors were present. Four gentlemen were elected members of the society. Since the last court one of the widows in receipt of grants had died. She had been on the funds since 1872, and had received from the society the sum of £2500. Her husband had paid in subscriptions 50 guineas. The acting treasurer, Dr. F. de Havilland Hall, reported that the society would shortly benefit to a very large extent under the will of the late Mr. James Brickwell. Mr. Brickwell was elected a member in 1833, and died in 1893, and by his will made the society his residuary legatee, his son, however, having a life interest in the money. The total amount of the legacy cannot at present be definitely fixed, but will probably exceed £36,000. Dr. de Havilland Hall hoped to be able to make a definite statement at the July court. The invested funds of the society now amount to £101,600. The annual general meeting was fixed for Tuesday, May 6th, at 5 P.M.; notices will be posted to the members in due course. Membership is open to any registered medical practitioner who at the time of his election is resident within a 20 mile radius of Charing Cross. The annual subscription is 2 guineas. Special terms for life membership, which vary with the age of the candidate. Application forms for membership and further particulars may be obtained from the secretary at the offices of the society, 11, Chandos-street, Cavendish-square, W.

Reviews and Notices of Books.

Diseases of Women. By THOMAS GEORGE STEVENS, M.D., B.S. Lond., F.R.C.S. Eng., M.R.C.P. Lond., Obstetric Surgeon, with Charge of Out-patients, St. Mary's Hospital, Paddington; Surgeon (Gynæcological), the Hospital for Women, Soho-square; Physician to In-patients, Queen Charlotte's Lying-in Hospital; Examiner to the Central Midwives Board. With 202 illustrations. London: University of London Press (Henry Frowde). 1912. Pp. 431. Price 15*s.* net.

IN his preface to this work the author puts forward the view, most certainly a correct one, that the study of gynæcology must be carried out upon a pathological basis in the same way as medicine and surgery. The importance of this to anyone who has had much experience in teaching this subject is obvious, and yet, curiously enough, there seems to be rooted in the mind of the student an idea that in some mysterious way the pathology of the female pelvic organs differs from that of the body as a whole, and requires separate consideration and study. No doubt this is a survival of the old ideas which for so many years held the field, and which, even in some modern text-books, have not been entirely banished, that the etiology and pathology of the diseases of the uterus and its appendages have a character of their own and are not to be explained by the principles of general pathology.

Dr. Stevens's reputation as an authority upon pathological anatomy lends additional weight to his views and value to this book. The work is, above all, distinguished by the very clear and full descriptions given of the pathology of the various affections, while the large amount of experience upon which the conclusions are based entitles them to our most careful consideration. It is interesting to turn to the description of so-called endometritis and to read the author's views upon the exact nature of the different conditions grouped under this heading. We are glad to see that Dr. Stevens condemns the term "diffuse benign adenoma" for cases of thickening of the endometrium in which no acute infection has been known to occur. He also rejects the view that such thickening may be due to the persistence of changes which accompany the menstrual cycle. He points out that inflammation in any part of the body essentially consists of two manifestations—namely, leucocytic infiltration and overgrowth of the fixed tissues of the part. Undoubtedly in cases of true endometritis we see the two processes, leucocytic infiltration and overgrowth, both present, and in cases of so-called adenoma we also see exactly the same overgrowth of glands and connective tissue without any leucocytic infiltration. In the author's opinion, therefore, it is perfectly legitimate to regard the endometrial thickenings as the overgrowth moiety of a very chronic inflammatory process due to a past infection from which both the organism and the leucocytic infiltration have disappeared. The suggestion is also put forward that some of these thickenings are toxic in origin and analogous to some cases of chronic mastitis. The author, in our opinion, is inclined to disregard to too great an extent the effect of chronic pelvic congestion, which undoubtedly is very often present, more particularly at the present day, when the prevention of pregnancy is so common a custom. Dr. Stevens would not deny that long-continued or often-repeated congestion of a part will lead to overgrowth just as well as chronic infection, and for this reason we still think that a large number of cases of so-called endometritis are in reality the result of pelvic congestion and not necessarily the sequelæ of infection; and it must be remembered that in many of these no evidence of any infection can be obtained, and often there is nothing in the history of the patient to suggest any such thing

We notice that Dr Stevens favours Gilliam's operation for cases of backward displacement requiring operation performed according to Mayo's method In discussing the treatment of cases of dysmenorrhœa he condemns dilatation of the cervix to an unwarranted degree perhaps when he says that this procedure rarely cures We should not have thought that this was the experience of most gynæcologists; it certainly often fails because it is carried out in cases which are not suited for it and are not in reality cases of true spasmodic dysmenorrhœa The operation is recommended by Dr Stevens to be combined with curettage, and in young sterile women with splitting of the posterior lip of the cervix The chapter on displacement of the pelvic organs is particularly good and the author's recommendations as to treatment are sound Possibly he gives too great a prominence to the part played by the levator ani muscle and too little to the so called endopelvic fascia or the suspensory fascia of the uterus described by Waldeyer A study of the plates in "Liepmann's Atlas of the Anatomy of the Pelvis" shows very admirably how important a structure this fascia is and how a complete prolapse can occur with very little alteration in the levator ani muscle

The whole book is a refreshingly good one; there is no chapter in it that the student or practitioner can read without profit, and, as we have said, it is particularly strong in its pathology The illustrations are good, and the plan Dr Stevens has adopted of reproducing his large micro photographs by direct photography upon a plate exposed in the rays of the epidiascope is certainly a success

Salvarsan in Syphilis and Allied Disorders By J E R MCDONAGH, F R C S Eng, Surgeon to Out patients, London Lock Hospitals London Oxford University Press (Henry Frowde and Hodder and Stoughton) 1912 Pp 164 Price 7*s* 6*d* net

Ueber die Pathogenese der Salvarsantodesfalle Von Dr WILHELM WECHSELMANN, dirigierendem Arzt der dermatologischen Abteilung im Rudolf Virchow-Krankenhaus in Berlin Mit 7 Textabbildungen Berlin und Wien Urban und Schwarzenberg 1913 Pp 84 Price 4 marks

THE continuous outflow of works from the medical press of all countries connected with the subject of syphilis and salvarsan affords a good proof that the medical profession has studied this synthetic remedy thoroughly and that its value is being recognised to the full At the same time the difficulties both of its administration and of the choice of suitable cases are being acknowledged, and inquiries are proceeding to eliminate so far as possible the objections that have been raised against this therapeutic weapon The works the names of which are quoted above all deal in one way or another with salvarsan

In Professor Ehrlich's work are collected a very large number of papers on salvarsan taken from the periodical literature and dealing with the various aspects of the subject They relate to the manner of injection, to the influence of the drug on the nervous system, to its use in visceral syphilis, to by effects of salvarsan, and to the relation of fatal cases and their explanation Some articles relate to the value of the drug in framboesia, in malaria, in scurvy, and in various other diseases Thus it is seen that the book is a storehouse of information on various points in the use of salvarsan, and as such it will prove of value to all who are investigating the use of the drug, but it will be of little value to the general practitioner

Dr. Leredde, in his little treatise, has dealt with many important points in connexion with syphilis He explains clearly the Wassermann reaction, and he shows what the results of an injection of salvarsan are He describes the various methods of introducing salvarsan into the body, and he discusses the causes of unfavourable results He considers that every case should be treated individually and that treatment should be continued until a negative Wassermann reaction is permanently obtained This result, he says, may be attained either by salvarsan or by mercury, and it will follow a four years' course of the injection of "grey oil" On the whole, he is opposed to the simultaneous administration of mercury and salvarsan, as he considers that it will tend to induce surgeons to give doses which are so small as to be ineffective He thinks that it is better, if mercury is used at all, to employ the full treatment and then to give salvarsan if any manifestations of the disease remain, or if salvarsan treatment is ineffectual, then it is justifiable in his opinion to administer a course of mercury

Mr McDonagh's work is *eminently practical, it deals* with the administration of the drug and its value in the treatment of syphilis, and it demonstrates that in suitable *cases the results obtained are excellent The author shows what influence salvarsan has on the Wassermann reaction* and also discusses its employment in diseases other than syphilis

Dr Wechselmann has done much for the spread of the employment of salvarsan, and he has added to the debt which the medical profession owe him by the publication of this timely work on the causes of death in those patients who have died after the administration of salvarsan He points out that the cases requiring investigation are not those in which patients with severe organic disease die after an intramuscular injection of salvarsan, but those in which healthy young persons die within a short time of an intravenous injection with acute symptoms, and when no gross technical error in administration has been committed From the fact that several patients have been injected from the same solution of salvarsan and yet only one of the number has died, it is clear that the cause of the death must be sought in some peculiarity in the patient himself and not be attributed merely to the drug The author discusses the various cases and classifies them so far as is possible, and he comes to the conclusion that in most fatal cases the result could be *directly attributed to the salvarsan in only a very small pro*portion though it may have had some influence in many He thinks that a very large number of the deaths could have been avoided if more care had been taken in the administration of the drug He advises that the greatest care should be taken in the technique; that the dose should be carefully adjusted to the case, that the condition of the kidneys should always be investigated, for any deficiency in the action of these organs increases the danger, that *mercury* and salvarsan should never be administered simultaneously, but that if the combined treatment is desired the salvarsan should be given first and then after an interval the mercury may be cautiously employed, and lastly, that all abnormal symptoms and any rise of temperature after an injection of salvarsan should be carefully investigated in order that the cause may be found and remedied if possible

---

Die Vasomotorisch Trophischen Neurosen Eine Monographie von *Dr R CASSIRER, Privatdozent an der* Universität Berlin Zweite umgearbeitete und vermehrte Auflage Mit 24 Abbildungen im Text und 24 Tafeln Berlin. S Karger 1912 Pp 988 Price 30 marks.

THE second *edition of Dr Cassirer's monograph* on vasomotor and trophic neuroses contains the results of numerous investigations during the last decennium on the difficult subject of which it treats. There is much, nevertheless, that remains obscure in the etiology and pathogenesis of such affections as Raynaud's disease, erythromelalgia, sclerodermia, acute circumscribed œdema, acroparæsthesia, and multiple neurotic cutaneous gangrene, which are the main topics of the monograph. Medical science is only beginning to realise the intimacy of the associations between the sympathetic system and the glands of internal secretion, and there is a wide field yet to be covered ere the chapter of the vasomotor and trophic neuroses can be completed.

Dr. Cassirer's monograph may be heartily recommended to the profession as an authoritative statement of the present state of our knowledge on the subject. An anatomical and physiological introduction of some 130 pages deals with the vasomotor tracts and centres, the secretory mechanism, and the vexed question of the trophic functions of the nervous system. The clinical descriptions of the various diseases above specified leave nothing to be desired. Their pathology and differential diagnosis are handled in a masterly fashion, although in a large volume like this we think room might have been found for more pathological illustrations. Nor should the reader omit the paragraphs on treatment; they serve their purpose well. A most extensive bibliography, probably the best that has ever been collected, and a series of fine X ray and coloured plates, materially enhance the value of the book. There is no index.

A Manual of Surgical Treatment. By Sir W. WATSON CHEYNE, Bart., C.B., D Sc., LL.D., F.R C S. Eng., F.R S, Honorary Surgeon-in-Ordinary to H M. the King; Senior Surgeon to King's College Hospital; and F. F. BURGHARD, M.S. Lond., F.R C S Eng., Surgeon to King's College Hospital and Senior Surgeon to the Children's Hospital, Paddington Green. New edition, entirely revised and largely rewritten with the assistance of T. P. LEGG, M S. Lond., F R.C.S. Eng., Surgeon to the Royal Free Hospital, Assistant Surgeon to King's College Hospital, and ARTHUR EDMUNDS, M.S Lond., F R C S Eng, Surgeon to the Great Northern Central Hospital, Surgeon to Out-patients, the Children's Hospital, Paddington Green. In five volumes. Vol. II. London, New York, Bombay, and Calcutta: Longmans, Green and Co. 1912 Pp. 570. Price 21*s.* net.

THE characteristics which distinguished the first volume of the revised edition of this work are equally conspicuous in the second part. The practical character of the information supplied is evident from a mere glance at the volume, and the practitioner cannot but benefit from possessing such a treatise to which he can refer as need arises.

The first section of this volume deals with the surgical affections of the soft parts, the skin, the subcutaneous tissue, the lymphatic glands and vessels, the fasciæ, bursæ, muscles, nerves, arteries, and veins; the second part includes the surgery of the bones; and the third is concerned with amputations. It will be seen that a wide range of subjects is dealt with, and in every matter the latest methods are described.

In a volume covering so much ground it is inevitable that there must be many points which offer themselves for discussion, and we may refer to one or two of these. In the account of the treatment of an aneurysm by ligature of the artery the following sentence occurs: "The older method was to apply the ligature immediately above the sac—'Auel's operation'"; and a little further on, after the mention of the objections to Auel's method, comes the sentence: "Therefore, the modification of ligaturing the artery at a distance from the sac, known as the 'Hunterian operation,' was substituted." Auel performed his operation in 1710, and Hunter employed his method for the first time in 1785; but there is not, so far as we are aware, any evidence that Auel's method was ever performed in the 75 years which intervened, except by Desault, who used it once in the very same year (1785) in which Hunter introduced his new method; and there is no evidence that Hunter had heard of Desault's operation. Hunter's method was devised, not as a substitute for Auel's method, but to replace the classical operation of Antyllus, which consisted essentially in tying the artery both above and below the aneurysm. Desault's case was perfectly successful, and therefore its result could have no influence in suggesting another operation. This is, perhaps, but a small point, but the idea that Hunter's operation replaced Auel's because of the bad results of the latter method is so firmly rooted in modern surgical literature that it is worth while to point out that it is not founded on fact.

Surely it is time that the word "scrofulous" should be allowed to die. If it is intended to be synonymous with "tuberculous" the latter word is more suitable, and if this is not intended the word is too indefinite in signification to be employed in medical science. We find here the expression, "scrofulous gummata," used; it would be far better to speak of "tuberculous nodules."

These are, of course, mere details. For the rest, it may be said that the views taken by the authors have always authority to support them, and the manual as a whole is a compendious and trustworthy guide to surgery.

A Treatise on Pellagra. By EDWARD JENNER WOOD, S.B., M.D. Chairman of the Pellagra Commission of the North Carolina Board of Health. London and New York: D. Appleton and Co. 1912. Pp. 377, with 38 illustrations in the text. Price, cloth, 16*s.* net.

THIS book is evidently the result of long and close study of the subject. It was begun, we understand, at a time when there was not a single treatise on pellagra in the English language except the short article in Clifford Allbutt's "System of Medicine" and that in the "Encyclopædia Britannica" Great attention has been bestowed by the author upon the work done by investigators not only in America but on the continent of Europe. In addition to much original matter the volume contains an abstract of the literature of the disease up to the present time from most of the foreign countries where pellagra is met with. It is of interest to note that Dr. Wood confesses himself as not being a believer in the maize theory of the causation of the disease, though he carefully discusses the etiology from the zeist as well as from the antizeist points of view.

The work is divided into ten chapters, in which are considered the history and geographical distribution of pellagra, the theories concerning its etiology, the general characteristics of the malady, the skin manifestations, the digestive disturbances, the nervous and mental changes which result, as well as the diagnosis, prognosis, prophylaxis, and treatment. The author, it appears, believes that pellagra is a parasitic disease, though he is not satisfied that the simulium, as claimed by Sambon, is the particular intermediate host in the transmission, but as to this he admits that the question is still *subjudice.* As respects the prophylaxis and treatment of pellagra Dr. Wood contends that they depend entirely upon the etiology of the disease, and until that is completely elucidated there can be no definite pronouncements. In the author's opinion, however, the malady can no longer be classed among the incurable complaints; it is not a self-limited disease, and unless vigorously treated from the beginning the same consequences must follow as in syphilis. He adds, "The therapeutic nihilist has no more right to treat pellagra than he has to treat syphilis." Much therefore depends upon an early diagnosis of the disease, for the most successful treatment is that which is begun early. Dr. Wood is inclined to regard favourably the use of preparations of arsenic.

The book is the work of a scholar who has long and carefully studied his subject, and the volume can be thoroughly recommended as a trustworthy treatise upon an obscure but important malady. As has already been said, it presents a very readable digest of the views of foreign authors, as well as giving in a succinct form many facts carefully collected in America by the author.

Selected Papers on Hysteria and other Psychoneuroses. By Professor SIGMUND FREUD, of Vienna. Authorised translation by A. A. BRILL, M.D., Clinical Assistant, Department of Neurology and Psychiatry, Columbia University. Second enlarged edition. New York: *Journal of Nervous and Mental Disease* Publishing Company. 1912. Pp. 215. Price $2.50.

THIS edition of Professor Freud's selected papers on hysteria has been enlarged by the inclusion of the essay on "wild" psycho-analysis, and of another on the future chances of psycho-analytic therapy. Thus completed, it presents to the English reader a very fairly complete view of both the earlier and the later contributions of Professor Freud to the subject of the psychoneuroses, enabling him to follow the development of the author's ideas and of the methods employed by him in psychotherapy. In the first of the two new papers Professor Freud maintains that the psycho-analyst uses, or should use, "sexuality" in the same sense as the word "love" in the English language, and holds that lack of psychic gratification, with various consequences, may exist where there is no lack of normal sexual intercourse. He deprecates the restriction of the subject to the somatic factor in sexuality, and points out various mistakes in technique committed by over-enthusiastic disciples of his school. In the second paper Professor Freud gives it as his opinion that considerable improvement in therapeutic results will ensue with further knowledge of method. He says that in the matter of the symbolism of dreams and the subconscious life "we actually discover something new every day." The latest discovery is that to dream of climbing a stair is a definite symbol of the sexual act. "Under rhythmic intervals and with increasing difficulty in breathing one reaches a height, and may come down again in a few rapid jumps." Other equally natural explanations do not apparently commend themselves to the author. Our readers will find on p. 1114 of this issue of THE LANCET an interesting article upon Professor Freud's theory of dreams, by Professor William Brown, of King's College, London.

The not always easy task of rendering into readable English the somewhat involved and occasionally elliptic style of the author has been satisfactorily accomplished by Dr. Brill.

Fortschritte der Naturwissenschaftlichen Forschung. Herausgegeben von Prof. Dr. EMIL ABDERHALDEN. Sechster Band. Mit 106 Textabbildungen. Berlin und Wien: Urban und Schwarzenberg. 1913. Pp. 268. Price, paper, 15 marks; bound, 17 marks.

A VARIED menu. The following subjects are presented: The Present Position of Investigation of Lakes—a continuation of the paper in Vol. VI. of W. Halbfass, of Jena. It extends to 72 pages, and deals with the topography, hydrography, and geology of the European lakes. Dr. V. Franz, of Frankfort, devotes over 30 pages to Comparative Neurology and Psychology. It cannot, however, be said that the contribution adds materially to our knowledge of this subject, though it fairly represents such knowledge as we possess as to the relation between the organisation of the nervous system and the psychical life of animals. The author, however, notes particularly that conscientious investigations have so far not led to the conviction that within the species homo sapiens the cultured civilised races possess a more convoluted or even a heavier brain than the less cultured uncivilised races. The author bases his assertion largely on the researches of Professor Kohlbrugge, published in 1911 (not in 1811 as set forth in the text). Professor Korschelt writes in an entertaining fashion about Pearls, giving an account of their structure, origin, and applications. The account occupies about 80 pages, and is both readable and informing; in fact, the story is well set forth in word and in pictures. Artificial and also vegetable pearls are included. G. Eichhorn, of Zürich, gives a short account of Recent Advances in Radiotelegraphy, while Professor Klaatch continues his presentation of the Origin and Acquisition of Human Characteristics. Nearly 70 pages are required to elucidate the author's account of the human foot and man's erect posture. The subject is treated more especially from the point of view of comparative and human anatomy.

A Text-Book upon the Pathogenic Bacteria and Protozoa for Students of Medicine and Physicians. By JOSEPH McFARLAND, M.D., Professor of Pathology and Bacteriology in the Medico-Chirurgical College, Philadelphia, &c. Seventh edition, thoroughly revised. With 293 illustrations, a number of them being in colours. London and Philadelphia: W. B. Saunders Company. 1912. Pp. 878. Price 15*s.* net.

PREVIOUS editions of this text-book have been reviewed at length in these columns, and the value of the work as a clear and comprehensive survey of its subject designed for the use especially of the medical man has been fully recognised. That its popularity is considerable is evidenced by the appearance of this, the seventh edition, which is very considerably increased, not only in bulk, but also in the range of its subject matter. The author in previous editions strictly confined his attention to bacteria, and further to those pathogenic to man. The pressure of the rapidly increasing knowledge of diseases caused by protozoa has broken down this conventional limitation and compelled Dr. McFarland, in order to make the work complete as an account of human infectious disease, to admit protozoal diseases to his book.

The growing literature of bacteriology and the resulting specialisation render it more and more difficult to keep a work on general bacteriology within bounds, but the author escapes from the difficulty, as in former editions, by writing especially for the student of human medicine and pathology. This leading idea, though the book is not a laboratory manual, involves such details of laboratory technique as are of service to the practitioner, and especially such as refer to the methods of diagnosis and treatment which grow out of the study of microbiology. The introduction of the protozoa has necessarily increased and altered the chapter dealing with structure and classification, and the completion of the book for the medical man has required the introduction of chapters on the determination of the phagocytic index and on the theory and technique of the Wassermann reaction. This last is very fully described and illustrated in its original form, and also in the modification due to Noguchi.

The second part of the work contains the usual descriptions of pathogenic micro-organisms, with the pathology of the lesions produced by them. The arrangement has been considerably changed since the fifth edition, and seems, indeed, to be rather haphazard. The protozoal diseases are grouped amongst the bacterial diseases and not treated separately. They include malaria, trypanosomiasis, kala-azar, yellow fever, amœbic dysentery, tropical ulcer, and histoplasmosis, this last an apparently new disease of the Panama Canal Zone. Amœbic dysentery is treated with unusual fulness. There does not seem to be any mention of the recent interesting work on anterior poliomyelitis, and in the description of African tick fever Leishman's work is omitted. The spirochæta pallida is dissociated from other spirilla. It is well described, especially with reference to methods of culture. In the chapter on actinomycosis there is not the importance attached to the anaerobic character of the organism found in human disease which is usual in American writings.

The work forms a handsome volume, well printed on good paper and well illustrated, though some of the photographs suffer from over-magnification of the organisms represented.

Infections of the Hand, a Guide to the Surgical Treatment of Acute and Chronic Suppurative Processes in the Fingers, Hand, and Forearm. By ALLEN B. KANAVEL, M D., Assistant Professor of Surgery, Northwestern University Medical School, Chicago. Illustrated with 133 engravings. London: Baillière, Tindall, and Cox. 1912. Pp. 447. Price 15*s*. net.

THIS book is composed of two parts; in the one are recorded a large number of experiments on the mode of spread of infections from one part of the hand to another, and an account is given of those anatomical relations which are of importance in the surgery of the hand. The second part applies these facts to the surgical treatment of sepsis of the hand and forearm. There are numerous illustrations showing the lymphatic and synovial spaces of the hand, and an examination of these will demonstrate clearly the reasons why infections of this region spread so rapidly. The site of the incisions required to deal with these infections must depend on the anatomical relations of the part, and the incisions must be rightly placed.

The importance of the hand justifies a very close study of the methods of treatment to be employed in infections involving it, and Dr. Kanavel's book will prove of service in enabling the practitioner to understand the reason of the treatment and in applying it with benefit to the patient. The functional difference between the results of a sepsis of the hand rightly and wrongly treated is very great, and too much attention cannot be bestowed on this subject.

Pathological Inebriety: its Causation and Treatment. By J. W. ASTLEY COOPER, L.R.C.P. & S. Edin., L.F.P.S. Glasg., Medical Superintendent and Licensee of Ghyllwoods Sanatorium. With Introduction by Sir DAVID FERRIER, M.D. Edin., F.R.S. London: Baillière, Tindall, and Cox. 1913. Pp. 151. Price 3*s*. 6*d*. net.

THE numerous works dealing with the medical aspects of alcoholic intemperance that have appeared within the last few years afford gratifying proof of the change that has come over lay and professional opinion with regard to the real nature of inebriety. Mr. Astley Cooper's modest volume is a useful addition to the literature, written under the influence of this new spirit. It deals, as is implied by its title, with inebriety conceived as a manifestation of some defect or disorder of nervous organisation; and though it is by no means easy to fix on the criteria by which cases of this sort are to be distinguished from cases of what, by contrast, we may term normal intemperance, the existence of such a type of neuropathic inebriety is a fact which will hardly be questioned by anyone who has had experience in this matter.

It is, of course, in its bearing on treatment that the recognition of this variety of intemperance has practical importance, for it obviously implies that mere isolation with enforced abstinence, or mere drug treatment directed to a hypothetical specific "drink crave," must be unavailing so long as the underlying nervous disorder persists. This is the view which Mr. Cooper seeks to enforce. He sets out in clear and simple language the methods of treatment which in his experience have given the most satisfactory results, and he points out that these results have been attained by supplementing the ordinary institution treatment by measures directed to the re-education of the will and the development of the power of self-control. The extent to which any such process of character-construction can be carried out is, of course, in many cases very limited, but it is encouraging to observe that those medical men who have had the widest experience in the use of psychotherapeutic methods are the least pessimistic in their view of the possibilities of treating inebriety with success. In agreement with most authorities, Mr. Cooper considers that suggestive treatment, on which he lays special stress, may in many cases be better administered in the waking state; when, however, it is desirable to produce hypnosis, he finds that the best results are got with the most profound degree of sleep that can be induced.

Building a Profitable Practice. By THOMAS F. REILLY, M.S., M.D., Professor of Applied Therapeutics, Medical Department, Fordham University, New York City. London and Philadelphia: J. B. Lippincott Company. 1912. Pp. 290. Price 10*s*. 6*d*. net.

THIS is a book on the practice of medicine from the business point of view as a means of livelihood. It is addressed to American medical men, and although a great deal that is contained in it will be found applicable to professional practice in this country, parts of it are not. Perhaps it is well that in England we take it for granted that attention to duty and reasonable capability are sufficient to ensure success. We also take it for granted that no special business instruction is needed, so we write no books and give no lectures on the making of profits. Dr. Reilly's book is concerned with the making of profits, and every aspect of the medical man's life is considered. There are chapters on post-graduate study, on hospital and dispensary practice, on furnishing and equipment, and on all details of the actual work of a practice, not omitting such intimate matters as the making of friends, personal manners and appearance, and marriage. The chapter on prognosis will be found very useful to the inexperienced man. He is certain to be questioned on this subject by his patients, and his success will depend in great measure on the correctness of his prognostication. The older and more trusted practitioner can often avoid questioning, but the young man is frequently nailed down. He will get much help from this chapter, particularly on that most difficult part of prognosis relating to death itself. The chapters on diagnosis and malpraxis are also very full of useful information, and that on the management of an obstetric case is one to read and mark.

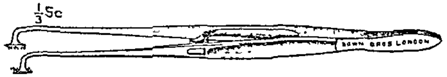
It has been said that the American puts into words what we on this side only think, but there are passages in this book which make us hope that some of the suggested counsel will fall on unintelligent ears. For instance, on p. 62: "When you are examining an applicant for admission to a secret lodge or fraternal insurance company, after routine examination look into the nose for spurs, polypi, or enlarged turbinates. ...... As lodge physicians are expected to give free medical attendance only, any surgical work that is required will be paid for at regular rates, and when you consider that almost every man has some trouble with his nose you will see the size of your field. *The problem before you is simply to convince him that the operation is necessary* and beneficial, and knowing this is true that should be a simple matter." Again, on p. 249 we read: "Soon after you have opened your office, the near-by druggist will probably present you with prescription pads with your name and address above and his own on the bottom or on the back of the page. Unless there be some favours shown to you by a certain druggist it is better to *tear off the name of the druggist from the bottom of the pad.*"

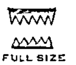
There can be no doubt that the newly qualified man is quite often unfitted to set up in practice for himself, even if he has spent one or two years in house appointments first. In the old days of apprenticeship it was different. He was taught how to "run a practice" and how to deal with people, both of which accomplishments are now allowed to come as they may. They come generally through assistantships and junior partnerships, or by the less pleasant way of costly experience. Perhaps it is better so. Books, however, have their place, and the book under review deserves to find a public; and although we should prefer to have seen some things omitted from it, we are bound to say that it contains a large quantity of very practical and good advice in subjects on which the medical man should be well informed.

New Inventions.

A NEW SPRING CATCH FORCEPS FOR TONSIL ENUCLEATION.

THE instrument illustrated below will be found of particular advantage in dealing with tonsils that are not easily accessible to the guillotine alone. The distinctive features are: (1) the blades curve sharply at right angles close to the jaws; the jaws open and close in the vertical plane, thus enabling the operator easily to get a firm grasp of the tonsil; (2) the jaws have short saw-shaped teeth, giving a firm hold and affording plenty of room between the blades when opened, an advantage in working in the small space available; and (3) the instrument passes conveniently through the fenestra of a guillotine or the loop of a snare.



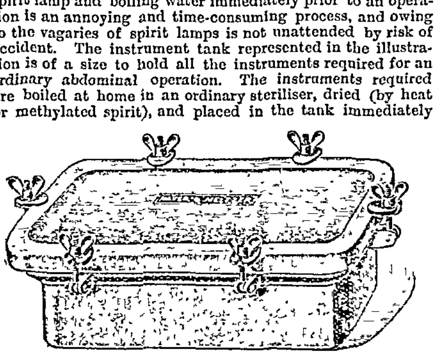


The makers of the instrument are Messrs. Down Bros., Limited, St. Thomas's-street, London, S.E.

Brighton. ARTHUR J. HUTCHISON, M.B., C.M. *Glasg.*

AN INSTRUMENT TANK.

THE sterilisation of instruments in private houses by a spirit lamp and boiling water immediately prior to an operation is an annoying and time-consuming process, and owing to the vagaries of spirit lamps is not unattended by risk of accident. The instrument tank represented in the illustration is of a size to hold all the instruments required for an ordinary abdominal operation. The instruments required are boiled at home in an ordinary steriliser, dried (by heat or methylated spirit), and placed in the tank immediately ready for use, immersed in methylated spirit, to which, if desired, a proportion of lysol can be added. Sharp instruments, such as knives, scissors, and needles, are kept in the tank permanently and need not be boiled. Ligatures may also be kept in the tank. Once in two or three weeks the instruments should be taken out and cleaned, especially if lysol is used, since it causes a greasy deposit to form upon them. It is also important to see that no blood or water gets access to the tank since in either case the instruments will rust. It should be noted that the tank is not intended for sterilising instruments by heating. It is simply used as a container. The top, sides, and bottom of the box are made of sheet copper. The whole strength of the box is concentrated in the circumference of the lid, which is a gun metal casting, and the top edge of the box itself, which is also cast in gun metal, and has upon its upper aspect all round a deep undercut groove into which a ring of hard rubber is forced by pressure. This groove corresponds with a V-shaped ridge within the lid which bites into the rubber and ensures a spirit-tight joint.



The instrument tank was made to my design by Messrs. Mayer and Meltzer, 71, Great Portland-street, London, W., and has been tested by two years' constant use in practice.

W. SAMPSON HANDLEY, M.D., M.S. Lond.

New Cavendish street, W.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MEETING OF COUNCIL.

A QUARTERLY meeting of the Council was held on April 10th, Sir RICKMAN J. GODLEE, the President, being in the chair.

The best thanks of the Council were given to Dr. Charles Hose for presenting some skeletons of adult orangs and other specimens to the Museum.

The Jacksonian Committee having adjudged the Jacksonian Prize for the year 1912 to the author of the dissertation on "The Embryology and Treatment of Cleft Palate" under the pseudonym of "Digamma," the PRESIDENT opened the envelope bearing this title, and declared that the enclosed name was Mr. F. W. Goyder, M.B. Cantab., F.R.C.S. Eng., of Bradford, and to him was awarded the Jacksonian Prize. It was decided to make the following the subject for the Jacksonian Prize for 1914: "The Pathology, Diagnosis, and Treatment of Trigeminal Neuralgia."

The Triennial Prize was awarded to Dr. W. Blair Bell for his essay on "The Anatomy and Physiology of the Pituitary Body and the Relationship with Disease of its Abnormal and Morbid Conditions." It was decided to make the following the subject for the Triennial Prize for the three years ending 1915: "The Human and Comparative Anatomy and Physiology of the Cerebellum."

The PRESIDENT reported that the Sir Gilbert Blane Medals had been awarded to Fleet-Surgeon Richard Cleveland Munday, H M S. *Hyacinth*, 1910, and Fleet-Surgeon Edward Sutton, H.M.S. *Highflyer*, 1911, both Members of the College.

Mr. M. F. Hopson, of Guy's Hospital, was elected a member of the Board of Examiners in Dental Surgery. Sir Rickman J. Godlee, the President, was re-elected a member of the Senate of the University of London for the ensuing four years.

Mr. EDMUND OWEN, Vice-President, reported the delivery of the Hunterian oration by the President. The best thanks of the Council were given to the President for his oration, and he was requested to publish it.

A report from Mr. C H. Golding-Bird on the proceedings of the Central Midwives Board was read, and the best thanks of the Council were given to him for his services as the representative of the College on the Central Midwives Board.

The name of a Member of the College was removed from the roll of Members in consequence of the issue of objectionable pamphlets and advertisements.

The PRESIDENT stated that Thursday, August 7th, had been fixed as the date of the conversazione at the College to the members of the Seventeenth International Congress of Medicine.

The SECRETARY reported that Surgeon-Major Henry Benjamin Hinton, of Adelaide, South Australia, admitted a Member of the College in the year 1835, had attained the age of 100 years on March 7th, 1913. It was resolved to send the congratulations of the Council to Surgeon-Major Hinton.

THE LANCET.

LONDON: SATURDAY, APRIL 19, 1913.

The Royal Commission on the University of London.

The Royal Commission appointed to inquire into the present state of university education in London issued their final report on Tuesday last, and the document is so drastic and at the same time so far-reaching in its nature that we do not propose at the moment to do more than deal with a few general aspects of the case. That any criticism of the findings and conclusions of the Commissioners should be in the least helpful, it is necessary that there should be a close appreciation of their arguments, for in every word of the report proof can be found that it is a closely reasoned document. The Commission was appointed four years ago and a very strong *personnel* was chosen, consisting of Lord Haldane, Lord Milner, Lord Justice Romer, Mr. Laurence Currie, Sir Robert Morant, Sir William M'Cormick, whose work in the cause of education in Scotland is well known, Mr. E. B. Sargant, the organiser of education in South Africa, and Mrs. Creighton. The absence, however, of a London graduate in medicine from this body was felt to be an unfortunate omission. The terms of reference of the Commission were to inquire into the organisation of the present working of the University of London, upon the facilities for advanced education offered by it, upon the proper provision that should exist for teaching and research, and upon the methods which would best combine into a progressive university the incorporated colleges, the Imperial College of Science and Technology, and other schools and university institutions concerned. A report made by such Commissioners upon so difficult a subject was expected to be a document of the first value to education, and this it is, whether we agree with all its findings or not For four years a small body of persons, well qualified, jointly and severally, to consider the general problems of education, have deliberated upon an extremely complicated problem, and in our opinion the result of their deliberations is both helpful and hopeful. That the report will cause apprehension and disappointment in some places, and even considerable chagrin in others, is undoubted. But to arrest the course of a long sickness painful remedies are very usually necessary, and valuable as much of the work of the University of London has been, there is no denying that it has for a long time been suffering from vagueness of aim, from want of coherence in its constituent parts, from poverty, and from multiplicity of antagonistic counsels. Should the recommendations of the latest Royal Commission be converted into an Act of Parliament with promptitude, and the necessary money be forthcoming, we believe that the University of London will shortly embark on a successful career; but there is no denying that many of those concerned in the education of the London medical student will find that the hardships of the position have not been sufficiently realised, and that any Bill framed upon the report will require modification in the light of their especially difficult circumstances.

The Commissioners have been unanimous in their recommendations, for which we cannot be sufficiently grateful. That this would be the case was, we think, foreshadowed by the character of the interim reports, which we have noticed on their appearance. Their main finding is that the whole organisation of the University as at present constituted is fundamentally defective, and not calculated to promote the highest interests of university education in London; and, further, they believe that it is not capable of developing on the present lines into a university such as the capital city of the Empire ought to possess. Such an expression of opinion sufficiently accounts for the sweeping nature of the advice which they give subsequently. The two main grounds of the defective organisation are stated to be:—first, that the present relations of the internal and external sides of the University are unsatisfactory; and secondly, that there exists in the University a combination of institutions differently related to it, and of different educational standard and aims, which cannot be made to work as a harmonious whole. Independent schools of the University, both general, professional, and technological, and "mixed" institutions in which a limited number of the teachers are recognised for University purposes, do not lend themselves to any known scheme of coordination. The want of money is not characterised exactly as a defect of organisation, but it is clear that some of the difficulties which have arisen in the past from the inability to secure harmonious grouping for bodies of divergent views and ideals might have been overcome, or greatly reduced, if the University had been in possession of substantial funds and had wisely administered them. We trust that the lesson here inculcated will be learned. Not only must money be found—the Commissioners suggest at least £99,000 per annum—but it must be spent upon the broad lines required for the realisation of the essentials of a university.

The question of medical education was found, as all our readers who are acquainted with its complications would have expected, to be one of the most difficult with which the Commissioners had to deal. The faculty of medicine has been treated by them, and rightly, as one apart, for the conditions of medical education, whether we consider the teacher or the taught, are not comparable to the conditions which prevail in other professional curricula. The Commissioners desire to see the preliminary scientific subjects form part of a school course; they propose no concentration into two or three institutes of instruction in anatomy, physiology, and pharmacology, recognising the obvious advantages of training the medical student in these early professional subjects at places where he is in touch with clinical and pathological work; and they recommend that university professors in the clinical subjects should be appointed, a recommendation that will entail the formation of university medical colleges

The whole subject of the organisation of a faculty of medicine in London is closely and fully considered in the report, a summary of which will appear in our columns. It should be added that the Commissioners find that the grievance of the London student, that he cannot obtain a medical degree upon reasonable terms, entitling him to the style of "Dr.," must be left to remedy itself through the provision of a proper faculty of medicine in the University; while they describe the question of a one-portal system for qualified medical men as outside their terms of reference. Divergent opinion with regard to the medical faculty is unreconciled by the report. The position of the external student in relation to that of the London medical student is still the debatable point; and we trust that those who debate it will show full appreciation not only of past events but of present urgent needs.

◆

The Physiological Bearings of New Sources of Fat Supply.

IT is desirable, we think, that the attention of our physiological authorities should be drawn to the rôle of fat in the dietary with special reference to a change occurring in the fatty substances that are being supplied in increasingly large quantities to the public. It is important to realise that the supply of fatty foods is being revolutionised by the introduction of many varieties of vegetable fats which hitherto have found little or no place in the common dietary. The fats at one time available for human use were chiefly the animal fats as represented by beef, mutton, pork, and butter fat, while the only vegetable fat consumed to any extent was olive oil. But now amongst the oils and fats which are included as edible are bean, nut, and seed oils, of which there is a great and growing variety. Cocoanut oil is perhaps the best example of what modern processes of extraction and refinement have done towards bringing vegetable fats into dietetic prominence. In a recently published work[1] upon the subject of the examination of fatty foods the authors say of cocoanut oil that it is used to an enormous extent in every form of foodstuff to which a solid fat may require to be added, that probably no other vegetable fat is so extensively used or adapted to so many purposes, and that its use is daily increasing as a constituent, not only of margarine, but of cakes, biscuits, and sweetmeats. Further, they state that at the present day there is scarcely an animal or vegetable fat, which can be procured in quantity, that has not been tried or actually used in margarine, and even fish oils are being pressed into the service of the manufacturer.

This displacement of animal fats by vegetable or other fats in the diet of the human race raises questions of great physiological importance. The business of the vegetable fat refiner is a lucrative one, and it is not, therefore, likely to shrink. It is a question whether the multifarious displacement which is signified by such commercial enterprise is justified by physiological considerations. We may well ask whether the vegetable fats possess a physiological efficiency equal to butter fat, whether they are as digestible, and whether, generally speaking, in fact, they are equally suitable for the human organism. We are not able to gather any distinct evidence upon the points where it is particularly desirable that such evidence should be obtained, having regard to the enormous quantities of vegetable fats now consumed by the public, when hitherto animal fats occupied the dietetic field in a practical monopoly. We may well express doubt that because any oil or fat is highly refined, deodorised, and bleached it is necessarily suitable for the purposes of human consumption. We remember, indeed, that not so long ago a consignment of oil was used for manufacturing margarine, with the result that the mixture proved to be a drastic purgative. The oil, in fact, was poisonous. We are impressed further by a contemplation of the fact that no food products present so much diversity in natural composition as do the oils and fats, a diversity of character which has made the analysis of oils and fats both prolific of method and uncertain in result. According to the authorities we quote, the examination of butter and margarine presents the most difficult problem which the analyst of oils has to face. When the extreme variation and complexity which may arise in the production of the latter and the wide natural variations of the former are considered, coupled with the fact that adulteration usually consists in the admixture of the one with the other in certain quantities, the difficulties will be appreciated. It is true that a knowledge of the products on the market, ruling prices, and direct information often enable the investigator to solve the problem of margarine mixtures with reasonable certainty, but there is in a large number of cases absolutely no method of arriving at proof that the constitution of any sample of butter fat is due to sophistication and not to natural causes. "This natural variation has brought the analyst," write Mr. E RICHARDS BOLTON and Mr. CECIL REVIS, "into the uncomfortable and unscientific position of having to fix limits of variation in dealing with butter fat, and the result, as always in such cases, is most unsatisfactory; but until some talisman be found which will distinguish the natural from the artificial this state of affairs will probably continue."

When it is recognised that these writers are experts upon the subject (one of them is, in fact, chief chemist to a large and well-known firm of dairy farmers), and that they have placed on record, in the book referred to, the results of many years' experience in the examination of edible fats, it is obvious that their observations cast doubt upon the value of chemical analysis as a means of effective control. The whole question of the supply of butter and butter substitutes, therefore, seems to us to call for careful special inquiry, inasmuch as the recourse to new fatty materials for the purposes of admixture may have a serious dietetic meaning for the public at large. To change our source of fatty foods from the cow to the cocoanut appears to us to be a policy which should not be left in the hands of manufacturers; the matter should be referred first to physiological authority. We have heard of a specimen of milk showing an excellent proportion of fat, which, however, on careful analysis was shown not to be milk fat at all, but foreign vegetable fat. We desire assurance that milk in which the natural fat has been replaced by a "hydrogenised oil" is physiologically equal to the normal mammalian secretion. Generally speaking, physiologists assert that the animal fats have a higher nutritive power than those derived from vegetables—suet, butter, and cream being regarded as the most serviceable of all. We have no evidence that this assertion has been controverted by scientific authority, and until that is the case the question of the suitability of the vegetable fats for human consumption or of their fitness to replace animal fats on all counts must be regarded as an open one.

---

Annotations.

"Ne quid nimis."

THE INTERNATIONAL CONGRESS OF MEDICINE.

THE Seventeenth International Congress of Medicine will be held in London this year from August 6th to 12th, inclusive, under the patronage of H.M. the King. H.R.H. Prince Arthur of Connaught has graciously consented to open the Congress as the representative of His Majesty. The opening meeting will be held in the Albert Hall at 11 A.M. on Wednesday, August 6th. The last meeting of the Congress in London took place in 1881, when Sir James Paget was president. This year the president is Sir Thomas Barlow, and the treasurers are Sir Dyce Duckworth and Mr. G. H. Makins. Sir Alfred Pearce Gould is chairman of the Executive Committee, Sir Henry Morris chairman of the Finance Committee, Sir Lauder Brunton chairman of the Reception Committee. There is also a Ladies' Committee, of which Lady Duckworth is chairman. The central office of the Congress will be located in the Albert Hall. The sectional meetings will be held in rooms in the University of London, the Imperial College, the Royal School of Science, the School of Art, and the Central Technical College. These bodies have generously placed their buildings, which are all close together in South Kensington, at the disposal of the Congress. The Royal College of Physicians, the Royal Society of Medicine, St. Thomas's Hospital, the Royal Army Medical College at Millbank, and the Royal Dental Hospital are also offering accommodation for sectional meetings. The Students' Union of the Imperial College will serve as the men's club, and the authorities of Alexandra House have kindly lent rooms for a ladies' club. There are in all 26 sections and subsections. Their sessions will be held in the morning and in the afternoon. The morning sessions will be devoted to discussions on fixed subjects, which will be introduced by eminent medical men from every part of the world, who have been specially invited for the purpose. The invitations have been very generally accepted, and there have been few disappointments. There seems no doubt that the discussions will be of great interest and importance. The work of the several sections will be noticed in future issues. Five general addresses have been arranged. These will be delivered by Professor Chauffard (Medicine), Professor Harvey Cushing (Surgery), Professor Ehrlich (Pathology), Mr. W. Bateson (Heredity), and the Right Hon. John Burns, M.P., President of the Local Government Board (Public Health). These will be delivered in the Albert Hall, where also will be situated the central offices of the Congress. It is estimated that there will be about 5000 medical men and 2000 ladies attending the Congress. The organisation of the Congress has been going on for nearly three years. It will give some idea of the magnitude of the task to state that it has taken a complete year to arrange the *personnel* of the various committees, and another complete year to settle the programme of the discussions in the sections. The latter was issued on Sept. 30th of last year.[1] There are several discussions for which two or more sections are combined. At the present time the reports drawn up by those chosen to introduce the discussions are being received and set up in type. It is hoped that all these reports, which will form the basis of the discussions, will be printed and bound as a separate volume for each section before Congress opens. A second volume for each section will be published subsequently containing the speeches delivered and the independent papers presented at the Congress itself. A circular will be issued on April 30th giving information on travelling facilities both to and in London, on hotels and boarding-houses, on the location of the various sections, and on other points likely to be useful to members. Early in June the final programme of the scientific business will be published, which will include the list of independent papers accepted by the sections, and the names of intending speakers. The office of the Congress is at 13, Hinde-street, W., where information may be obtained by applying to the general secretary. Subscriptions to the *General Fund of the Congress* should be forwarded to the treasurers of the Seventeenth International Congress of Medicine at the same address. It should be borne in mind that the membership subscription of £1 only suffices to meet the expenses of producing the volume of Transactions subsequently delivered to each member. The entire cost of organisation and conduct of the meeting has therefore to be provided for by private subscriptions to the general fund. A list of the subscriptions already received will be published shortly.

THE HOSPITAL WITH A MEDICAL SCHOOL.

IN an annotation which we published recently, dealing with the subject of ventral fixation of the uterus, the following sentence occurs: "We have always thought that the best test of the legitimacy, if we may so term it, and necessity for any operation is the relative frequency with which it is performed by the surgeons attached to a large general hospital with a medical school—that is, in those conditions in which competent and honest criticism is not likely to be lacking." This sentence has been made the subject of forcible criticism by a well-known London surgeon, whose desire to withhold his name is quite justified by the feeling that, not being on the staff of a hospital with a school, his words might be thought to be due to some feeling of resentment or disappointment. With regard to the particular operations under discussion or whether certain enthusiasts perform them with undue frequency (although strongly of the opinion that many patients are sufferers in this respect), he says little or nothing, his objects being to direct attention to the particular sentence quoted above. "Is not the writer," he asks, "rather overwhelmed by the importance of a position at a teaching school which has apparently narrowed his surgical horizon, and is he justified in claiming that the best test or criterion of the legitimacy or otherwise of any operative procedure is whether it is performed at a large general hospital with a teaching school? The reason adduced for this claim is that honest and competent criticism is not likely to be lacking." Taken from its context the sentence which has given rise to his communication appears to reflect in an unjust and unnecessary manner upon the numerous institutions which *do not* possess medical schools, but although the wording employed is not fortunate this was not the intention of the annotation. It is hardly necessary to point out that many of the advances of surgery in all its departments have resulted from the work in special hospitals without teaching schools. And it must be allowed that over-enthusiastic operators are to be found in large general hospitals with medical schools, in spite of any controlling influence which may exist. But the particular influence referred to was not the presence of the students. Criticism from the students who may, as our correspondent suggests, "naturally consider their teacher in the light of a king who can do no wrong," would not be of any help to a surgeon in deciding upon the employment of a particular procedure; but the criticism of colleagues in a large general hospital is always of the greatest value. All the numberless questions, medical, surgical, obstetrical, and biological, which may affect the advisability of adopting frequently some particular routine, can be debated with catholicity in a general hospital, while at a special hospital a narrower outlook must be taken. It is not the presence of the students that supplies the valuable collaboration which an operator may get at a large general hospital, but the presence of colleagues not engaged in the same special work. We are obliged to our correspondent for the courteous way in which he has brought the subject to our notice. The truth is that the general hospital and the special hospital alike have their places in our scientific evolution.

[1] THE LANCET, Oct. 19th, 1912, p. 1116.

THE UDAL TORRE SANATORIUM INCIDENT.

THE power of exacting strict discipline is so essential in a medical superintendent of a tuberculosis sanatorium that without it no amount of professional ability, experience, and industry will produce their full effect. At a time when sanatorium treatment was within the reach of the affluent alone this fact was conspicuously apparent, for the most successful medical superintendents were the martinets of more than military rigidity. There are plenty of reasons for this state of things—reasons which any intelligent observer of the interior economy of a sanatorium can formulate. And necessary as discipline is within a sanatorium where the patients are gently nurtured and more or less well educated, it is indispensable where many of them are neither. That is not to say that the same methods of maintaining authority will answer in the two cases. Far otherwise in fact; a greater fund of tact, and all that is summed up in the word character, will be required in dealing with the half-educated than with those who can signify their displeasure by withdrawing a patronage which is materially important. Now of all the "difficult" people to manage in a sanatorium, we can conceive of none so likely to get out hand as insured persons of Welsh nationality, especially when transferred to districts far from their friends and the land of their fathers. Docility was not exactly to be expected of all the patients at Udal Torre; but it would seem that the much talked of revolt was largely a matter of impulse rather than of preconcerted rebellion. A government inspector has investigated the whole matter, and his report shows that most of the alleged grievances were fanciful if not imaginary, though some of them are admitted to have had foundation. The report has evidently been drawn up after a full and fair examination, and may be accepted, we hope, as disposing effectively of the major criticisms which were levelled at the management of the sanatorium. Still, the fact remains that some of the patients got out of control; and with the multiplication of sanatoriums far and near in the land, it is not improbable that similar incidents may recur. The personality of the superintendent must always remain the best safeguard against indiscipline. But there is no way of assessing that elusive quality by examination tests; and no way of acquiring it, though no doubt a military training can help to cultivate it. In the nature of things, therefore, no rules can be laid down for the preservation of the right tone in a sanatorium. To quote a single instance in point, there is a system at a certain very well managed working men's sanatorium of serving the medical officers' table (and that of all the staff, in fact) with identically the same food as the patients themselves get. This effectively stifles baseless complaints about the kitchen department, for the patients can see the doctors' food taken from the same vessels as their own. Yet we doubt whether the plan is really sound, and certainly a forceful superintendent can get along without adopting it. So it is with every detail of sanatorium management: a strict disciplinarian can make his own rules, and no ready-made code will suffice to replace a strong personality at the head of affairs. If that lesson sinks a little deeper in, the storm in a teacup at Udal Torre may have done more good than harm.

IS YELLOW FEVER STILL ENDEMIC IN JAMAICA?

TIME was when yellow fever was almost continuously present in Jamaica, bursting out in epidemic form when any new body of troops or warships arrived at the island, but generally smouldering on in endemic fashion between the outbreaks. At the end of the eighteenth century the ravages of this disease were very great, the chief sufferers being the susceptible subjects who had lately reached the colony from Europe. About this time, it is stated by one writer of repute, there were "cut off" in four years among the European garrison no fewer than 3500 men, "chiefly from yellow fever." In recent years a great change has been wrought, and the malady has since been regarded as no longer existent in Jamaica. The last recorded outbreak occurred in 1897, when 76 fatal cases were certified, with nine more in the following year. From 1898 to 1912 only 10 deaths have been attributed to yellow fever in the island, the last fatal case being registered in 1904. In 1910 the late Sir Rubert Boyce, when writing upon yellow fever in the West Indies, said that vast improvements had been made in sanitary administration, with the result that endemicity of yellow fever in Jamaica had been stopped. The whole question has now, however, been re-opened by a report[1] presented to the Colonial Office by Captain T. J. Potter, R.A.M.C., who at the instance of the Jamaican Government made a special inquiry into "vomiting sickness," a name given by the natives to illness in which vomiting is a prominent symptom. The term, it may be added, has of late years been used even by local practitioners to indicate a febrile ailment in which vomiting is a leading feature. Captain Potter's inquiry showed that the so-called "vomiting sickness" occurs largely among the black population, and especially among black children, and that it is often fatal. During the first three months of 1911 he personally investigated upwards of 70 cases, some of which, however, were found to be instances of other diseases, such as cerebro-spinal fever, food poisoning, and the like; but there remained 38 cases, 21 of which proved fatal, that could not, in Captain Potter's opinion, be anything else but yellow fever. His conclusions were based, it appears, upon the clinical characters of the illness, and supported in certain instances by the post-mortem appearances. He therefore asserts that there is no justification for the use of the term "vomiting sickness"; it is not a clinical entity, and many of the cases so designated are actually yellow fever. One of the popular alternative names in Jamaica for "vomiting sickness" is "black vomit," a term closely identified with yellow fever, "vomito negro" being the usual name for that disease among the Spanish-speaking inhabitants of the shores of the Gulf of Mexico and elsewhere. As showing the amount of this so-called "vomiting sickness" that prevails in Jamaica, Captain Potter obtained a return which stated that during the first five months of 1911 no fewer than 223 cases came under observation, 126 of them being referred to one parish. Some of the facts collected by Captain Potter vary somewhat from the experience of other observers. The usual yellow fever season is said to be from April to September, but the cases recorded above by Captain Potter were mostly prior to that period of the year. Again, many authorities state that endemic yellow fever among the coloured races is generally a mild disease, especially in children; but we gather that in Jamaica many of those who are attacked are black children, and that a number of them die. On the other hand, there are some recorded facts which appear to support his views. For example, in an army departmental report published in 1908 reference is made to the occurence of a local five to nine days' fever in Jamaica, its leading characters being severe frontal headache, vomiting, an icteric tinge of the skin and conjunctivæ, and albumin sometimes found in the urine. Paratyphoid fever had been excluded, as also papataci fever, there being no phlebotomus flies on the island. It is unfortunately true that the symptoms and post-mortem appearances of yellow fever vary greatly in individual cases, and that none are sufficiently constant to be regarded as pathognomonic. So that the definite diagnosis of yellow fever, and especially among a black population, is attended with extreme difficulty. Up to the present time the specific organism of the disease has not been satisfactorily identified and isolated, so that bacteriological confirmation of the diagnosis cannot be maintained. It may be mentioned that the paraplasma flavigenum discovered by Dr. Harald Seidelin is being tested by other experts, but it is too early to say as yet that it is the parasite of yellow fever; if his claims be substantiated an enormous advance will be made and the diagnosis greatly aided. The opinion that yellow fever is still endemic in Jamaica has not been allowed to pass unchallenged by the medical men of the colony. In particular, Dr. Angus G. Macdonald,[3] medical officer of health of Kingston, the capital of the island, has with some vehemence disputed the conclusions of Captain Potter, dwelling particularly upon the absence of any typical examples among the alleged yellow fever cases investigated in the first quarter of 1911. He also suggests that possibly "vomiting sickness" may be due to a tick infection introduced into Jamaica since yellow fever disappeared. In this connexion he urges further investigation by local experts. It was obvious that so important a dispute could not be left in this undecided state, and it is satisfactory to learn that the Colonial Office has already ordered a further inquiry to be conducted by a commission of experts, and that bacteriological investigations will also be carried out on the spot.

A FOOD CONGRESS AT GHENT.

AN international exhibition is to be held in Ghent this year, and the occasion has suggested the convening of an international congress on questions relating to food adulteration. The date of this congress has been fixed for the first three days of August. The regulations under which the proceedings are to be conducted have been issued and an agenda of the subjects for discussion formulated. It is the view of the organisers that subjects should be approached not so much from a scientific as from a social standpoint. Amongst the topics which have already received a place for discussion are the protection of food substances from dirt, the regulation of the manufacture of table waters, the adoption of official methods of analysis for foods, the control of the sale of milk, the desirability of including in any scheme of education instruction about the nutritive values of foods, the question of the sale and production of foods in places where there may be persons suffering from infectious disease, the control of the use of preservatives, and the enforcement of regulations providing for the washing of glasses in public-houses. The work of the whole congress is divided into four sections: (*a*) chemistry, (*b*) hygiene, (*c*) popular education on food and cognate subjects, and (*d*) legislation. From a list which has reached us the congress has already received a distinguished patronage, including Government officials and members of the learned professions.

COXALGIA IN CHRONIC APPENDICITIS.

IN the *Maryland Medical Journal* for February Dr. Thomas R. Brown has discussed a symptom of chronic appendicitis which has received little attention—coxalgia. As chronic appendicitis is often attended by slight local symptoms, its diagnosis is difficult and depends on the correlation of many signs and symptoms, each of comparatively slight importance. Coxalgia occurs in a certain proportion of cases and is of great value in the diagnosis. The nature and extent of the symptoms of chronic appendicitis depend somewhat on the lesions in the appendix, which may take the form of adhesions, obliteration of the lumen, erosions, torpid ulcers, or cysts, but far more on the direction in which the appendix points, whether towards the gall-bladder, urinary bladder, or thigh, and on the association of the disease with splanchnoptosis, which Dr. Brown has found very common. There may be no local symptoms, and a clinical picture typical of neurasthenia may be presented or one of gastric or intestinal dyspepsia, or cholelithiasis or cholecystitis may be simulated, or the main symptom may be pain in the right hip or pain on micturition, or a combination of both. In a series of 20 cases of chronic appendicitis diagnosed as such and verified by operation Dr. Brown found that in three the main symptom was pain in the right hip (appendicular coxalgia). In one the pain was so intense and long standing, and so definitely related to exertion, that tuberculous coxitis was suggested. In each of the three cases there was splanchnoptosis of the highest grade, and the appendix, cæcum, and a portion of the transverse colon were tightly bound down to the abdominal wall and pelvic floor. In chronic appendicitis coxalgia may be absent altogether, or it may be absent when the patient is at rest and noted after walking and increased by flexion of the joint. The question arises, How can the coxalgia of chronic appendicitis be distinguished from that of latent tuberculosis of the hip-joint? In both there may be slight remittent pyrexia, rarely reaching 100° F. In the differential diagnosis skiagraphy after administration of bismuth is of paramount importance. In chronic appendicitis it shows *binding down* of the intestines in the cæcal region with sluggish motility and marked bismuth retention, the hip-joint being normal. Blood examination also is useful. Dr. Brown found a leucocytosis of from 10,000 to 16,000, though rarely exceeding 13,000, with neutrophiles from 75 to 85 per cent., in chronic appendicitis, while leucopenia with relative mononuclear increase occurred in tuberculosis. In one case the pain in the hip was so marked that several surgeons diagnosed coxalgia secondary to relaxation of the sacro-iliac joint. However, skiagraphy showed dense adhesions binding down the appendix, cæcum, and ascending colon to the lateral and posterior peritoneal surfaces. The abdomen was opened and adhesions over the head of the colon were divided. The base of the appendix was closely adherent to the cæcal wall. The appendix was directed posterior to the cæcum with its tip over the pelvic brim. It was found densely adherent throughout its whole extent, the tip being acutely flexed and bulbous. The ileum in its last three inches was kinked by a band of adhesions drawing it posteriorly and towards the cæcum. The appendix was removed, the adhesions about the ileum were released, and the resulting raw surface was covered as far as was possible without reproducing the kink in the ileum. An interesting point is the frequent association of chronic appendicitis without definite local symptoms with general splanchnoptosis. In considerably more than half of the 20 cases a greater or less descent of the abdominal organs was found, and in many this was very pronounced, so that the cæcum and a large portion of the transverse colon were below the pelvic brim. Whether the chronic appendicitis is primary or secondary to the ptosis of the intestines with the associated interference with the circulation and intestinal stasis, or whether the latter leads to a local peritonitis in which the appendix is involved, cannot be said. Not only was coxalgia the predominant symptom in three of the 20 cases, as stated, but it was present in many of the others. Hence coxalgia, especially if associated with splanchnoptosis, should suggest the possibility of chronic appendicitis with ileo-cæcal adhesions as the cause, and the case should be investigated on the lines described above. As to the cause of the coxalgia, it appears to be due to the mechanical effect of the dense adhesions. The direction in which the appendix points and the nature, extent, and position of the adhesions seem to be the determining factors whether coxalgia occurs or not.

[3] Is Yellow Fever Endemic in Jamaica? A paper read before the Jamaica branch of the British Medical Association in December, 1912. Presented to, and ordered to be printed by, the Mayor and Corporation of Kingston.

SIR THOMAS BROWNE ON SUPERFŒTATION.

THE report that the wife of a working man at Furness has given birth to children at an interval of six weeks between the two parturitions would not have appeared at all incredible in the seventeenth century. In his "Enquiries into Vulgar and Common Errors" Sir Thomas Browne stated his belief that hares were prolific through a habit of superfœtation. "An higher providence of nature," he avers, "especially promotes the multiplication of hares by superfœtation—that is, a conception upon a conception, or an improvement of a second fruit before the first be excluded, preventing hereby the usual intermission and vacant time of generation." Aristotle, Herodotus, and Pliny refer to this alleged fact, and "we have often observed," says Browne, "that after the first cast, there remain successive conceptions, and other younglings very immature, and far from their terme of exclusion. No man need question this phenomenon in hares, for the same often occurs in the case of women." "Although it be true," continues our author, "that upon conception the inward orifice of the matrix exactly closeth, so that it commonly admitteth nothing after; yet falleth it out sometime, that in the act of coition, the avidity of that part dilateth itself, and receiveth a second burden, which if it happen to be near in time unto the first, they commonly doe both proceed unto perfection, and have legitimate exclusions, periodically succeeding each other. But if the superfœtation be made with considerable intermission, the latter most commonly proves abortive; for the first being confirmed, engrosseth the aliment from the other." Julia, probably the wife of the young Marcellus and afterwards of Agrippa, and of Tiberius, is cited by Browne as a person fully cognisant of his theory of superfœtation. "The project of Julia seems very plausible, and that way infallible, when she received not her passengers before she had taken in her lading." Her lovers were Sempronius Gracchus and Julius Antonius, of whom Tacitus has something to say in his Annals. We, of course, mean no sort of disrespect to the mother in Furness when making mention of the notorious Julia.

POISONS IN DOMESTIC BOTTLES.

A CIRCULAR has been issued to sanitary authorities by the Local Government Board directing attention to the Order in Council prescribing that as from May 1st, 1913, all liquid preparations sold as carbolic or carbolic acid or carbolic substitutes or carbolic disinfectants containing not more than 3 per cent. of phenols shall be substances to which Section 5 of the Poisons and Pharmacy Act, 1908, applies. The Local Government Board have recently had under consideration the danger to life attending the distribution of poisonous liquid disinfectants—e.g., preparations of carbolic acid—in receptacles such as beer-bottles, ordinarily used for liquid intended for consumption. Instances have occurred of omission on the part of local authorities to observe, in the distribution of such disinfectants, the provisions in regard to the shape and marking of bottles made applicable to the retail sale of liquid poisons by the Poison and Pharmacy Act, and by regulations made by Orders in Council. It is pointed out that the precautions which are enforceable when carbolic acid or a liquid preparation containing it is sold should be observed generally in the gratuitous distribution of disinfectants by a local authority, or in the use of such by their officers, whether the preparation contains carbolic acid or any other poisonous constituent.

RUPTURE OF THE TENDON OF THE BICEPS DUE TO MUSCULAR ACTION.

In the *Gazette Hebdomadaire des Sciences Médicales de Bordeaux* of Feb. 9th Professor H. L. Rocher has reported a case of an unusual accident—rupture of the tendon of the biceps muscle due to muscular action. A printer, aged 46 years, while trying to lift a lithographic stone weighing 150 kilogrammes, suddenly felt something crack in his right arm, heard a sound like that of the tearing of cloth, and had the sensation of something running up the arm. He at once lost power in the arm as if it was broken. He supported the elbow at an acute angle with the left hand, because if he tried to extend it he felt acute pain. Eight hours after the accident he came to hospital. On examination he was a muscular man, with a swelling of the size of a mandarin orange in the middle of the arm on its anterior aspect. The swelling felt like muscle at rest and was moveable in all directions, but especially transversely. On active flexion of the elbow it ascended towards the shoulder and became more globular and firmer, without, however, attaining the firmness of muscle in a state of contraction. Below the swelling the forearm was abnormally flat as far as the elbow-joint. There was no ecchymosis or hæmatoma. All passive movements of the arm were normal, and only active flexion of the elbow-joint was lost. Rupture of the biceps tendon was diagnosed, and immediate operation was decided upon. Under chloroform a median incision was made in the lower half of the arm. The aponeurotic sheath of the biceps was intact. It was opened and found completely empty; the tendon, floating about, could just be perceived above. On drawing it down the muscular globe formed by the retracted biceps was found lodged in the upper part of the sheath and free from any tear. After careful examination of the bicipital tuberosity of the radius it was found that the tendon was not ruptured in its continuity, but torn off the bone. The end of the tendon was a little spread out.

It was cleanly torn off, and had not carried with it any fragment of bone. The tendon was reimplanted by means of three silk sutures which were passed through its extremity, and as low as possible through the aponeurotic sheath which accompanied the tendon to its insertion into the radius. The anterior aspect of the arm then assumed its normal appearance. The opening in the biceps sheath was united with catgut, and the wound in the skin was closed. The limb was supported with the elbow flexed at an acute angle. Union by first intention took place. The arm was kept in a sling for six weeks, so as not to stretch the scar in the tendon. Then massage and electrical treatment were adopted. Six weeks later the biceps, which had diminished to half its normal size, had regained three-quarters of its volume, and its power was progressively returning.

THE POTATO.

THOUGH the poisonous alkaloid and glucoside known as solanine is a normal constituent of the healthy potato, references to toxicological literature fail to furnish any decisive evidence that the tuber has caused any widespread or serious illness. In these days, when alarming symptoms of poisoning may sometimes be traced to food in which, for some mysterious reason, the poisons known as ptomaines have elaborated themselves, it is just as well when searching for the *fons et origo mali* not to forget the potato, for under certain conditions solanine may be found in unusual quantity, and this alkaloid may set up the usual disturbances which are characteristic of an irritant poison. In the normal potato the amount seldom exceeds 0·01 per cent., but this may easily be exceeded in the diseased potato. Sprouting potatoes seem to contain a more than usual quantity of alkaloid, while it is also more likely to be present in the immature potato. Thus the potato residues, consisting probably of sprouting potatoes, from a distillery have been found to be responsible for the occurrence of poisonous symptoms in cattle, and solanine was separated from the mash by analysis. It appears to occur in larger proportion in the peel, so that there may be reasons for avoiding the "jacket." Though not very soluble in water it is probable that boiling removes some of the alkaloid. As we have stated, however, there is little in toxicological records which amounts to a serious indictment against the potato, and the small doses which occur are stated by some authorities to be an excellent sedative, more efficacious in long-standing neuralgia, especially when neuritis is present, than either antipyrine or antifebrin. We have little doubt that oftentimes a judicious diet of potatoes would be of greater benefit to a good many self-physicking people than a dose of some antipyretic substance which they regard as adapted to relieve all headaches whatsoever their origin.

A TYPHOID CARRIER STATE IN RABBITS.

THE importance of the part played by typhoid carriers in the spread of the disease among mankind is now generally recognised, and consequently any light that can be thrown on this condition by experimental research, and especially anything tending to indicate the best method of treating such carriers, is of much clinical interest. In a paper recently published in the *Journal of Medical Research*[1] Dr. John Anderson Johnston records some results obtained in artificially producing in rabbits a "carrier" condition. He inoculated these animals intravenously with a suspension of typhoid bacilli in saline solution and then examined their blood and fæces for signs of infection. The organisms began, as a rule, to appear in cultures from these materials in from seven to ten days; indeed, in two instances a diarrhœal affection started within two days and the bacilli were found in the stools. The rabbits were then vaccinated with dead cultures of the organisms, and the bacilli disappeared within a space of 30 to 60 days from the original inoculation. Of seven vaccinated animals which came to necropsy five were entirely negative with respect to cultures of these bacilli, while the two from which they were obtained had both died within a short time of being treated. On the other hand, of 11 vaccinated animals all but one showed the presence of bacilli, though five did not harbour them in any part except the gall-bladder. Similarly, in two animals in which the bacilli had disappeared, so far as cultures from the blood and fæces went, during life, puncture of the gall-bladder gave positive results. It is thus shown that in the rabbit, as in man, the gall-bladder is a seat in which the organisms may persist when they have elsewhere vanished. Further, in two animals in which the bacilli could no longer be found in the fæces the administration of a dose of ox bile, which caused an attack of diarrhœa, was followed by their reappearance, just as catarrhal conditions of the bowel may in man give rise to renewed excretion of typhoid bacilli in the stools. From these experiments it would seem that vaccination is indicated in all cases in which a carrier state exists in human beings, and that careful examination of the fæces should be made in all cases of typhoid fever, just as the throat is swabbed after an attack of diphtheria, to ascertain that the organisms have ceased to be excreted by this route and that the convalescent is no longer, so far as can be discovered, a source of danger to others.

Dr. William Brown will give a public lecture on Abnormal Psychology at King's College (University of London) on Wednesday, April 23rd, at 4 P.M. Professor W. D. Halliburton will be in the chair.

FREUD'S THEORY OF DREAMS.[1]

BY WILLIAM BROWN, M.A. OXON., D.SC. LOND.,
HEAD OF THE PSYCHOLOGICAL DEPARTMENT, KING'S COLLEGE,
UNIVERSITY OF LONDON.

I.

WHEN the secretary of the Listerian Society very kindly invited me to read a paper on something of medical interest connected with the science of psychology, Professor Sigmund Freud's psychiatrical system at once occurred to my mind as the most suitable theme for such a discourse. Not only are his views winning ever wider acceptance among leading psychiatrists of all nationalities at the present day and justifying themselves by practical results, but they are also very good illustrations of the help which strictly psychological methods of thought may bring to the science and art of medicine.

Theoretically the connexion between psychology and medicine must be a very close one. Only on the theory of materialism can its importance be denied. According to this view psychical process is merely the result of physiological process occurring in different parts of the cerebral cortex. All mental disease would therefore be merely the effect of cerebral disease, and consequently attempts to cure by mental methods would involve the absurdity of treating the symptoms of the disease and not the disease itself. But by far the greater number of thinkers qualified to pass a reasoned judgment upon this question of the relation of mind to brain agree in rejecting the materialistic view. The two other alternative theories of the relation—viz., interactionism and parallelism, both give great scope for the use of mental methods in therapeutics. This is obvious in the case of interactionism, according to which the mind is an entity distinct from and partially independent of the brain, exhibiting laws of action not entirely identical with the laws of brain activity But it is equally true for parallelism The theory of psycho physical parallelism states that there is a point to point correspondence between changes in certain parts of the cerebral cortex (and possibly other parts of the brain) and changes in consciousness For every occurrence in consciousness there is some corresponding physiological change occurring in some part of the brain There is, however, no relation of causality between the physical and the mental series of events Rather are these series to be regarded as different sides or aspects of the same real process But if this be so, change in the real process can be produced from without—i e , by external agency—from either of its two sides, the physical or the psychical, indifferently Mental disease is also cerebral disease, but it is quite as legitimate to attempt to produce a change on the mental side by mental means as to produce a physical change by physical means A mental change, *eo ipso*, involves or brings along with it a corresponding physical change in the brain and *vice versâ*

---

[1] Journal of Medical Research, November, 1912, vol. xxvii., No. 2, p. 177.

[1] A paper read before the Listerian Society at King's College Hospital on Jan. 21st, 1913

Whichever theory we adopt, one thing at least is clear—namely, that our knowledge of mental processes is very much more precise and complete than our knowledge of the corresponding processes in the cerebral cortex, and explanations of mental disturbances in terms of memory ideas, imaginations, desires, and wishes are really more logical than those in terms of hypothetical nerve cells and nerve fibres so beloved by some physiologists It is quite possible, and on the parallelist hypothesis it is more than probable, that ultra microscopical changes in the cerebral cortex accompany all cases of so called functional mental disease, where gross lesions of the brain have not hitherto been demonstrated, but ignorance of them need not deter us from formulating psychological theories which may justifiably claim to explain the changes that *are* observable—viz , the mental disturbances of the patient

It may cause surprise to some of my hearers that I have chosen Freud's Theory of Dreams as the special subject of my paper, but I have done so for very good reasons In the first place, it is a fact, emphasised again and again by Freud himself, that this theory is the central core of his whole system of psychiatry, and the one that during the lapse of years he has found least reason to modify It is through a study of dreams that we can alone arrive at an adequate and direct appreciation of the nature of the *unconscious* and of its significance for the conscious mental life In the second place, the now famous method of "psycho analysis," introduced by Freud and elaborated into a definite technique by Jung, is most easily understood and most convincingly justified in Freud's scheme of dream interpretation, in which it plays a prominent part Finally, dreaming is a normal function of the mind and may therefore be safely discussed by a psychologist who can lay claim to no first hand knowledge of pathological cases Yet if Freud's theory be true that dreams are formed according to the same fundamental laws that produce the symptoms of hysterical patients, a careful study of the former must add very considerably to the intimacy and effectiveness of our knowledge of the latter A psychologist is only entirely within his own domain when he is face to face with facts of consciousness These he can only observe within himself, and his dreams (together with what is added to them by psycho analysis) may therefore give him an insight into the nature of hysteria which according to any other theory of the disease must be denied him so long as he remains normal

The outlines of Freud's theory of dreams are well known Every dream is the fulfilment of some wish In the great majority of cases the wish is one that has been repressed by the waking consciousness, and its fulfilment in the dream is disguised according to rules that are both complicated and diverse It is for these reasons that the general law has so long escaped notice, and scientists have been so ready to deny all significance to dreams This state of things is inevitable so long as attention is restricted to the dream [illegible] constitutes its meaning, and when discovered by the method of psycho-analysis is found invariably to be the fulfilment of some wish The manifest content is made up of memories from the past life of the dreamer, patched together in apparently quite random order and according to the most superficial laws of association The laws of rational connexion, especially those of causation, which dominate waking consciousness, seem to be in abeyance, and in their place the only laws of connexion observable are those of association by contiguity and association by similarity As a general rule the memories most commonly aroused are those of the "dream day" (the day before the dream) and those of early childhood Memories of the dream-day form part of every dream without exception Actual bodily disturbances, either of the external sense organs or of the internal organs are, when not too intense, incorporated in the dream though in a disguised form In this way every dream may be regarded as fulfilling at least one wish—viz , the wish to go on sleeping If these actual stimuli were recognised for what they are the dreamer would no longer be asleep but awake, and this is what happens when they become too intense Thirst arising during sleep may produce the dream experience of drinking water in huge draughts In this way are fulfilled the two wishes, to continue sleeping and to drink Other bodily needs arising during sleep may receive imaginary satisfaction in the same way Instances like these illustrate very clearly the function of dreams in acting as the guardians of sleep

Freud relates an amusing story of a medical student who was very fond of his bed, and could only with the greatest difficulty get up in time for his work at the hospital One morning on being called by the maid, who shouted through the door, "Get up , you must go to the hospital," he half awoke, and then proceeded to dream of a ward in the hospital in which he found himself lying upon a bed with a card hung over the head of it stating his name, age, and occupation Remarking to himself "Since I am already in the hospital I do not need to get up and go there," he turned over and continued his sleep

Numerous instances may be quoted in which the fulfilment of a wish appears in the dream in clear and undisguised form The dreams of young children are almost invariably of such a nature Desires, of which the satisfaction has been denied them during the day, again and again appear as fulfilled in the dreams of the following night This kind of evidence is obviously of the highest importance for the theory of dreams, since the child's consciousness shows the laws of mental process in their simplest and most fundamental forms The wish fulfilments of adults are as a rule expressed somewhat less directly, even when they do not belong to those unconventional and consequently "repressed" forms which will engage our attention more fully presently Recently, while working for a medical examination which it was most important that I should pass at the very first opportunity and for which I had been able to find very little time for preparation, I dreamt one night that someone showed me the examination paper, although it was some days before the date of the examination Not until some time after the dream did I realise its true significance and its connexion with my intense desire to pass On another occasion, while anxiously waiting for the appearance of certain reviews which I had written for one of the daily newspapers, I dreamt that I received yet another batch of books from the same source This dream was evidently a slightly indirect fulfilment of my wish that the other reviews of mine had not miscarried and would shortly appear

Instances of such clear wish fulfilments in dreams must be frequent in everyone's experience, and it may with some degree of plausibility be objected that they do not necessitate any theory more elaborate than the one most generally accepted—viz , that dreams are simply the revival, in chance order, of memories aroused during the condition of sleep For the imagined fulfilment of wishes may reappear as memories, just as other forms of consciousness do Freud, however, does not admit this, since he finds that every kind of dream, whatever the nature of the memories which unite to form its "manifest content," shows under the treatment of psycho analysis a clear reference to the fulfilment of a wish or wishes, which often gives the dream an entirely new aspect

The method of psycho analysis is simply a method of free association The subject whose dream is being interpreted is asked to adopt the mental attitude of meditative expectancy, and in this frame of mind to consider the parts of the dream one after another and say just what ideas spontaneously occur to him in connexion with each. It is essential to the success of the method that he should rigidly keep in abeyance any tendency to criticise, modify, or reject any of these ideas as they arise, and that he should make a faithful record of all of them, however absurd or objectionable some of them may appear to be. The ideas which thus arise by free association will be found all to converge to one system of ideas concerned with the fulfilment of a wish. This system of ideas is the "latent content" of the dream, or the "dream-thought," and gives the dream its meaning and its *raison d'être*. The wish involved in it is one that is not in harmony with the conventional and ethical ideas of the developed personality, and is therefore entirely repressed during waking consciousness and can only attain realisation in the dream consciousness of sleep in underhand and roundabout ways which have still to be described.

The repressing factor in the waking consciousness is named by Freud the *endopsychic censor*. The term is somewhat figurative, but lends itself well to the purposes of vivid description. In sleep this censor is still active, though not to the same degree nor with the same watchfulness. If only the repressed wish can disguise itself sufficiently, it may succeed in slipping past him unnoticed, and so rise into the half-light of dream consciousness. Before discussing in detail the various ways in which the wish may accomplish this disguise, and which Freud classifies under the general heading of *Traumarbeit*, or dream work, I will give a description of one of his own dreams, together with a summary of its psycho-analysis.[2] I must, however, first summarise his preliminary explanation which alone makes the dream intelligible.

Freud heard in 1897 that two professors of his university had proposed him for the position of professor extraordinarius, election to which he doubtless greatly desired. After receiving this news, and on the day before the dream, a colleague, who had for some time waited without result for the success of his own nomination to a similar professorship, visited him and told him that he had at last gone to a high authority about the matter and had learnt that his non-success was due to his religion and nationality. Freud suffered from the same disadvantages, and so might on this score draw but a discouraging conclusion from the news as to the probable fate of his own nomination. "On the morning after this visit," writes Freud, "I had the following dream ...... I. Friend R. is my uncle. I feel tender affection for him. II. I see his face somewhat altered before me. It is, as it were, drawn out lengthwise, a yellow beard which surrounds it stands out with exceptional clearness."

At first Freud was inclined to dismiss the dream as an absurdity, but remembering that in the case of his own patients this tendency often indicated that the meaning of the dream was a disagreeable one and such that the person was loth to admit even to himself, he proceeded to analyse it, pondering over it sentence by sentence and noting what ideas occurred to his mind while doing so. It then became clear to him that the face was, as it were, a composite photograph of the friend of the previous evening's conversation and one of his uncles, who had been unfortunate enough to come within the arm of the law. His father was in the habit of attributing this uncle's downfall not to wickedness but to weakmindedness. Consequently the dream purports to say that his friend R. is weakminded or stupid, like his uncle. Further reflection brings to light the memory of a conversation with another colleague who had likewise been unsuccessfully nominated for professor and who attributed his failure to an accusation brought against him by one of his patients. The courts had dismissed the charge as entirely unfounded and malicious, but the incident could not fail to injure his prospects. The meaning of the dream is now clear. The uncle represents just those two colleagues of Freud who had been unsuccessful in their nominations for professorships. By disingenuously insinuating that one of them is stupid and the other a criminal the dream clears the way for the success of Freud's own nomination, since on these assumptions the fact of his religion need not weigh against him. The dream represents the *wish* that this might be the real state of affairs—a wish that Freud would not for a moment entertain in the waking state or even in manifest form in a dream.

The tender affection experienced in the dream still needs explanation, since it is much more pronounced than that which Freud had ever felt for his uncle or for his friend. Reflection shows that it does not belong to the latent content. It is directly contrary to this content and eminently adapted to hiding the full significance of the dream-thought from the dreamer himself. This indeed is its real purpose. By changing the appropriate feeling-tone of the latent content into its opposite the wish has succeeded in evading the censor and achieving its own dream-fulfilment.

Other ways in which the latent content may disguise itself are by transferring the feeling-tone from one part of the manifest content to another, by altering the emphasis of different elements in the manifest content, so that a prominent element corresponds to an unimportant part of the latent content, and conversely, and, above all, by the use of symbolism. This symbolism is, to some extent, different for different persons, and also for different nationalities, since it partly depends upon the chance associations of experience and upon the similarities of words representing different objects. But some symbols would seem to be common to the majority of people, especially in matters connected with sex. Sexual relations may be represented by walking up and down stairs, by flying, or by journeying in a train or other vehicle. Entering into water may symbolise, by opposites, the fact of birth. Hats and shoes in dreams often have reference to sex. Many other symbolisms are met with which are too obvious to need mention here. Freud records the case of a woman who dreamt that she saw her fifteen-year-old daughter lying dead in a box, in which psycho-analysis showed that the latent content of the dream was a wish dating 15 years back that the child might die before it was born. This is a good illustration of the way in which wishes may persist for years in the unconscious uninfluenced by later experience.

In Freud's opinion a very large proportion of the repressed wishes which realise themselves in the dreams of adults originate in early childhood. They are also, he thinks, predominantly sexual in nature, the sexual mental life of the child beginning much earlier than scientists have generally supposed. The sexual inclinations may find their earliest objects in the parents, and then undergo vigorous repression as the result of further development and education. These repressed wishes may show themselves later in dreams, or, when very strong and very firmly repressed, may give rise to more serious symptoms. The attraction is accompanied by feelings of hatred and jealousy towards the parent of the opposite sex. These are repressed in the same way and for the same reasons, and may in later life produce dreams of the death of the father or the mother, as the case may be.

The legend of Œdipus, who unwittingly marries his own mother, Jocasta, and, though guiltless in intent, pays the penalty for this unholy act, is a mythical representation of this general tendency in human nature. Freud would explain the mystery of Hamlet in the same way. Hamlet is unable to take vengeance on the man who has supplanted and murdered his father because he himself in his early youth had wished his father's death. The wish has been vigorously repressed and he is at present unconscious of it, but it still exists in his unconscious and produces the inhibitory effects depicted in the play. Freud considers that repressed wishes of this nature are the principal factor in the production of all the psychoneuroses.

If we bear in mind that children's ideas of death are very vague and in most cases correspond simply to "permanent absence," the theory is not so outrageous as it might otherwise seem to be. The "naturalness" of family affection has undoubtedly been greatly exaggerated by earlier thinkers, and the passions of hostility aroused within the family circle are often very fierce. As the children grow up these feelings generally disappear and make way for the more conventional and intellectualised forms of sentiment, but deep down in the unconscious recesses of their souls persist the traces of earlier conflicts.

It may be thought surprising that such an immoral wish as that of death should ever succeed in passing the censor and attaining to a dream-fulfilment. Two facts sufficiently explain it. In the first place the wish is the last in the world that we should ever consciously entertain, and for this reason the censor is unprepared for its appearance. In the second place the wish-fulfilment is accompanied in the dream by a feeling of intense sorrow which seems to receive a sufficient explanation in the anxiety for the person's welfare which the dreamer has genuinely felt in more recent times, especially during the dream-day, and which might be expected to persist as a memory in the dream. The real source of the sorrow is the fact that the censor has been overpowered.

---

[2] See Traumdeutung, dritte Auflage, S. 100-104.

These considerations suggest the probable explanation of all forms of *anxiety dreams*, which are accompanied by pain, and seem therefore in such flagrant contradiction to the wish theory. Freud writes:—

> The anxiety dream only occurs when the censor is partly or entirely [illegible] *forms of painful feeling* (p. 195).

And again in another passage (p. 171), distinguishing two types of anxiety dreams:—

> On the one hand, the anxiety in the dreams may be a psychoneurotic [illegible]

I have quoted these passages in the author's words because they are so crucial for his whole theory both in its psychological and in its pathological aspects. For my own part, and on the basis of my own experiences, I find it very difficult to agree entirely with this explanation. It may not be special pleading, but it seems very much like it. Why this persistent and almost impertinent faithfulness to one idea? Are not fears just as primitive as wishes and just as capable of repression without annihilation? May we not broaden the basis of our explanatory system? Freud has considered these and other possibilities, and on the basis of experience rejects them. But it is difficult to see how experience can force us to the wish-explanation when the huge class of anxiety dreams require such complications of the theory before they can be brought into line with the others.

In this connexion I might mention a striking experience of fear-repression with persistence in the unconscious that happened to me about a year ago. One day while out hunting I had two bad falls in rapid succession, but in the excitement of the chase felt none of the organic disturbances of fear, much to my own surprise. That night I dreamt of the entire hunt from start to finish, but with the intensest fear. My heart felt literally in my mouth the whole time. Even now the feeling sometimes recurs at [illegible] feel nothing of it and have [illegible] am of this kind in terms of [illegible] ter part of the theory, the repression, is well illustrated by it. Freud's theory would fall much more completely into line with the views of modern psychology if in it he replaced "wish" by "emotional or instinctive tendencies." Examples of such emotional tendencies are fear, anger, self-assertion, self-abasement, and disgust, and systems of ideas tinged by these emotions may be on occasion driven from the main consciousness into the unconscious and reappear, under certain conditions, in dreams.

II.

We have still to consider Freud's theory of dream-synthesis as distinguished from dream-analysis. Many different kinds of processes may be detected in the *Traumarbeit*, or dream work. In the first place there are those processes of disguise adopted by the latent content which I have in outline already described. Secondly, there are [illegible]

Logical connexion in general in the latent content is represented by simultaneity in the manifest content. The relation of causality may be represented either by a mere succession of dream images or by an observable transformation of one into another. In the first case the succession is often between one dream and the next. Similarity is represented by unification, in the form either of identification or of a composite picture. These expressions of similarity often serve to represent a *desired* similarity. Relations are often represented in the manifest content in a reversed form; even in the succession representing causality the effect is frequently put before the cause. The explanation of this is, of course, the desire to evade the censor. Lack of clearness in the dream often represents actual uncertainty in the dream thought. One of Freud's patients at first refused to relate her dream to him "because it was so indefinite and confused." Finally, after some persuasion, she said "that there were several persons present in the dream, herself, her husband, and her father, and that she didn't seem to know whether her husband was her father, or who her father really was, or something of that sort." The explanation was that she was expecting a child, and that her friends had been bothering her to know "who exactly the father was." Evidently in such a case as this the lack of clearness is really a part of the dream-thought.

There are two general characteristics of dreams which deserve special mention. One is "*condensation*" (Verdichtung), where, through appropriate choice of material for the manifest content, the dream expresses the fulfilment of several wishes in one short dream experience. The manifest content chosen is as it were a nodal point or a number of nodal points from which important trains of association lead in different directions to eventually reach and sustain a number of wish-fulfilments. Each part of the manifest content is overdetermined, so that "*overdetermination*" (Ueberdeterminierung) is simply the other aspect of condensation. The second characteristic is that of "*displacement*" (Verschiebung), and has already been mentioned in another connexion. It consists in a shifting of emphasis or of psychical intensity from one part of the dream to another, "a transvaluation of all values" as Freud calls it, and produces a distortion of the dream which helps the repressed wish to evade the censor.

A tendency towards the rationalising of the manifest content along lines different from those of the hidden wish-fulfilment may often be detected in a dream, and may also continue to exert an influence on it after waking. This is what Freud has named "secondary elaboration," and is, of course, the work of the censor. The influence of the censor is also to be seen in the tendency to forget one's dreams, which may even extend to the interpretation of them. One may wake up from a dream [illegible] and fall to sleep again, and [illegible] dream and interpretation are [illegible] sufficient to refute Dr. Mort [illegible] forgetting of dreams is simply a special instance of the forgetting of dissociated states of consciousness. The forgetting is an active process of repression similar to the repression which first drove the wish into the unconscious.

All dreams, without exception, are egoistic. They are the fulfilment of wishes of an entirely selfish nature. In dreams where the dreamer himself does not seem to be present, it will be found that he is represented by some other personage. If several of these are present the ego is to be identified, thinks Freud, with the one who carries the "affect."

Professor Freud has worked out an elaborate psychological system to explain the phenomena of dreams and psychoneuroses, which I deal with more fully in a later section of this paper. Like many other psychologists, he regards the "psychical" as something very much wider than the "conscious." Of the latter he writes: "Consciousness appears to us to be a sort of sense-organ, which perceives a content given from elsewhere" (p. 105). This content, when not illuminated by consciousness, may yet persist as an unconscious psychical process. But Freud makes a new and important contribution to psychological theory in distinguishing between two kinds of unconscious ideas, to which he gives the names "*foreconscious*" and "*unconscious*" respectively. Describing the mind as a sensori-motor system made up of subsidiary systems or "instances" he writes:—

> The last of the systems at the motor end we call the *foreconscious*, in order to indicate that the excitation processes taking place within it can rise to consciousness without further hindrance, provided that certain conditions are fulfilled—e.g., the attainment of a certain intensity, a certain distribution of that [illegible] is [illegible] as attention, and so forth. It [illegible] the sys[illegible] hol[illegible] to voluntary movement. [illegible] because it has no access [illegible] during which [illegible] alteration (p. 382).

Put quite briefly, the distinction would seem to be one between repressed and unrepressed memories. The "unconscious" contains those tendencies experienced, or at least existent, during our past life, especially during the early years of childhood, which have been energetically repressed, and the censor, which is the allegorical name for this repression, is therefore situated between the unconscious and the foreconscious. That is to say, the censor is itself unconscious (or foreconscious), although at the time when the repression of the infantile tendencies first took place it may have been conscious. Freud also inclines to the view that there is some evidence for the existence of a second censor between the foreconscious and the conscious.

Now it is the foreconscious which furnishes the material of the "manifest content" of our dreams, and in it may be found not only wishes, but fears, anxieties, hopes, and all the other conative tendencies displayed by the mind. On the other hand; the unconscious contains wishes, and wishes only. These date from early childhood and are always sexual in nature, since no other wishes would have met with the vigorous repression necessary to drive them into the unconscious. Freud brings forward some interesting arguments in favour of this theory of the fundamental nature of wishing in early life. Unfortunately space does not allow me to discuss them here as they deserve.

The wishes of the adult consciousness, even when repressed, are in Freud's view seldom intense enough to serve single-handed as the motive to the formation of any dream, and in most cases, if not in all, need the coöperation of unconscious infantile wishes. It is these latter which supply the requisite energy, although themselves remaining hidden until revealed by psycho-analysis. They transfer their psychical energy to corresponding elements in the foreconscious and so attain to a vicarious fulfilment. The only wish derived from the foreconscious which is a primary constituent of any dream is the wish to continue sleeping, and this wish is an essential part of every dream. It might perhaps be regarded as an infantile wish which has never been repressed and has never undergone modification in the course of mental development.

(To be concluded.)

ANNUAL REPORT OF THE LONDON COUNTY COUNCIL FOR 1911.[1]

(*Concluded from p. 1047.*)

IN a leading article in THE LANCET of March 15th on the Vital Statistics of London we announced the intention of further considering Dr. W. H. Hamer's contribution to this report, only a partial notice of which was then possible.

Typhoid Fever.

Among several matters of medical interest, Dr. Hamer's account of the behaviour of typhoid fever in London is particularly noteworthy. In the course of the last 20 years numerous explosive outbreaks of this disease have occurred in different parts of the metropolis, the cause of which was in most cases traced to infected food. In some instances suspicion seemed to attach to shell-fish, in others to ice-cream, to fried fish, or to watercress.

The present report strikingly illustrates the difficulty of discriminating between one and another suspected food-supply, and is therefore deserving of attentive study. It is reassuring to learn that efforts are now systematically made by local medical officers of health to trace the source of infection wherever typhoid fever attacks are reported. According to the local reports a large number of fever cases appear to have been imported, most of these giving a history of seaside or foreign infection. The difficulty of diagnosis is emphasised in some of the reports, and this difficulty is illustrated by the return of cases certified as typhoid fever and admitted to the hospitals of the Metropolitan Asylums Board. From a table it appears that during the last 10 years the proportion of these cases wrongly diagnosed as typhoid fever has varied annually from 18 to 38 per cent. In the course of the year 1911 nearly one-third of the cases admitted were eventually declared to have been erroneously certified.

Investigation into Typhoid Fever Prevalence in London.

About the middle of September a marked increase of typhoid fever was observed in different parts of London. In Finsbury alone 30 cases were reported in a single week, the number notified in the preceding five weeks having averaged less than 1 per week.

In the annual reports of the medical officer of health of Finsbury for 1910 and 1911 special reference is made to certain localised prevalences of typhoid fever and to possible sources of infection. For example, the suggestion is made that hawkers suffering from incipient typhoid fever while selling watercress or fruit may be a means of spreading infection. A further possibility suggested is the existence of undiscovered carriers of typhoid fever. In considering the exceptional prevalences referred to, question arose as to whether certain cases of typhoid fever occurring in other parts of London may have been due to the same causes as those operative in Finsbury. The matter was therefore referred by Sir Shirley Murphy, then his chief, to Dr. Hamer for special investigation, and his report (which is reprinted in the present volume) was presented to the County Council at the time.

At the outset careful examination was made of the usual media of typhoid infection. Milk, to which, of course, attention was directed, was readily exonerated. The possibility of contamination of water mains was next considered, but the distribution of attacks lent no support to such a hypothesis. The age-constitution of the sufferers in this outbreak was remarkable, children and young adults between the ages of 5 years and 25 being, with few exceptions, the victims. Moreover, the sufferers were exceptional socially. The exclusive selection for attack of persons at certain ages and of a particular social class practically negatived the probability that either water or milk was accountable for the outbreak. On the other hand, the rapidly growing conviction that either fried fish or ice-cream was at fault received further confirmation thereby. Among other articles of food, shell-fish and watercress came under scrutiny, but very few of the sufferers had consumed either of these articles of food; moreover, the mussel season had at that time barely commenced.

In submitting to the Council the results of Dr. Hamer's investigation, Sir Shirley Murphy remarked that "*primâ facie* there were some grounds for suspecting that the outbreak might possibly have been due to ice-cream; but an analysis of all the evidence failed to show any other explanation than the consumption of fried fish as the cause of the prevalence." The ground on which ice-cream was at first suspected as a possible source of mischief was the fact that about one-third of the sufferers had purchased ice-cream from one particular vendor. But it was subsequently proved that 35 of the 56 sufferers had not partaken of ice cream at all. On the other hand, no fewer than 52 of the 56 infected persons had consumed the suspected fish. Moreover, careful study of the age-incidence and topographical distribution of the sufferers, and of the purchasers of fried fish at the particular shop, yielded strong evidence in support of the fish infection theory; and this evidence was further strengthened by the fact that there were numerous instances among families where a single person bought suspected fish and was alone attacked, whilst among families sharing fish in common multiple attacks supervened. It may here be affirmed that the presumption that the whole fish-supply at this period fell under suspicion has never been made in the course of this investigation. Dr. Hamer's report dealt fully with the question of the particular consignment of fish probably at fault, and made it clear that it was only the cheaper portions of fried fish sold to the early evening customers on a particular date in August that could properly be suspected. It is probable that the infected fish was distributed, not in Finsbury alone, but in two other boroughs also. The records of onset of illness pointed to August 17th or 18th as the date of delivery in London of the infected consignments of fish. It is important to note that some of the fish deliveries referred to were from unusual sources, owing to dislocation of traffic caused by a strike. It was stated at the time that on this account trawler owners on the coast found it impossible to dispose of the boat catches at the end of the preceding week. Dr. Hamer draws attention to the important fact, established by the inquiries and reports of officers of the Board of Trade, that much of the small plaice sold at Billingsgate comes from certain "nursery ponds" not far from the mouth of the Elbe. It is possible that "estuary fish" may be in question in the present case.

---

[1] Previous notices of this report appeared in THE LANCET of March 15th, p. 764, and April 12th, p. 1045.

Previous Outbreaks of Typhoid Fever

The County Council reports of past years contain evidence of several previous outbreaks of typhoid fever in London apparently caused by fried fish, and the recent occurrence at Finsbury adds another to the list. In his annual report for 1910 Sir Shirley Murphy epitomised the facts respecting these outbreaks. It is there stated that as far back as the year 1900 three localised prevalences of typhoid fever occurred in Southwark, in one of which 120 persons were attacked. Dr Hamer obtained evidence implying that the Southwark prevalence was due to infected fish and, further, that two other prevalences (in Lambeth and Kensal Town) were probably due to a similar cause. In 1903 the same origin was assigned for certain prevalences of typhoid fever in Holborn and in Southwark, and in 1906 there was some evidence pointing in the same direction. In 1908 fish again fell under suspicion in Bethnal Green and in Shoreditch. In 1910 Bethnal Green was yet again visited this time more severely. In this case examination showed that every one of the 49 sufferers from typhoid fever obtained fried fish from one or other of three specified shops, two of which derived their fish supply from a common source. Almost simultaneously with this latter outbreak 33 local prevalences of typhoid fever occurred in various parts of London and in Tottenham and Edmonton. After exclusion of the ordinary sources of mischief it was found in all these instances that the sufferers had partaken of fish (frequently fried), and that these were usually small plaice, known among fish vendors as "late steamer fish". Very great are the chances against such a combination of circumstances as the foregoing being the result of mere coincidence.

Tuberculosis in London

The campaign against tuberculosis continues to be carried on systematically in the metropolis, and as a result the loss of life from this eminently preventable disease still continues to decrease. Compulsory notification of pulmonary tuberculosis is now in full operation throughout the county. Under a general order of Nov 15th 1911, the Local Government Board issued a further series of regulations respecting this subject. These regulations complete the system of notification inaugurated in 1908 and medical practitioners are now required to notify to the sanitary authority every case of pulmonary tuberculosis occurring in the course of their public or private practice.

Referring to the issue during the year of the Final Report of the Royal Commission on Tuberculosis, and especially to the declaration of the Commissioners that more ample powers than they now possess are needed by the County Council for the exclusion of tuberculous milk from London, the report proceeds to show that in the interval between the inauguration of the Council's General Powers Act in 1907 and the end of 1911 between 7000 and 8000 samples of cows' milk have been examined, the result being that 10.8 per cent. of those samples were found tuberculous. The milk came from 28 different counties, not all of them near London. Since the Act came into force the Council's veterinary inspector has visited 1622 farms and inspected 44 307 milch cows, of which 1.3 per cent. were found to be affected with tuberculosis of the udder. It is satisfactory to learn that the owners concerned have undertaken to discontinue the sale for human consumption of the milk of the animals thus affected. All the animals in London cowsheds are examined by a veterinary surgeon about six times yearly under the provisions of the Act of 1904, by which the Council is authorised to seize and slaughter any cow suspected to be suffering from tuberculosis of the udder. During the year under notice 18 animals were seized and slaughtered under the Act and compensation was made to the owners, post-mortem examination having shown in each case that the udder of the animal was tuberculous.

Cerebro spinal Fever

Under the Public Health (London) Act, 1891, the Council made an order extending for a further period of 12 months from March, 1911, the notification of cerebro-spinal fever (epidemic cerebro-spinal meningitis) occurring within the county. Arrangements have been perfected whereby the County Council receives from medical practitioners particulars of all cases coming under observation. This information is promptly communicated to the several medical officers of health, who thus receive warning of cases occurring in other districts, and facilities are afforded for observation in event of the disease showing a tendency to spread. During the year under notice 101 cases of this disease were reported, bringing up the total since 1907, when notification first became compulsory, to 642 cases. The notification of this disease, as well as of acute poliomyelitis, is now permanent.

Housing of the Working Classes

A history of the housing question in London up to the year 1900 has already been published[2] by the Council, and an account of the Council's housing work since that date is now in course of preparation.

In the present report particulars are given of the powers of the Council for the housing of the working classes. Part I of the Act of 1890 imposes on the County Council the duty of demolishing and reconstructing unhealthy areas that are large enough to be important to the whole county. It also imposes on them the necessity of providing for the re-housing of persons of the working class displaced by such demolition. Part II empowers the borough councils (and in their default the County Council) to deal with individual obstructive houses, or with smaller insanitary areas of merely local importance. Under Parts I and II the County Council has already completed 13 schemes involving the displacement of more than 16 000 working class persons and the re-housing of 15 000 of the persons displaced. Under the Housing and Town Planning Act 1909, facilities are given for dealing, by way of demolition, with such dwelling houses as are so dangerous or injurious to health as to be unfit for human habitation, the power to make the necessary orders for this purpose being entrusted by that Act to the local authorities instead of to the courts of summary jurisdiction as formerly. The expenditure by the County Council up to March 1912 in respect of the clearance of insanitary property amounts in the aggregate to nearly £3 500 000. In carrying out public improvements other than schemes under the Housing Acts the Council has displaced more than 12 000 persons, and has provided suitable accommodation for nearly 13 000 in lieu of the properties demolished. The Council has already erected three model lodging houses for men, containing 1856 cubicles, but on account of the still persisting deficiency of such accommodation it has recently provided in various parts of London a number of tenements capable of accommodating 4068 persons. In addition, it has acquired four suburban estates—at Tottenham, Tooting, Norbury, and Hammersmith—comprising 340 acres. Up to the end of the year under notice, 2405 cottages accommodating 17,831 persons, had been completed on these estates, making a total accommodation for nearly 22 000 persons provided under Part III of the Act.

ROYAL MEDICAL BENEVOLENT FUND

As previously announced, the King was graciously pleased last year to confer on the Fund the title of "Royal". To celebrate this event it has been arranged to hold a dinner of those interested in the Fund and its Guild—ladies and gentlemen. H.R.H. Prince Arthur of Connaught will preside over the dinner which will take place on Wednesday, April 30th, at the Hotel Cecil. The following is the second list of stewards:—

Acland, Dr. T. Dyke
Alexander, Dr. F. W.
Baker, Dr. J. C.
Brownfield, Mr. H. M.
Chapman, Dr. C. W.
Cock, Mr. F. W.
Cook, Mr. H.
Clayton Greene, Mr. W. H.
Edge, Dr. A.
Finlay, Prof. D.
Flower, Mr. G. W.
Freyer, Mr. P. J.
Gardner, Dr. H. W.
Godlee, Lady
Godson, Dr. Clement
Green, Dr. W. G.
Griffith, Mr. J.
Gubbins, Surg.-Gen. Sir W.
Hay, Dr. K. R.
Hewitt, Sir Frederic and Lady
Hovell, Hon. Mrs. Mark
Howarth, Mr. G.
Lawford, Mr. J. B.
Lett, Mr. Hugh
Lowe, Mrs.
Luce, Dr. R. H.
Macnaughton Jones, Dr. H.
Mann, Dr. A.
Porter, Surg.-Gen. Sir James

[2] The Housing Problem in London, 1855-90 (No. 503).

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 96 English and Welsh towns with populations exceeding 50,000 persons at the last Census, and whose aggregate population at the middle of this year is estimated at 17,852,766 persons, 8293 births and 5195 deaths were registered during the week ended Saturday, April 12th. The annual rate of mortality in these towns, which had been 16·5, 16·9, and 15 6 per 1000 in the three preceding weeks, further declined to 15·2 per 1000 in the week under notice. During the 13 weeks of the quarter just ended the mean annual death-rate in these towns averaged 16·9 per 1000, against a corresponding rate of 17·5 in London. The death-rates last week in the several towns ranged from 7·5 in Tottenham and in Edmonton, 7·7 in Coventry, 7·9 in Carlisle, 8·2 in Croydon, and 8·3 in Willesden and in Hornsey, to 22 7 in Gloucester and in Stoke-on-Trent, 24·3 in Halifax, 26·7 in St. Helens, and 27·9 in Stockton-on-Tees.

The 5195 deaths from all causes in the 96 towns were 142 fewer than the number in the previous week, and included 394 which were referred to the principal epidemic diseases, against numbers declining from 464 to 402 in the four preceding weeks. Of these 394 deaths, 213 resulted from measles, 63 from infantile diarrhœal diseases, 50 from whooping-cough, 36 from diphtheria, 19 from scarlet fever, and 13 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 1·2 per 1000, and coincided with the rate in each of the two preceding weeks. The deaths attributed to measles, which had been 220, 208, and 215 in the three preceding weeks, were 213 last week, and caused the highest annual death-rates of 2·0 in Bolton and in Stockton-on-Tees, 2·1 in Smethwick, 2·2 in Wolverhampton, 2·3 in West Bromwich and in Wigan, 2·4 in Newport (Mon.), 3·1 in St. Helens, and 5·2 in Gloucester. The deaths of infants (under 2 years of age) referred to diarrhœa and enteritis, which had been 67, 71, and 53 in the three preceding weeks, rose to 63 last week, and included 16 in London, 7 in Liverpool, 4 in Stoke-on-Trent, 4 in Walsall, 3 in Birmingham, and 3 in Nottingham. The fatal cases of whooping cough, which had declined from 83 to 60 in the four preceding weeks, further fell to 50 last week; 15 deaths were registered in London, 5 in Liverpool, 3 in Stoke-on-Trent, and 2 each in Birmingham, in Oldham, in Leeds, and in Aberdare. The deaths attributed to diphtheria, which had declined from 54 to 35 in the five preceding weeks, were 36 last week, and included 11 in London, 4 in Stoke-on-Trent, 4 in Manchester, 3 in Leeds, 2 in Cambridge, and 2 in Leicester. The deaths referred to scarlet fever, which had been 28, 19, and 23 in the three preceding weeks, were 19 last week, of which number 4 were recorded in London, 3 in Birmingham, and 2 in West Ham. The fatal cases of enteric fever, which had been 13, 8, and 16 in the three preceding weeks, slightly fell to 13 last week, and included 3 in Manchester and 2 in Liverpool.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospitals, which had steadily declined from 2112 to 1410 in the 15 preceding weeks, had further fallen to 1357 on Saturday last; 148 new cases were admitted during the week, against 156, 168, and 167 in the three preceding weeks. These hospitals also contained on Saturday last 872 cases of diphtheria, 811 of measles, 264 of whooping-cough, and 38 of enteric fever, but not one of small-pox. The 1287 deaths from all causes in London were 129 fewer than the number in the preceding week, and were equal to an annual death-rate of 14·9 per 1000. The deaths referred to diseases of the respiratory system, which had steadily declined from 453 to 346 in the six preceding weeks, further fell to 285 last week, but were 59 above the number recorded in the corresponding week of last year. The deaths attributed to influenza numbered 45, against 65, 47, and 45 in the three preceding weeks.

Of the 5195 deaths from all causes in the 96 towns, 177 resulted from different forms of violence, and 384 were the subject of coroners' inquests. The causes of 42, or 0·8 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Leeds, Bristol, West Ham, Portsmouth, Salford, Cardiff, Bolton, and in 59 other smaller towns. Of the 42 uncertified causes of death, 4 were registered in Birmingham, 3 in Stoke-on-Trent, 3 in Liverpool, 3 in Gateshead, 2 in Gloucester, 2 in Bury, and 2 in Newcastle-on-Tyne.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns with an aggregate population estimated at 2,259,600 persons at the middle of this year, 1196 births and 746 deaths were registered during the week ended Saturday, April 12th. The annual rate of mortality in these towns, which had steadily declined from 20·7 to 17·2 per 1000 in the six preceding weeks, was again 17·2 per 1000 in the week under notice. During the 13 weeks of the quarter just ended the mean annual death-rate in these Scotch towns averaged 19·1, against a corresponding rate of 16·9 per 1000 in the 96 large English towns. Among the several towns the death-rates last week ranged from 10·7 in Ayr, 11·9 in Perth, and 12·0 in Kilmarnock, to 20·8 in Greenock, 21·6 in Coatbridge, and 22 0 in Dundee.

The 746 deaths from all causes were 2 in excess of the number in the previous week, and included 83 which were referred to the principal epidemic diseases, against numbers declining from 88 to 75 in the three preceding weeks. Of these 83 deaths, 44 resulted from whooping-cough, 13 from measles, 11 from infantile diarrhœal diseases, 9 from diphtheria, 3 from enteric fever, and 3 from scarlet fever, but not one from small-pox. These 83 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·9, against 1·2 per 1000 in the 96 large English towns. The deaths attributed to whooping-cough, which had been 55, 44, and 43 in the three preceding weeks, were 44 last week, and included 25 in Glasgow, 8 in Edinburgh, 4 in Greenock, and 2 each in Leith, in Motherwell, and in Hamilton. The deaths referred to measles, which had been 5, 9, and 8 in the three preceding weeks, rose to 13 last week of which number 5 occurred in Glasgow and 4 in Aberdeen. The fatal cases of diarrhœa and enteritis (among infants under 2 years of age), which had been 18, 17, and 13 in the three preceding weeks, further declined to 11 last week, and included 5 in Glasgow and 2 in Dundee. The deaths attributed to diphtheria, which had been 3, 7, and 6 in the three preceding weeks, rose to 9 last week and comprised 5 in Glasgow, 3 in Aberdeen, and 1 in Greenock. The 3 deaths referred to enteric fever were equal to the number registered in each of the two preceding weeks, and were recorded in Aberdeen, Paisley, and Coatbridge respectively; the 3 fatal cases of scarlet fever, which coincided with the average in the three preceding weeks, were registered in Glasgow, Aberdeen, and Leith respectively.

The deaths referred to diseases of the respiratory system, which had been 166, 154, and 127 in the three preceding weeks, further declined to 117 last week; 31 deaths were attributed to different forms of violence, against 17 and 27 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland, with an aggregate population estimated at 1,199,180 persons at the middle of this year, 716 births and 517 deaths were registered during the week ended Saturday, April 12th. The annual rate of mortality in these towns, which had been 21·7, 23 8, and 23·3 per 1000 in the three preceding weeks, further declined to 22·5 per 1000 in the week under notice. During the 13 weeks of the quarter just ended the mean annual death-rate in these towns averaged 22·2 per 1000; in the 96 large English towns the corresponding death-rate did not exceed 16·9, while in the 16 Scotch towns it was equal to 19·1 per 1000. The annual death-rate last week was equal to 27 2 in Dublin (against 14·9 in London and 18·0 in Glasgow), 19·6 in Belfast, 24·5 in Cork, 14·0 in Londonderry, 19 0 in Limerick, and 20·9 in Waterford, while in the remaining 21 smaller towns the mean death-rate did not exceed 20·7 per 1000.

The 517 deaths from all causes in the 27 Irish towns were 18 fewer than the number in the previous week, and included 37 which were referred to the principal epidemic diseases, against 46 and 39 in the two preceding weeks. Of these 37 deaths, 14 resulted from measles, 10 from infantile diarrhœal diseases, 5 from scarlet fever, 5 from diphtheria, and 3 from whooping-cough, but not one from small-pox

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING THE YEAR 1912.

(*Specially compiled for* THE LANCET.)

Cities and Boroughs.	Estimated population in the middle of 1912.	Notified Cases of Infectious Disease.												Deaths from Principal Infectious Diseases.									Deaths from all causes.	Death-rate per 1000 living.†

* Including membranous croup. † The death rates are corrected for variations in sex- and age-constitution of the populations of the several boroughs, the population of England and Wales being taken as the standard.

or from enteric fever. These 37 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·7 per 1000; the death-rate from these diseases last week did not exceed 1·2 in the 96 large English towns, while in the 16 Scotch towns it rose to 1·9 per 1000. The deaths attributed to measles, which had been 14, 17, and 14 in the three preceding weeks, were again 14 last week, and comprised 8 in Wexford, 3 in Newry, 2 in Belfast, and 1 in Cork. The deaths of infants (under 2 years of age) referred to diarrhœa and enteritis, which had been 7, 8, and 11 in the three preceding weeks, were 10 last week, and included 5 in Dublin and 3 in Belfast. The 5 fatal cases of scarlet fever, of which 3 occurred in Dublin and 2 in Belfast, were 3 above the average in the three preceding weeks. The 5 deaths attributed to diphtheria were equal to the average in the three preceding weeks, and comprised 4 in Dublin and 1 in Belfast. The 3 deaths referred to whooping-cough were registered in Dublin.

The deaths in the 27 Irish towns referred to diseases of the respiratory system, which had been 138, 122, and 142 in the three preceding weeks, declined to 109 in the week under notice. Of the 517 deaths from all causes, 158, or 31 per cent., occurred in public institutions, and 10 resulted from different forms of violence. The causes of 17, or 3·3 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 96 large English towns the proportion of uncertified causes of death last week did not exceed 0·8 per cent.

VITAL STATISTICS OF LONDON DURING 1912.

IN the accompanying table statistics of sickness and mortality in the City of London and in each of the metropolitan boroughs are summarised for the year 1912. With regard to the notified cases of infectious disease it appears that the number of persons reported to be suffering from one or other of the ten diseases specified in the table was equal to a rate of 5·3 per 1000 of the population estimated at 4,519,754 persons in the middle of the year; in the three preceding years the rates had been 6·6, 4·5, and 5·4 per 1000 respectively. Among the various boroughs the rates last year ranged from 3·4 in the City of Westminster, 3·6 in the City of London, 3·7 in Kensington, and 3·8 in Hampstead and in Stoke Newington, to 6·5 in St. Pancras, 6·9 in Bermondsey, 7·2 in Deptford, 8·4 in Woolwich, and 8·5 in Greenwich. The cases of small-pox notified during the year numbered 4, against 21, 7, and 63 in the three preceding years; of these 4 cases, 3 belonged to Woolwich and 1 to Poplar. The prevalence of scarlet fever showed a slight increase, 11,312 cases being notified in 1912, against 10,489 in 1911. Among the several metropolitan boroughs the greatest proportional prevalence of this disease was recorded in Fulham, Stepney, Bermondsey, Deptford, Greenwich, and Woolwich. The number of scarlet fever patients admitted into the Metropolitan Asylums Hospitals was 10,488 last year, against 16,183, 9889, and 9631 in the three preceding years; 2088 cases remained under treatment at the end of the year, against 2329, 1574, and 1878 at the end of the three preceding years. Diphtheria was somewhat less prevalent last year, 7101 cases being notified, against 7389 in the preceding year; this disease was proportionally most prevalent in Hampstead, St. Pancras, Holborn, Greenwich, Lewisham, and Woolwich. There were 6184 diphtheria patients admitted into the Metropolitan Asylums Hospitals last year, against 5799, 4882, and 6336 in the three preceding years; 959 patients remained under treatment at the end of the year, against 904, 827, and 1294 at the end of the three preceding years. The prevalence of enteric fever showed a marked decrease last year; 704 cases were notified, against 1284 and 1025 in the two preceding years. Among the several boroughs this disease was proportionally most prevalent in Holborn, Bethnal Green, Stepney, Poplar, Southwark, Bermondsey, Lambeth, and Wandsworth. The number of enteric fever patients admitted into the Metropolitan Asylums Hospitals was 381, against 539, 745, and 552 in the three preceding years; 37 cases remained under treatment at the end of the year; 62, 88, and 76 at the end of the three preceding years. The greatest proportional prevalence of erysipelas occurred in Finsbury, Shoreditch, Bethnal Green, Stepney, Poplar, Southwark, Bermondsey, and Deptford. The 380 cases of puerperal fever notified during the year included 31 in Stepney, 30 in Fulham, 29 in Wandsworth, 27 in Hackney, 24 in Lambeth, and 20 in St. Pancras and in Poplar. Of the 105 cases of cerebro-spinal meningitis, 13 belonged to Islington, 11 to Stepney, 8 to Southwark, and 7 each to Paddington, Hackney, and Lambeth; and of the 132 cases notified as poliomyelitis 12 belonged to Stepney, 11 to Islington, 11 to Camberwell, 9 to Lambeth, and 8 to Hackney.

The mortality figures in the table relate to the deaths of persons actually belonging to the several boroughs and are obtained by distributing the deaths in institutions among the boroughs in which the deceased persons had previously resided; the death-rates from all causes are further corrected for variations in the sex and age constitution of the populations. During last year the deaths of 61,101 persons belonging to London were registered, equal to a death-rate of 14·3 per 1000, the rates in the three preceding years being 14·6, 13·3, and 15 8 per 1000. Among the several boroughs the lowest death-rates last year were 10·8 in Wandsworth and in Lewisham, 11·1 in Hampstead, 12·4 in Woolwich, and 12·6 in Stoke Newington and in Hackney; the highest rates were 16·9 in Poplar, 17·2 in Bermondsey, 17·5 in Southwark, 19·0 in Shoreditch, and 19·4 in Finsbury. The 61,101 deaths from all causes included 4869, which were referred to the principal infectious diseases; of these, 1 resulted from small-pox, 1799 from measles, 159 from scarlet fever, 452 from diphtheria, 970 from whooping-cough, 117 from enteric fever, and 1371 from diarrhœa and enteritis among children under 2 years of age. The death-rates from these diseases in the aggregate ranged from 0·2 in Stoke Newington, 0·4 in Hampstead, and 0·6 in Kensington, in Hackney, and in Lewisham, to 1·5 in Bethnal Green, 1·7 in Stepney, in Poplar, and in Southwark, and 2·6 in Finsbury and in Shoreditch. The death from small-pox belonged to Woolwich. The 1799 fatal cases of measles were 223 below the corrected average number for the five preceding years; the greatest proportional mortality from this disease occurred in Finsbury, Shoreditch, Bethnal Green, Stepney, Poplar, Southwark, and Bermondsey. The 159 deaths from scarlet fever were 229 fewer than the corrected average number; this disease was proportionally most fatal in St. Marylebone, Finsbury, Bermondsey, Deptford, and Greenwich. The 452 fatal cases of diphtheria were 187 below the corrected average number; the highest death-rates from this disease were recorded in Hampstead, Holborn, Finsbury, Shoreditch, Greenwich, Lewisham, and Woolwich. The 970 deaths from whooping-cough were 318 less than the corrected average number; this disease was proportionally most fatal in Fulham, Finsbury, Shoreditch, Stepney, Poplar, Bermondsey, and Greenwich. The 117 fatal cases of enteric fewer showed a decline of 63 from the corrected average number; the greatest proportional mortality from this disease was recorded in Fulham, St. Marylebone, Shoreditch, Poplar, Bermondsey, Lambeth, and Lewisham. Diarrhœa and enteritis among children under two years of age were proportionally most fatal in Finsbury, Shoreditch, Stepney, Southwark, and Bermondsey. In conclusion, it may be stated that the aggregate mortality in London last year from the principal infectious diseases, excluding diarrhœa, was 22 per cent. below the average.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE undermentioned Acting Surgeons have been confirmed in the rank of Surgeon in His Majesty's Fleet:—Albert Edward Malone, Hamlet Mark Whelan, Robert Francis Preston Cory, Henry St. Clair Colson, George Albert Finegan, John Timothy Donal Sullivan Higgins, Jackson Graham Boal, Frederick St. Barbe Wickham, and Sidney Punch (dated Oct. 4th, 1912).

The following appointments have been notified:—Surgeons-General: A. J. J. Johnston to the *Pembroke*, additional, for Chatham Hospital, and to the Chatham Hospital; and A. W. May to the *President*, additional, for service at the Admiralty Medical Department.

ROYAL ARMY MEDICAL CORPS.

Frederick Edward Bissell, late Captain, Royal Army Medical Corps Special Reserve, to be Captain (dated April 16th, 1913).

Surgeon General H G Hathaway has taken up duty as Deputy Director of Medical Services to the Eighth (Lucknow) Division of the Southern Army

Colonel R J Geddes, D S O, has been placed under orders to return home from India on appointment as Assistant Director of Medical Services

Lieutenant Colonel E Eckersley has been selected for appointment to command the Military Hospital at Delhi *Lieutenant Colonel C W R Healey has* been granted eight months' leave of absence home from India Lieutenant Colonel J Thomson has been appointed for duty at Queen Alexandra's Military Hospital Lieutenant Colonel D M O Callaghan has been appointed to hold charge of the Military Hospital at Hilsea

Major W L Bennett has arrived home for duty from Bermuda Major E. A Bourke, on arrival home from Capetown, has been appointed to the Western Command Major A O Adderley has been transferred from the Military Hospital at Harrismith to Wynberg Major G J Stoney Archer has joined for duty at the Military Hospital, Cosham Major B R Dennis has been appointed to the London District Major A R O Flaherty has taken up duty at the Military Hospital, Ambala Cantonment Major W S Crosthwait has arrived in India for a tour of service Major E McDonnell has been appointed for duty to the Eastern Command Major S G Butler has been appointed to the Military Hospital at the Curragh The following Majors have been notified that they will be required for service abroad during the coming trooping season E E Powell G W Tate, C B Lawson H W H O Reilly, E H Condon, B W Longhurst, K B Barnett W Tabbits and W S Harrison

Captain G F Rudkin has arrived home on six months' leave of absence from India Captain C McQueen has been appointed *to the Aldershot Command* Captain A L Otway has been appointed Specialist Sanitary Officer at Portsmouth Captain P Farrant has embarked for a tour of service in the Sierra Leone Protectorate Captain N Dunbar Walker has taken up duty at the Military Hospital, Quetta Cantonment Captain W D C Kelly has embarked *for South Africa* Captain A E B Wood has been transferred from the Military Hospital at Hong Kong to Tientsin Captain D G Carmichael has taken up duty at Glencorse Captain G E Cathcart has embarked for a tour of foreign service Captain A S Littlejohns has been appointed to the Irish Command Captain R D O Connor has been transferred from the Military Hospital at Lahore to Multan Cantonment Captain A E Irvine has been appointed to the Belfast District Captain C M Ingoldby has been transferred from the Military Hospital at Cork to Kilkenny for duty Captain D P Johnstone has taken up duty at the Military Hospital Jhansi Captain N E Dunkerton has been appointed to the Aldershot Command Captain F McCammon has been appointed for duty in the Dublin District Captain R O Priest has been transferred from the Military Hospital at *Lebong to Allahabad Cantonment for duty Captain C H* Turner has joined at Dublin Captain J W L Scott has been appointed to the Royal Victoria Hospital at Netley Captain L Cotterill has been placed under orders for service abroad Captain C G Sherlock has been transferred from Bakloh Cantonment to the Military Hospital at Lahore for duty Captain E C Whitehead has joined the Military Hospital at Glasgow Captain G R Painton has joined for duty at Colchester

Lieutenant G Wilson has embarked for a tour of service in India Lieutenant B Biggar has left London for duty in Egypt Lieutenant G H Dive has been transferred from Tientsin to Peking for duty with the British Section of the Legation Guard Lieutenant A G J MacIllwaine has been transferred from Aldershot to Deepcut for duty at the Section Hospital Lieutenant E L Fyffe has left the Military Hospital at Cork and taken up duty at Poona Lieutenant C H Harold has been placed on special duty at Rawal Pindi Cantonment for a course of instruction in Indian sanitation and preventive medicine Lieutenant F G S Cane and Lieutenant F A Robinson have embarked for a tour of service in India Lieutenant R F Bridges has been transferred from the Second (Rawal Pindi) Division to the First (Peshawar) Division for duty at the Headquarters Military Hospital Lieutenant J M Elliott has been transferred from the Military Hospital at Portsmouth to Hilsea The following Lieutenants will be required for service abroad during the coming trooping season B H H Spence, W B Laird, R Davidson, H S Blackmore J M Elliott, F R B Skrimshire D W Bruce, T E Osmond, R T Vivian, E G H Cowen, L Buckley, and W L Webster

INDIAN MEDICAL SERVICE

*Lieutenant Colonel C R M Green Bengal Establishment, has been selected for the advanced rate of pay under Article 7 of the Royal Warrant Lieutenant Colonel J R Adie has been granted six months' extension of his leave of absence home from India on medical certificate Lieutenant Colonel Sir R Havelock Charles, G C V O, has been granted the temporary rank of Surgeon General, while employed as President of the Standing Medical Board at the India Office Lieutenant Colonel H E Banatvala has been selected to officiate as Inspector General of Civil Hospitals in the Central Provinces during the absence on eight months' combined leave home from India of Colonel G W P Dennys

Major A Fenton has been selected for appointment as officiating First class Civil Surgeon under the Government of Burma during the absence on leave of Lieutenant Colonel R H Castor Major S P James has taken up special duty under the Government of Ceylon for a period of one year Major W J Niblock has arrived home on leave of absence from India Major E R Rost and Major E L Ward have been awarded the Kaisar i Hind medal of the First Class for public services in India Major H J Walton has been selected for appointment as Professor of Pathology on the staff of King George s Medical College at Lucknow Major H W Illius has been selected for appointment as Civil Surgeon at Rae Bareli Major C B Prall has taken up duty at Lucknow as Superintendent of the Central Prison Major E J Morgan on return from leave, has been selected for appointment as Civil Surgeon at Sitapur Major J W Lethbridge has been granted 15 months' leave of absence home from India by the Foreign Department Major J Stephenson Principal of the Government College at Lahore has been appointed a Fellow of the Punjab University Major V G Drake Brockman, Agency Surgeon of the Second Class has been selected for appointment as Civil Surgeon at Dera Ismail Khan

Captain W S McGillivray has been selected for appointment as Specialist in Otology Larnygology and Rhinology Captain A G Tresidder *has taken up the appointment* of Substantive Medical Officer to the 87th Regiment of Punjabis Captain A F J *Lister has been selected for appointment* as Professor of Physiology at King George s Medical College Lucknow Captain P M Rennie has been granted an extension of leave of absence home from India for five months for study purposes Captain F W Sumner has been selected for appointment as Civil Surgeon at Farrukhabad Captain J McPherson has joined the Mewar Bhil Corps as Medical Officer under the Foreign Department Captain F S Smith has been selected for appointment as Substantive Medical Officer to the 120th Rajputana Infantry Captain F N White has been selected for appointment as officiating Secretary to the Director General of the Indian Medical Service in the Sanitary Branch during the absence of Major A G McKendrick Captain F C Fraser has taken up temporary duty in connexion with plague prevention under the Government of Madras Presidency

TERRITORIAL FORCE

Royal Army Medical Corps

2nd East Lancashire Field Ambulance Royal Army Medical Corps Quartermaster and Honorary Lieutenant John Walter Graham Steell from the 1st East Lancashire Field Ambulance Royal Army Medical Corps to be Transport Officer with the honorary rank of Lieutenant (dated March 27th 1913)

Attached to Units other than Medical Units —Captain Frederic W Kendle to be Major (dated Feb 21st 1913) Lieutenant George B Gill to be Captain (dated *Feb 25th* 1913) Major James A Wilson resigns his commission and is granted permission to retain his rank and to wear the prescribed uniform (dated April 16th 1913) Major William Ernest Miles from the 3rd (City of London) Field Ambulance Royal Army Medical Corps, to be Major (dated March 13th, 1913)

COLONIAL MEDICAL SERVICES

Colonies and Protectorates —Dr W W Martin, Dr J W Adams, and Dr J London have been selected for appointment as Medical Officers in the Straits Settlements; Mr. J. M. G. Ewing has been selected for appointment as a District Medical Officer, St. Vincent; Mr. W. N. A. Paley has been selected for appointment as a Medical Officer, Fiji; Mr. W. S. Coffey has been selected for appointment as a Medical Officer in the Federated Malay States; and Dr. Orme has been seconded from the Federated Malay States Service to act as Principal Medical Officer, British North Borneo.

EXAMINATION FOR APPOINTMENTS AS ACTING SURGEONS IN THE ROYAL NAVY MEDICAL SERVICE.

At the examination for the Naval Medical Service held, on April 7th, 8th, 9th, and 10th, 1913, 14 candidates were successful. The maximum number of marks obtainable was 2400.

JOURNAL OF THE ROYAL ARMY MEDICAL CORPS.

The first article in the April number of the *Journal of the Royal Army Medical Corps* occupies 36 pages of the issue, and is a very interesting and concise account of Dark-ground Illumination in Microscopical Work, by Maurice A. Ainslie, R.N., Naval Instructor to H.M.S. *Britannia*. The method here explained, though not new, has received considerable attention in recent years, especially in the study of bacteria in their living state, and the author devotes his opening remarks to an historical summary of dark-ground illumination and the use of the condenser. It should be mentioned that, although the methods of Seidentopf and Zigsmondy are, strictly speaking, a form of dark-ground illumination, the author excludes these methods as being outside the scope of the present article. In successive little chapters he deals with the refractive index and numerical aperture, the various optical systems employed for dark-ground illumination, stops, objectives, eyepieces, and illuminants, and gives practical instructions for the adjustment of apparatus. The article is illustrated by some very clear diagrams and will be appreciated by those who wish to have a clear insight into the principles of the subject with which it deals. An address given to medical officers and assistant surgeons at Peshawar on medical tactics at the beginning of the year by Colonel R. H. Firth, included in this issue, is intended as a guide as to what officers should or should not do if they find themselves in charge of medical unit staff rides, and the author emphasises the need of keeping simple and frequent notes of the position and condition of units. An article by G. Fahey, late 88th Connaught Rangers, whose opinions and suggestions with regard to the hygiene of the soldier formed an interesting feature of recent issues of the journal, is worthy of thoughtful perusal, the subject of the paper being "Regimental Stretcher-Bearers."

THE ROYAL ARMY MEDICAL COLLEGE.

The Secretary of State for War will present the prizes at the Royal Army Medical College, Grosvenor-road, S.W., on the conclusion of the 105th session on April 29th, at 4 P.M.

THE IMPERIAL SERVICES EXHIBITION, EARL'S COURT, S.W.

The committee of the Royal Artillery Mess have lent an imposing marble statue, entitled "Armed Science," to the Imperial Services Exhibition, which will open at Earl's Court on May 31st, and the National Lifeboat Institution will show a full-sized lifeboat, together with various other appropriate exhibits. The general committee of the Imperial Services Exhibition are offering prizes for members of the British Red Cross Society to be competed for by the Women's and Men's Detachments of the Voluntary Aid Organisation throughout the country. The finals and semi-finals of the competition will be held at the exhibition, and will last a week. The Red Cross Society are providing an interesting exhibit in the grounds, where practical demonstrations of ambulance work will be given. The West African Force will also have an exhibit. It will consist of a representation of a camp with models of the various types of troops employed in West Africa. In order to provide for the comfort of the large number of ex-soldiers and sailors who have been employed in preparing the exhibition, arrangements have been made for a canteen and recreation room to be used by the ex-service men.

ROYAL NAVAL MEDICAL SUPPLEMENTAL FUND.

At the quarterly meeting of the directors of the Naval Medical Supplemental Fund, held on April 8th, Sir J. N. Dick, K.C.B., in the chair, the sum of £70 was distributed among the several applicants.

THE ANTARCTIC DISASTER.

Surgeon E. Atkinson, R.N., arrived at Plymouth on April 15th on board the New Zealand Shipping Company's steamer *Remuera*, accompanied by Mrs. Wilson, widow of Dr. Wilson.

Correspondence.

"Audi alteram partem."

A QUESTION OF CONTRACTS.

To the Editor of THE LANCET.

SIR,—The Scottish Commissioners under the National Insurance Act called for Friday last at Edinburgh a conference on the problem of the migrant and the summer visitor. Invitations were issued to Medical Committees to send representatives, and to clerks to Insurance Committees and others. On entering the room delegates were handed eight typewritten foolscap sheets dealing with the system proposed. After a speech by the chairman, Dr. McPhail was called upon to explain the proposals. Briefly, it was proposed to form a general pool and to pay by fee for service rendered. To form the pool it was proposed to deduct so much from the amount (7*s.*) payable to doctors for each insured per annum.

Two methods were offered: (*a*) A deduction of 1*d.* per quarter for each insured; this has the merit of simplicity at least. (*b*) The pool was to be obtained by deductions based on a so-called "illness value." Dr. McPhail referred the explanation of this system to Dr. Currie, the "onlie begetter" thereof. It was recommended as being fairer in its incidence, but it was obviously too complicated to be grasped by the meeting even after explanations.

From the point of view of the medical profession the important features were (1) payment by fee for migrants and visitors; (2) fee fund to be obtained by deductions from the 7*s.* payable to each doctor for every insured on his list. The chairman was promptly asked the following question: "Doctors having already signed a contract agreeing to serve under published Regulations, have the Commissioners any legal power or right to make any deductions from the 7*s.*?"

The chairman spoke at large, but would not answer the question. Dr. McPhail followed, and also avoided giving an answer, and then, as this was firmly requested, Mr. Fraser, the legal member, rose. At first he refused to commit himself, but in the end acknowledged that the Commissioners had no legal power to make these deductions. The point was raised, not in any way for the purpose of wrecking any reasonable scheme to overcome a pressing difficulty, but to establish at once the fact that every doctor's agreement with an Insurance Committee was a contract binding on both parties and only to be varied by agreement of both parties. The Commissioners' scheme must shortly be placed before the Medical Committees, and it was obvious at the conference that every effort would be made to rush it through.

You, Sir, will therefore be doing a great service to Medical Committees by giving wide publicity to the fact that the Commissioners have publicly acknowledged that they have no legal right to vary the Regulations this year without the consent of those who have signed their contracts. The Commissioners' scheme is a reasonable attempt to overcome a pressing difficulty—though by no means perfect—for one thing, no attempt had been made to make arrangements for those moving about within the limits of any single area—e.g., from one side of Perthshire to another. The amount of deduction, the method of deduction to form a pool for payment, the checks upon fraud, and the fees for service rendered are all matters for friendly discussion, but I think you will agree that more important is the sacredness of a contract. I am, Sir, yours faithfully,

HORACE C. COLMAN, M.D. Edin.

Broughty Ferry, Forfarshire, April 13th, 1913.

IODOFORM INJECTIONS IN PULMONARY TUBERCULOSIS.

To the Editor of THE LANCET.

SIRS,—I read with interest Dr. E. Curtin's letter in THE LANCET of April 12th. He either omits to mention or has [illegible] to the pati [illegible] stress has [illegible] ers. I venture to offer a few remarks bearing directly on this aspect of the subject.

During the past few months I have administered iodoform dissolved in ether, plus a small percentage of "paroleine," intravenously to 54 patients (32 men, 20 women, and 2 children) in different stages of pulmonary tuberculosis, the total number of injections being 1800 odd. If the technique be carefully and correctly observed the whole matter should be absolutely painless. The patient usually experiences a transient fit of coughing of from 10 to 20 seconds' duration.

In but one case in the series was the coughing excessive; this unpleasant, and in some cases possibly dangerous, symptom was obviated by only allowing the fluid to enter the blood stream minim by minim, with an appreciable interval between each drop. In two other cases slight hæmor- [illegible] *post hoc* or *propter hoc* [illegible] hen the sputum became [illegible] and no return of the hæmorrhage took place. Up to the time of writing no patient has objected to the treatment on the grounds of personal discomfort.

I purposely refrain at present from drawing any conclusions as to therapeutic value, only a limited number of patients having completed the treatment.

I am, Sir, yours faithfully,

FRANK CROSBIE, M.D. Dub. Univ.

The Hospital, Newcastle, co. Wicklow, April 14th, 1913.

TUBERCULOSIS OFFICERS, SCHOOL MEDICAL OFFICERS, AND THE MEDICAL OFFICERS OF HEALTH (SUPERANNUATION BILL).

To the Editor of THE LANCET.

SIR,—I should like to thank Dr. Alexander Graham for his timely letter in THE LANCET of April 12th, and to support his appeal for the urgent need of an amendment to the Medical Officers of Health (Superannuation) Bill, so that under "medical officers of health" school medical officers and tuberculosis officers will be included as well. I wish to specially urge the inclusion of tuberculosis officers for the following reasons:—

1. They are whole-time medical officers, and as such are unable to augment their income by doing other work. A part-time medical officer of health is included in the Bill. He usually has a large and lucrative general practice, and is in a better financial position than the tuberculosis officer.

2. Better men will undoubtedly apply for these posts if there is an assured superannuation scheme attached to them. The advantage to the community is obvious.

3. If medical officers of health are singled out for the superannuation scheme and tuberculosis officers excluded, the latter will feel under a grievance which cannot favourably affect the harmonious relations between them which are necessary in the public interest.

4. It should be easy and practical to include tuberculosis officers because all these appointments are quite new, and, therefore, payments can be made in every case from the commencement of the appointment.

I trust every tuberculosis officer will support Dr. Graham in this important matter by writing to him as he suggests. I am, Sir, yours faithfully,

G. LISSANT COX,

Tuberculosis Officer for the County Palatine of Lancaster.

County Offices Preston, April 12th, 1913.

THE INDIVIDUAL TREATMENT OF DIABETES.

To the Editor of THE LANCET.

SIR,—The celebrated exclamation, "Vous êtes orfèvre, Monsieur Josse," from *L'Amour Médecin*, came to my lips after reading Dr. Arany's able paper on "The Individual Treatment of Diabetes."[1] When he writes that our duty is to accommodate our treatment to each individual case, I feel sorry for the poor opinion he seems to have of the pre-Arany era penny-in-the-slot treatment we must have evidently indulged in. But when he concludes that as regards dietary conditions the Austrian spas are "quite reliable" (*parbleu!*), that the German ones are "not quite so good," and that in the French resort "the patient is almost left at large," I really feel I cannot let such a drastic statement pass unchallenged.

If Dr. Arany had taken the trouble to come to Vichy and see for himself—as so many British doctors do to whose evidence I appeal—he would know that for several years the diet question has been settled in all leading Vichy hotels, to say nothing of the specialised *maisons de régime.* In every one of these places he will find a special cuisine for cases of diabetes and another one for cases of gastro-hepatic disorders. Our patients are individually directed as regards their diet, and if the system is not "quite reliable," I would feel grateful to Dr. Arany if he kindly pointed out the fault. Or are we to admit that our patients are at large while we French doctors are mentally "*au maillot*," and that, to reverse the balance, Carlsbad patients are stringently "*caporalisés*," while their doctors, as seems to me, are at large? I am, Sir, yours faithfully,

GUSTAVE MONOD,

M.D. Paris, L.R.C.P. Lond., M.R.C.S. Eng.

Vichy, April 6th, 1913.

42 YEARS OF CONTRACT SERVICE.

To the Editor of THE LANCET.

SIR,—The position of "parish doctor" may not be a very lofty one in our profession, and is not thought much of either by some practitioners or by the British public. The title is unfortunate and the pay is small. But the office is an honourable one and important to the health of the general community, for complaints are apt to be caught from the pauper, even by the rich and mighty in the land.

In 1871 I succeeded Mr. B. Hands as parish doctor of Hornsey, where he had been the sole medical resident for 47 years. He was a contemporary of my own father at St. Bart.'s Hospital, both being apprenticed to John Abernethy. Now, retiring after 42 years' service, I am fortunate enough to be able to say that I have not had a single official complaint as to my treatment of the poor. My salary has remained the same throughout, though the population of the district has increased from below 20,000 to about 90,000. On the whole I have enjoyed the position, more especially the post of public vaccinator, in which I have preached the common sense of the procedure, while I can honestly say that I have never seen any ill-effects from it.—I am, Sir, yours faithfully,

F ORTON,

Surgeon-Lieutenant Colonel, V.D. (retired).

Crouch End, Hornsey, N., April 6th, 1913.

** We congratulate our correspondent and the authority with whom he has worked upon this long and useful record.—ED. L.

THE POSITION OF ASSISTANT MEDICAL OFFICERS IN ASYLUMS.

To the Editor of THE LANCET.

SIR,—I have read with some interest and considerable astonishment the letter of your correspondent "Reform" in THE LANCET of April 12th. [illegible] regarding the position and work [illegible] in asylums appear to be much [illegible] tions may exist in some asylums, but they certainly do not in all. My asylum experience extends over 20 years, and in no case have I found conditions prevailing such as described by your correspondent.

---

[1] THE LANCET, March 29th, 1913, p 884.

In every asylum I have been connected with each medical officer has had his own section and was responsible entirely for both the medical and surgical treatment of the patients under his care, and only in very rare instances has any outside surgical assistance been requisitioned; indeed, many operations are performed by the medical officers of asylums which the average general practitioner would not undertake. Several asylums have well-equipped pathological laboratories, and the assistant medical officers are encouraged to undertake scientific research. An essential feature of the assistant medical officer's work is to study the mental peculiarities of his patients, and to note the influence of mind on body. This must be of great assistance to him if eventually he decided to take up general practice. Moreover, his work in asylums trains him to recognise and treat early symptoms of mental aberration in his patients. As to the promotion of assistant medical officers, there is no doubt a certain amount of luck, but, as in other branches of the profession, steady and conscientious work usually meets with recognition.

I do not agree with your correspondent regarding the lack of skilled nursing in asylums. I am pleased to say I have met many excellent sick nurses, both male and female, and the course of study required for the nursing certificate of the Medico-Psychological Association is both thorough and comprehensive. In addition to the ordinary training in nursing, instruction in massage is now given in some asylums. I would point out to "Reform" that a large part of the training of nurses in asylums falls to the lot of the assistant medical officer, and that a keen medical officer usually means keen and competent nurses.

I am, Sir, yours faithfully,
F. R. P. TAYLOR.

East Sussex County Asylum, Hellingly, April 15th, 1913.

PROFESSIONAL FEES IN BANKRUPTCY.

To the Editor of THE LANCET.

SIR,—There is at present before Standing Committee B of this House a measure entitled "A Bill to Amend the Law with Respect to Bankruptcy and Deeds of Arrangement."

As the law now exists, under the preferential payment in the Bankruptcy Act of 1888, there shall be paid in priority to all other debts certain rents, rates, salaries or wages of clerks, servants, workmen, &c. To these classes entitled to priority I sought to add, without success, the fees due to professional nurses. I instanced cases where, after prolonged attendance on a patient, they were obliged to accept a compensation of 2*s.* in the £, the same as an ordinary trade debtor. I am confident that it only requires public attention to be drawn to the gross injustice possible to a noble profession under the existing law to have it altered. If those interested or sympathetic will only speak out between now and the report stage of the Bill I have no doubt the necessary amendment of the law would appeal to the sense of justice of all parties in the House.

In my opinion, the medical profession have also a strong claim for an amendment in the existing law under which, as it is at present, their fees only rank as ordinary creditors. I think that for some considerable time before a receiving order is granted, their fees should rank with those entitled to priority of treatment.

I am, Sir, yours faithfully,

House of Commons, April 15th, 1913. PATRICK WHITE.

"PSEUDO-BABINSKI" SIGN IN ANKYLOSIS.

To the Editor of THE LANCET.

SIR,—The impression has always been received that the Babinski extensor response to stimulation of the sole of the foot was pathognomonic of diseases of the descending pyramidal tract, the one exception being the post-epileptic response. In the phthisis wards at the Leeds City Hospitals there was recently a patient who had an ankylosed knee-joint due to old tuberculous disease. On testing this man's reflexes we discovered that he gave a "Babinski" with the toe of the ankylosed limb. Dr. H. de C. Woodcock, visiting physician to the tuberculous wards, who was going round with me, stated that he had, with Dr. W. Craig Stewart, of Leeds, seen another similar case of pseudo-Babinski following ankylosis of the knee-joint, and that he had brought the phenomenon to the notice of Dr. Edwin Bramwell, who considered that the explanation might be found in irregular tonicity in the extensor tendons and muscles of the foot, and that on stimulation the extensor tendons contracted more slowly than in the normal condition. Dr. Woodcock had also sought the opinion of the late Dr. G. A. Gibson, of Edinburgh, and he was inclined to think the explanation would be found in a condition of abnormal irritation in the nerve centres set up by the ankylosis. Dr. Purves Stewart hints at the condition in one page of his book, but I do not remember any reference in other authors. I am, Sir, yours faithfully,

JAMES A. M. CLARK, M.B., Ch.B. Aberd.,
Senior Resident Medical Officer, City Hospitals,
April 14th, 1913. Seacroft, Leeds.

INFANT MANAGEMENT.

To the Editor of THE LANCET.

SIR,—I must admit that when I read a few months ago the brief notice in your columns of Dr. E. M. Brockbank's book on "Children: their Care and Management" I did not feel encouraged to read it myself, and still less to recommend it to my patients. But, as it happened, circumstances brought the book into my hands, and in justice to the author I think I should send you my opinion of it, based on a practical application of its teaching to the needs of my own family. I opened its pages with no feeling of prejudice in its favour. But I quickly found that it contained much that would be helpful to the young mother overwhelmed with the task of bringing up her first baby, and very little that need conflict with the instructions of the up-to-date medical attendant. I disagree, as you do, with certain of Dr. Brockbank's precepts, but on the whole I think his book compares very favourably with the many other books written with a similar intention which I have studied. It seems to me extremely practical and lucid, quite free from mawkish sentiment, and inspired by a sympathetic insight into the difficulties of infant management. The ideal popular work on this subject has yet to be written, but in the meantime I would rather place Dr. Brockbank's book in the hands of an inexperienced but educated mother than any other I know of. I need scarcely add that I am personally unacquainted with the author. I am, Sir, yours faithfully,
M.B.

April 14th, 1913.

⁂ We have pleasure in publishing this unsolicited testimonial.—ED. L.

INSANITY AND DIVORCE.

To the Editor of THE LANCET.

SIR,—Dr. John Batty Tuke, jun., in his letter under the above heading, appears to suggest that the Royal Commission on Divorce has recommended that "after a certain number of years' detention in an asylum insanity should form a plea for divorce." I do not know of any "proposal" relating to insanity as a ground for divorce that need be considered other than that of the Royal Commission, which was not as Dr. Batty Tuke summarises it. The report recommended as a ground of divorce "incurable insanity after five years' confinement." It further recommended as a safeguard with regard to the proof of incurability the appointment of two experts whose duty it would be to examine and report to the court. There might have been a danger of an unjust divorce in the case described by Dr. Batty Tuke if he is satisfied that he himself would have unhesitatingly pronounced his patient to be incurable at the end of the first five years of her confinement, and if, in his opinion, the two official experts would have been unanimous in pronouncing her incurable after hearing his narrative of steady and uninterrupted improvement. It may be noticed that in any case she only missed by three years the exemption proposed by the Royal Commission for married women over 50 years of age. I am, Sir, yours faithfully,
E. A. A.

April 14th, 1913.

MEDICAL PRACTICE UNDER THE INSURANCE ACT.

(BY OUR SPECIAL COMMISSIONER.)

(Continued from p. 990.)

VI.—QUALIFIED APPROVAL OF THE ACT AT DUMFRIES.

How the Act was Accepted.

IN Section 80 (4) of the National Insurance Act special mention is made of the burgh of Dumfries and the police burgh of Maxwelltown. Dumfries is a Royal borough; it has an ancient history and attracts many visitors who come to see the well preserved haunts of Scotland's great poet, Robert Burns, though its actual population only amounts to 16,061. But if the Royal borough of Dumfries is joined to the police burgh of Maxwelltown the total population of the two is 22,261. This junction is essential under the National Insurance Act, as a burgh, for the purposes of the Act, must have a population of not less than 20,000 inhabitants. So, in speaking of Dumfries in this article it must be understood that Maxwelltown is included in the term, and indeed, there is only a river of no great width between them.

Of the population in these joint burghs some 7000 are insured persons, and in the early days of March 6700 had selected their medical attendants. All the practitioners of Dumfries, except a specialist for diseases of the ear and throat, are on the panel. The panel consists of eight practitioners and three assistants, so that there is more medical service obtainable than is needed for panel work only. At first the medical men were all opposed to the Act and were resolved to have nothing to do with it. But these bold resolves cooled down when it was discovered that at Glasgow, even before Christmas, medical practitioners were willing to go on the panel, and that in Ayrshire and Stirlingshire all went in. The Dumfries Insurance Committee could have imported medical men from Glasgow and could have offered a sufficient income to induce five or six to come. This would have ruined all the newly established practitioners and seriously injured the others. Indeed, half the population would have been lost so far as the medical practice of the established practitioners is concerned. Then, looking closely into the matter, the medical profession began to hold that the terms under the Insurance Act were not so bad, and that, indeed, in some respects they offered advantages over pre-existing arrangements. In any case, this much can be said for the attitude of the Dumfries practitioners: it does not seem to have been influenced by political preferences. A practitioner known to be a convinced Conservative nevertheless emphatically approved of the Act, while a large proportion of Liberals were as thorough in their opposition. One thing all agree the Act has done. Here, as elsewhere, it has brought the profession much closer together.

All Contract Work Outside the Act Abolished.

Before the Act was working there existed at Dumfries branches of several Friendly Societies, such as the Foresters, the Oddfellows, and the Free Gardeners. Four practitioners held appointments from these various bodies. When, however, the Insurance Bill was introduced all the medical men of Dumfries held a meeting to discuss the situation. It was then decided that the first thing to be done was to give up all such contract work and not to accept any other similar appointment. It is something to be able to relate that this agreement has been faithfully kept. To-day at Dumfries there is no other contract medical work being done except what is being done under the Insurance Act. The practitioners have shown such unanimity throughout “ ‘

to hear more than one among tl

better now ”, but they may still

showing the strength of union

may occur with regard to the dependents on insured persons.

The Question of Mileage.

Undoubtedly a good many paying patients have now become insured persons, and the difficulty is to know what policy to follow so as not to lose still more of those who remain as private clients. This problem presents itself in regard to attendance upon domestic servants. There are many small landed estates round about Dumfries held by well-to-do families who are not extremely wealthy. The servants of these families are now insured persons, and if the family practitioner is not on the panel then the servant would introduce some other practitioner into the household. This means that the town practitioner puts his name on one or more neighbouring country panels where the estates of his best patients are situated. But having done so, he is apt to be called out of town, not only to attend his well-to-do clients and their servants, but anyone else who, seeing his name on the panel, has asked to be put on his list. It is not always prudent to refuse such tribute to popularity, and it is easy to imagine circumstances where to do so would not be right. If an allowance for mileage could be obtained this sort of thing would lose its terrors. But the only mileage allowed is calculated from the house of the medical practitioner who is nearest to the patient and on the panel, and the distance must exceed three miles. Thus a Dumfries practitioner explained to me he was physician to a family living at a distance of nearly seven miles from his house. After going four miles he passed the house of another panel doctor. This was the nearest doctor to his patient's house, and the distance was over two miles; so as the patient is not more than three miles from the nearest panel doctor no mileage is allowed, yet the practitioner who actually attends him has to travel just upon seven miles each way. It is true that a town doctor cannot be coerced into accepting patients living more than three miles from the town, but he is sometimes obliged to do so at Dumfries, for the best patients live on estates at considerable distances from the town. Then not only do the town doctors go out in the country districts, but some inhabitants of rural districts come and seek advice from the town physicians. It is difficult to prevent a good deal of overlapping. The country doctors have, however, one great advantage. They have no local nucleus for contract practice, so it would be absolutely useless for anyone to attempt to import practitioners to compete against them. There would be nothing to offer any imported man that would constitute a *sufficient inducement*. If the rural practitioner could obtain a more liberal mileage allowance his principal cause for complaining against the Act would be gone was the opinion prevailing at Dumfries.

Details of Practice.

Addressing myself to one of the leading practitioners in Dumfries he at once declared that he was fairly satisfied with the results under the Act. It is true he never had much club practice, but panel practice was an improvement by reason of its better and more severe regulations. He was not now so often troubled on a Sunday, and on weekdays the patients observed more strictly the consultation hours. This regulating of practice was in itself a great benefit; it was a fortunate accompaniment of the Act coming into force, as both his private and contract practice had increased since that date. It was not yet possible to tell how many of his former private patients had become contract patients under the Act; but several insured persons had declared to him that they would continue to pay fees as usual. Two such cases which he quoted were of persons who were insured because their regular income was below the income tax limit, but who generally received a good deal more money in an irregular way, and preferred to pay for the conveniences of private attendance. This practitioner calculated he had more than 400 insured persons on his list living within a mile of his house. During the first fortnight he received 37 visits at his surgery and had to pay 13 visits to patients in their own homes. These included some trivial cases such as a cut hand, a slight indigestion, a pimple, a gumboil, but there was an urgent case of appendicitis and a severe example of influenza. This was varied by a clerk who came because he had wax in his ear and a shop girl because her nose was too red. A complication arose in regard to a girl with a tuberculous joint, which may be mentioned as illustrative of a procedure that may become common. Formerly this patient was attended on purely charitable grounds. Now her family have paid all her insurance fees and she presents herself on the footing of an employed person. It is very doubtful whether she has any employment. Probably the family pays the fees of a fictitious employer. Other practitioners related that this was also the case with a few of their patients. It is a question, however, whether such manœuvres do any harm. They were not contemplated by the Act, but if a family pays instead of an employer in any case a payment is effected, whereas formerly the patient was attended purely for charity. Of course, the question of hospital treatment arises here. Many patients formerly treated on charitable grounds at the hospital will now be necessarily relegated to the medical men on the panels. Apart from the town patients, the first practitioner I saw had 50 names of persons who live in the country. Of these, six were ill during the first fortnight; but when he went out to see them he could generally contrive to make his visits in the course of a round in which he would also be visiting some paying patients. As yet, said this practitioner, there had been no hardships, except the excessive clerical work; that, he hoped, would be simplified, and in any case the worst was over.

The Allurements of Sick Pay.

The next two practitioners on whom I called were specially concerned about malingering. "The Act will do good, there can be no doubt about that," said the first; "but it does encourage malingering." Many persons got cards to which they were not entitled, he pointed out; and it is astonishing how many people had found out, since the Act came into force, that they could not do any more work. Even youths had discovered how to provoke an indigestion so as to get a holiday. He had half a mind to spoil the fun by prescribing a quantity of blisters. From this and other causes the members of the profession had a great deal more work to do than formerly, and for his part he could not tell whether it would pay better. They must wait until the summer experiences could be summed up before they could speak definitely; undoubtedly the work was hard, very hard now. The experience of both these gentlemen bore out what had been anticipated while the Bill was being discussed in Parliament and in the columns of THE LANCET. Before the Act those who were insured obtained from the Foresters and such societies less sick pay. They never got more than 9*s.* a week from their clubs, so they were more anxious to get back to work than they are now, when they may receive 10*s.* from an approved society under the Insurance Act and 9*s.* from another society. In these circumstances there was no need to hurry back to business. The next practitioner on whom I called went further than this. He knew of men who belonged to two Friendly Societies, so that when they were ill they got 9*s.* from the one, 9*s.* from the other, and 10*s.* insurance money, making 28*s.* a week, which was more than some of them could earn while in full work. Thus some men are literally living on their societies. There is, of course, this great difficulty that few men are absolute malingerers. Most of them really have a pain or a disability or an inconvenience, or truly believe that they have, but some of them make a serious affair of their trouble, and of course they are persuaded to take up this attitude by its pecuniary inducements. The medical adviser on his side is sorely tempted to sign the certificates quickly so as to secure the patient's prompt departure. Then it is most remarkable how rarely patients get well on a Thursday or Friday. It seems that the rounding off of a week is quite essential for an effective cure. The percentage of recoveries on a Sunday or Monday morning would be quite difficult to explain, if explanation were useful. But this was always the case with sick pay under the old club system, and must be regarded as a sort of accepted abuse. It cannot be prevented, but it might be well to watch those who belong to two societies besides being insured persons. Obviously if patients succeed in prolonging the duration of an illness, this means more work for their medical attendant, and a greater drain on the insurance funds. Thus I heard of a man who is a member of three societies and who is also an insured person under the Act. Every time he is incapacitated from work he wants four different certificates, and being only a labourer is better off when in receipt of all these benefits than when earning his usual small wage.

Effect of the Act on the Patent Medicine Trade.

At Dumfries, as at Carlisle, the officials of the Friendly Societies are no longer as ready as formerly to work gratuitously or for very small fees. The Foresters, for instance, had a sick steward who gave the money; it was done in a friendly manner among men banded together in a sort of brotherhood. But these men were amateurs, not trained accountants. On the other hand, large business insurance organisations employ only trained accountants, and they do not pay without formality. They are hard-and-fast business men, and the people do not like this, while acknowledging that the officials of the Friendly Societies were not such good managers. This is a big question affecting the whole country and on which much more will have to be said. Then there are a good many who are not fully employed, but are fully insured. For this and many other reasons the question of the ability of those who actually apply the Act is of far-reaching importance. At Dumfries the Prudential was early in the field, and gathered in many newly insured persons. A practitioner who has a large connexion among the Roman Catholic section of the population explained that there was the St. Andrew's Benefit Society to which rich and poor Roman Catholics subscribed, the latter so that they might get medical assistance and the former to help by their subscriptions. But this organisation was not locally strong enough to be recognised under the Act till it federated with other similar bodies in other parts of Scotland. Now that many members of this society are insured their medical officer testified to me that the work was much better regulated. In his experience he found that the insured persons carried out loyally the rules put down by the Insurance Commissioners, and were anxious not to cause unnecessary trouble. Well-paid artisans who paid a good bill nearly every year would now be lost, but there were others who ran up a bill for a year or two and then changed the medical adviser but never paid. These bad debts were now a melancholy memory of the past. These, the authors of bad debts, were all paying now insurance money. The incomes of the profession would undoubtedly increase, but so would the amount of work that they had to do. The practitioner would have more cash in hand—that was sure; whether the increase of income would be in proportion to the increased amount of work that has to be done was quite another matter. It was too soon to form an opinion, Certainly he had quite a number of patients who had told him they were ashamed to take medical benefits and were offering to pay the usual fees. There was one great good he anticipated from the Act; it struck a heavy blow at the trade in patent medicines. Many people who could not pay for medical advice read advertisements of patent medicines and drugged themselves. Now, instead of trusting to advertisements and spending what little money they could afford on the drugs advertised, they would consult their panel doctor. This meant more work for the profession, and the general increase of work had its evil side because it left no time for study. "Medicine was likely to come to a standstill." How many panel doctors were able to find time today to read a medical journal or book, and even when they held branch, divisional, or any other sort of meetings, they no longer talked medicine but insurance. In spite, however, of all these criticisms there was not the bitter feeling against the Act I have noticed elsewhere. Some were convinced that, on the whole, the Act was going to do good; and others were not sure that the evil it was likely to occasion would overbalance the good it would accomplish.

(To be continued.)

THE INTERNATIONAL CONGRESS ON PHYSIOTHERAPEUTICS.

(FROM OUR SPECIAL CORRESPONDENT.)

THE International Congress on Physiotherapeutics was opened in Berlin on March 26th. The inaugural meeting was held in the great hall of the Reichstag, Professor His being in the chair. The meeting was attended by the patron of the Congress, H.R.H. Prince August Wilhelm of Prussia. The number of foreign delegates was especially great. The British army medical department was represented by Director-General Sir W. Launcelot Gubbins and Major C. E. Pollock, R.A.M.C., the Royal College of Physicians by Dr. Archibald E. Garrod, and the Royal Society of Medicine by Dr. Reginald Morton and Mr. William Deane Butcher.

The PRESIDENT, in his inaugural address, said that physiotherapeutics were already highly developed in ancient times, especially during the Roman Empire, but that they had been neglected with the decrease of general culture in the early Middle Ages. In more recent times the study of anatomy, physiology, and pathology was the principal feature of medicine, and therapy was relegated somewhat to the background, and although certain physical methods continued to be cultivated by laymen, these methods were based upon mere empiricism; and experience without scientific research must naturally lead to uncritical proceedings. Medical science, however, had once more realised the great therapeutic value of physical agents. Only with reluctance did Science approach the methods of physiotherapeutics, but once having done so she had given them an irresistible impetus. There was scarcely one disease that could escape their influence. She found stupendous tasks in the struggle against tuberculosis and cancer, against infant mortality, and disturbance of growth. These methods dominated the therapeutics of metabolism and nutrition, but they also found a satisfying field of activity in numerous ailments, to recognise the earliest beginnings of which was the prerogative of medical science of to-day.

The business of the Congress was begun in general meeting, the subject for discussion being

The Therapy of the Troubles of Circulation.

Professor OTFRIED MULLER, of Tübingen, discussed the balneotherapy of these conditions. He said that a distinction must be made between the action of balneotherapy on the heart and on the vessels. The carbonic acid baths acted on both the heart and the vessels. Carbonic acid increased the number of the heart beats and the quantity of blood moved at each beat, and the vessels became either dilated or contracted according to the temperature of the water. Cool carbonic acid baths increased the quantity of blood but retarded the cardiac action; the heart worked more slowly, but more forcibly and more equably; the peripheral arteries became contracted, and those of the interior dilated; the blood pressure became higher and the respiration deeper, so that congestions were compensated. A carbonic acid bath was like a gymnastic lesson for the heart. In the hot bath the blood pressure decreased, the heart had less work, and thus was spared. Tepid baths produced a slight increase of the number of heart beats without a marked influence on the blood stream, and such baths should therefore be administered at the beginning of treatment.

Professor VAQUEZ, of Paris, spoke on the dietetics of circulatory troubles, and said that in arterio-sclerosis and increased blood pressure troubles of the circulation might be avoided by proper food. Patients suffering from arterio-sclerosis should eat rather little, avoiding as much as possible meat and salt. In severer cases vegetable food and milk were indicated; when troubles of circulation became obvious meat should be totally done away with. Patients with cardiac diseases should avoid salt, albuminous substances, and too large a quantity of fluid.

Dr. ZANDER, of Stockholm, spoke on the mechanotherapy of troubles of the circulation. He was of opinion that by gymnastic exercises the circulation in the lungs was rendered easier, so that more oxygen was absorbed by the muscles. The mechanotherapy thus acted less on the centre and more on the periphery of the circulation.

The Diet in Gout.

This was the subject of a paper read by Professor MINKOWSKI. He explained that the diet in gout must be free from purin substances, which produced an increase of uric acid. Purin was a production of the cell nucleus. The greater the quantity of cell nuclei the more uric acid was produced. Calf thymus contained ten times more purin substances than meat, milk only one-hundredth the quantity. Eggs, caviare, bread, potatoes, and rice were nearly free of purin; leguminous vegetables contained the same quantity of purin as meat; while a litre of beer contained as much purin as 100 grammes of meat.

Dr. A. E. GARROD said that he preferred a food with a small quantity of purin to a food without purin; a total withdrawal of these substances could not be borne for more than a short time without serious inconvenience and harm to the patient. He considered that the success of dietetic treatment was much exaggerated.

The Diet in Diabetes.

On this subject Professor VON NOORDEN, of Vienna, said that many patients could not bear the total withdrawal of carbohydrates and the reduction of albuminous substances in the food; sometimes this diet led to acidosis. In these cases oatmeal was indicated; other carbohydrates, such as lentils or wheat flour, were equally valuable, but he was of opinion that oatmeal had a specific action, the reason for which was as yet unknown. In severe cases of acidosis the administration of alkali was indicated. The value of mineral waters was much exaggerated.

Dr. LABBÉ, of Paris, recommended vegetable cures, alternating with days of fasting and days with albuminous diet, to avoid acidosis.

Dr. BLUM, of Strasburg, said that oatmeal was indicated in cases with imminent coma, in cases with troubles of digestion, and in cases where the sugar did not disappear on the withdrawal of carbohydrates.

The great number of papers and reports read before the Congress makes it impossible even to give the names of all the papers and speakers. It may be mentioned that in the Balneological Section Professor MACHE read a paper on the Absorption of Radium by Drinking and Inhalation Cures; Dr. MORTON, of London, spoke on the Use of Filters in Radio-therapy; and Mr. DEANE BUTCHER on the Rationale of Roentgen- and Radio-therapy. In the Section of Kinesitherapy Mr. R. C. ELMSLIE, of London, read a paper on the Physical Treatment of Tuberculosis of the Joints.

THE GERMAN CONGRESS ON ORTHOPÆDIC SURGERY.

(FROM OUR SPECIAL CORRESPONDENT.)

THE German Congress on Orthopædic Surgery was held in Berlin on March 24th and 25th, Professor SPITZY, of Graz, being in the chair. The principal subject of discussion was

Chronic Deforming Arthritis.

Professor KRAUS, of Berlin, gave a detailed description of the symptoms and the pathology of this disease. He distinguished an atrophic and a hypertrophic form according to the skiagram. Clinically, there are three different forms: infectious arthritis ensuing on tonsillitis or gonorrhœa, uric arthritis, and rheumatic gout. He concluded from his experiences that in the secondary symptoms radium preparations, including thorium X, have a curative action. Adrenalin is valuable in chronic infectious arthritis.

Dr. PONCET, of Lyons, said that some forms of chronic rheumatic arthritis were of tuberculous nature, as was proved by their association with tuberculosis in other organs and the reaction after tuberculin injection. Radium had no effect, but good results were obtained by heliotherapy.

Dr. IBRAHIM, of Munich, spoke on chronic arthritis in the juvenile age, and gave a description of this disease, of which the etiology is still rather obscure. He also believed that some cases were tuberculous.

Dr. PREISER, of Hamburg, spoke on the orthopædic treatment. He said that secondary alteration after progressive destruction must be treated by appliances after tenotomy. In angular ankylosis linear or cuneiform osteotomy was indicated. Plastic operation on the joints must be limited to gonorrhœic arthritis of the elbow or the knee. The rachitic pelvis produced in adolescence by over-exertion in standing, walking, and lifting heavy weights might lead to differences in the knee-joints and eventually to flat-foot. Contractions of the hip-joint must be treated by *brisement forcé*, and eventually by osteotomy.

Dr. PERTHES, of Leipsic, was of opinion that juvenile osteo-arthritis coxæ was caused by a focus of softening in the neck of the femur.

Dr. SCHAWN, of Werde, believed that arthritis deformans was a tuberculous process, which developed in advanced age and after abnormal exertion of the joint.

Dr. BADE, of Hanover, reported that he had seen in 71 of 131 cases of dislocation of the hip-joint after the setting a division of the epiphysis and anomalies of ossification on the head of the femur; these alterations were probably due to rachitis or osteomalacia, but not to arthritis.

Dr. AXHAUSEN, of Berlin, reported that he had produced by electrolysis on the cartilages of the joints the same alterations as those characteristic of deforming arthritis. He thus believed that necrosis of the cartilages was the cause of the disease.

The Non-operative Treatment of Pseudarthrosis of the Neck of the Femur.

Professor LORENZ, of Vienna, speaking on this subject, said that in patients until the age of 40, whose accident had occurred not longer than two months previously, the joint, after energetic mobilisation, was fixed by a plaster bandage in strong abduction and inward rotation. After three months the abduction became diminished and a Hessing splint was applied for one year. In patients whose accident had occurred three or four years previously the joint was mobilised and a raised sole applied. They might then walk a few days later. The results were very good.

The Treatment of Sciatica.

Dr. STOFFEL, of Mannheim, read a paper on the treatment of sciatica. He said that sciatica meant an affection of the sensory tracts of the nerve. After these tracts had been accurately made out they were exposed for a distance of 15 cm., and a resection was practised. The ascending degeneration which ensued on the operation led to good results.

Tendon-transplantation in Infantile Paralysis.

Dr. STOFFEL also spoke on transplantation of tendons in infantile paralysis. He said that the transplanted muscle must have the same anatomical structure as the paralysed muscle; tension or retraction must be avoided; the transplanted muscle cannot be used at the same time for a correction of the deformity.

Bone Implantation.

Dr. BRANDES, of Kiel, recommended the treatment of defects of the tibia by implanting the fibula at two operations into the remainder of the tibia, maintaining on each occasion a connexion with the proximal or distal end of the fibula.

Dr. PELTESOHN reported that he had bridged a defect of the ulna, with dislocation of the head of the radius, by implanting a piece of the fibula. The piece had completely grown together with the ulna. The function was good. The fibula had regenerated.

Other papers read before the Congress concerned the Treatment of Scoliosis, by Dr. E. G. ABBOTT, of Portland, Maine, U.S.A.; the Anatomy of Spina Bifida, by Dr. CRAMER, of Cologne; the Treatment of Hallux Varus, by Dr. LUDLOFF, of Breslau, and others.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Certification Scheme.

UP to the time of writing the Insurance Commissioners have not made known how they propose to deal with certification in those areas where medical men have refrained from putting their names on the certification panels—that is to say, in by far the greater part of the country. Threats have been thrown out of appointing salaried officers to carry out the work, but it would be difficult or impossible to establish an effective scheme on such lines. A circular letter was issued a week ago by the Commissioners to medical men who had put their names on the panels declaring that, as arrangements had taken longer than was expected, the panels could not yet be published. It was added that capitation fees would be paid to medical men on the panels in respect of each insured person to whom they would furnish certificates under the Act, as well as for those who might subsequently select them as their panel doctors. The Commissioners appear also to contemplate removing from some of the Insurance Committees the administration of the panel scheme. Last week a deputation of the Conjoint Committee discussed with the Commissioners the Regulations governing certification, apart from questions of finance, and the Commissioners agreed to make certain amendments to meet the views of the profession. The Commissioners have also in hand the preparation of a scheme for payment for certificates under the National Insurance Act required at hospitals, no provision having been made for this in the panel scheme.

Sudden Death of a Dublin Physician.

The death occurred suddenly on April 7th of Dr. W. R. Evans, a respected member of the medical profession in Dublin. He had just finished addressing a religious meeting when he was noticed to be ill, and death occurred in a few minutes. Some hours later his sister succumbed as a result of the shock of her brother's death. Dr. Evans had practised in Dublin for over 40 years, and for some time was physician to the Orthopædic Hospital.

Free Choice of Doctor in Belfast.

There seems to be a tendency on the part of some of the Approved Societies to limit the free choice of doctor. The matter came up at a meeting of the Belfast Local Medical Committee on April 10th, when a letter was brought before those present which had been sent out by the secretary of one of these societies stating that the society he represented was recommending the names of several doctors whose certificates in the past they have found they could rely upon, and in whom they have perfect confidence, as those from whom certificates would be received, and asking those to whom the letter was sent to join. A resolution was passed and has been sent to the public press protesting against such action on the part of Approved Societies, and pointing out to the insured that they had all the right of free choice of doctors on the panel. The secretary of the Local Medical Committee was instructed to send a note to the members of the profession in Belfast warning them to have nothing to do with such requests from any Approved Societies. He was also instructed to write to the Irish Insurance Commissioners and to the Belfast Insurance Committee drawing their attention to this attempt to make limited panels. It seems that in Belfast, as in other places, a difficulty is likely to arise in regard to those insured patients who have not chosen a doctor as to how they are to be allotted; the easiest way will be, as has been suggested, to divide them among the practitioners by a combined body consisting of representatives of the Insurance Committee and the Local Medical Committee.

Infectious Disease in Belfast.

Typhoid fever, which it was hoped had disappeared from Belfast where in former years it was endemic, has again become prevalent, as in January of 1913 there were 10 notifications, in February 16, and in March 13. Since October 600 cases of scarlet fever have been reported and more than 300 cases of diphtheria (154 were notified in March). In February and March 13 deaths occurred from scarlet fever, 2 from typhoid fever, 14 from diphtheria, 77 from measles, and 12 from whooping-cough. During the same period 148 deaths were due to pulmonary tuberculosis.

The late Dr. Cecil Edward Shaw.

It is with sincere regret that I announce the death, after a long illness, at his residence in Belfast on April 10th, from pernicious anæmia, of Dr. Cecil Shaw. Dr. Shaw, who was in his fiftieth year, was the youngest son of the Rev. George Shaw, a well-known Belfast clergyman. Educated at the Royal Academical Institution, Belfast, and at Queen's College, he graduated both in arts and in medicine (he obtained the M.D. in 1887) in the Queen's University of Ireland. Deciding afterwards to specialise in the departments of the eye, ear, and throat, Dr. Shaw studied in London, Marburg, Vienna, and Paris, and subsequently began practice in Belfast, where he was appointed ophthalmic surgeon to the Mater Infirmorum Hospital, and assistant surgeon to the Belfast Ophthalmic Hospital, and on the death of Dr. W. A. McKeown he was selected as lecturer in ophthalmology in Queen's College, now the Queen's University of Belfast. Dr. Shaw was a man of wide culture and one of the best amateur photographers in the north of Ireland. Thoroughly conversant with the literature and practice of his own specialty, he gave the greatest personal attention to his hospital and university work, while among his private patients he was most popular. Dr. Shaw was married, but had no family. Sincere sympathy is felt for his widow.

April 15th.

Obituary.

SIR HENRY ROSBOROUGH SWANZY, HON. M.D. DUB., HON. D.SC. SHEFFIELD, F.R.C.S. IREL.,

LATE PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND; SURGEON TO THE ROYAL VICTORIA EYE AND EAR HOSPITAL, DUBLIN.

SIR HENRY SWANZY, HON. M.D. DUB., HON. D.SC. SHEFFIELD, F.R.C.S. IREL.

(From a photograph by Messrs Elliott and Fry, Limited, London.)

Sir Henry Swanzy died at his residence, 23, Merrion-square, Dublin, last Saturday evening, after a few days' illness. He had been suffering for some days with influenza, when heart failure occurred. Few of his colleagues had heard of his illness, and the news of his death, appearing in Monday's papers, gave rise to surprise and sorrow.

Henry Swanzy was born in 1844, the son of a Freeman of the City of Dublin. He was educated in Trinity College, Dublin, where he graduated M.B. in 1865, becoming a Licentiate of the Royal College of Surgeons in the following year. After graduation he spent several years in study abroad, working chiefly at Berlin and Vienna. He was for some time assistant to von Graefe, and he served as surgeon in the Prussian army in the campaign of 1866. Returning to Dublin, he devoted himself to practice as oculist and aurist. He became a Fellow of the Royal College of Surgeons in 1873, and ever since was much interested in the affairs of that corporation. He joined the staff of the National Eye and Ear Infirmary, which some 16 or 17 years ago amalgamated with St. Mark's Ophthalmic Hospital to form the Royal Victoria Eye and Ear Hospital. The union was brought about to a great extent by Swanzy's influence, and he devoted himself heartily to the task of collecting funds for the fine building which now houses the institution. He was for many years ophthalmic surgeon to the Adelaide Hospital.

In later years honours came thick on Swanzy. His own University conferred on him the honorary degree of M.D., and the University of Sheffield that of D.Sc. He was Bowman Lecturer in 1888. His position was recognised by the medical profession in a marked manner, when in 1897 he was elected president of the Ophthalmological Society of the United Kingdom, a post which he held for two years. He was president of the Royal College of Surgeons in Ireland from 1906 to 1908, and was universally allowed to have discharged his office with efficiency and dignity. In January, 1907, he received the honour of knighthood. In 1911 he was selected as president of the Ophthalmological Section of the International Congress of Medicine which is to meet in London next August, and his loss from the deliberations of that gathering will be felt by many of the foreign representatives, as his work was well known and much appreciated on the continent.

To the literature of ophthalmology he contributed much, and the tenth edition of the well-known "Handbook of Diseases of the Eye and their Treatment," written conjointly with Dr. Louis Werner, was reviewed in our columns as recently as May of last year. The merits of this text-book were recognised on its first appearance and for a long time, despite the increase of ophthalmological knowledge and the consequent difficulty in keeping pace with it in any text-book, the author produced edition after edition unaided. Dr. Werner's name appears on the title page for the first time in 1907, when the book had reached its ninth edition. Hitherto it had been essentially a student's book, but much new matter was added to the ninth edition, and many rare conditions were treated with greater fulness. In many ways the tenth, and last, edition was again an improvement, and we may be permitted to hope that this will prove one of those manuals which long survive the man who originally planned them. Swanzy was also the author of the article on Eye Diseases and Eye Symptoms in their Relation to Organic Diseases of the Brain and Spinal Cord in the "System of Diseases of the Eye," by British and foreign authors, published in London and Philadelphia, and contributed many valuable papers to the Reports of the Ophthalmological Society.

Swanzy's personal character was as rare as his scientific attainments. Intelligence, quickness of perception, judgment, struck even the casual observer. But to those who knew him the prevailing characteristic was his single-mindedness. Whatever his object was—the treatment of a patient, the
success of hi
he was a Fel
anything to
stupidity, ar

and his tongue was sharp when roused. But he bore no rancour, and he was always ready with generous excuses for the failings of others. His keen humour brightened many a dull debate.

Swanzy had a deep love of science, of his profession, and in particular of the Dublin School of Medicine. He maintained a high scientific standard in his own work, and expected as much from others. In recent years he spent much time in the work of the Research Defence Society and was one of the honorary secretaries of the Dublin branch. He was one of the most industrious workers on the Council of the Royal College of Surgeons. Last year he devoted much time to the arrangements for the bicentenary festival of the Medical School of Trinity College, and he was one of the honorary treasurers of the fund which is being raised to perpetuate the memory of that occasion.

He married Mary Knox, the eldest daughter of Dr. John Denham, and granddaughter of the late Major F. A. S. Knox, R.A., by whom he had three daughters.

In the death of Sir Henry Swanzy we have lost one of whom the profession had reason to be proud, not only as a man of science and a surgeon, but still more as a man of high character and noble ideals, in whom there was nothing petty.

CHARLES TOZER SAVORY, M.D. ST. AND., M.R.C.S. ENG., L.S.A.

Dr. C. T. Savory, who died on March 27th, was born in 1829 in the City of London. He was educated at Ramsgate, and was originally intended for a commercial life. Thus he did not commence the study of medicine until his 30th year. He was probably largely influenced to this course by the brilliant example of his elder brother, the late Sir William Savory, who was thrice President of the Royal College of Surgeons of England. Charles Savory was a student at St. Bartholomew's Hospital, and in 1862 became a Member of the College of Surgeons and a Licentiate of the Society of Apothecaries. He afterwards graduated at the University of St. Andrews. He practised for 45 years in Stoke Newington and Canonbury in partnership with the late Mr. Edmund Pettifer, who had been a fellow student with him at St. Bartholomew's Hospital. He retired from practice about six or seven years ago, and the last years of his life were spent in retirement at his residence at Crouch End, where he died at the ripe age of 83, having outlived most of his contemporaries.

Dr. Savory was twice married and leaves a numerous family. He was a man of wide reading and culture, charitable and unostentatious; of handsome and dignified presence, he bore a close resemblance to his better-known brother. (FROM OUR OWN CORRESPONDENT.)

An Unsuspected Danger to School Children.

HYGIENISTS are directing their attention to a hitherto unsuspected source of danger to health. In the public schools it is customary to reward good work and good conduct with crosses or medals, which are worn by the boys—and especially girls—to whom they are awarded. Daily or weekly, according to the regulations of the particular school, these badges change hands on fresh award. As for the most part the children are not content merely to wear them, but contract the habit of sucking and biting them, they afford a sure and easy method for the transmission of infections.

Emetine in the Treatment of Amœbiasis.

At the Société Médicale des Hôpitaux on April 4th M. Dopter brought forward some new facts concerning the remarkable efficacy of emetine hydrochlorate in a case of hepatic abscess and of many sufferers from amœbic dysentery. A patient, invalided home from Indo-China, entered Val-de-Grâce for an abscess of the liver, the first symptoms of which made their appearance in October. On making an incision it was found that the abscess had burrowed into the subcutaneous cellular tissue, where it formed a button-shaped abscess. On opening the latter a large hepatic pouch was found, from which escaped about a litre of characteristic chocolate-like pus, which was found on microscopic examination to contain some amœbæ of dysentery. The examination of a fragment of the wall of this cyst revealed numerous similar parasites. That day and on the following days 0·04 gramme of emetine hydrochlorate was injected under the skin of the thigh. As a result of this treatment the discharge of pus quickly subsided, so that at the end of about a wee[illegible] no longer soiled. At the same time the [illegible] ondition, which had been very precarious, rapidly improved. M. Dopter related three other cases of amœbic dysentery of several months'—one of them, indeed, of two years'—duration, in which the use of emetine in like manner caused rapid disappearance of the colic, the tenesmus, and the muco-sanguineous stools, the stools rapidly recovering their normal character. A cure was effected in a few days. Emetine, said M. Dopter, deserves extensive employment in the colonies, especially where intestinal or hepatic amœbiasis carries off yearly a great number of victims.

Medical Study Travel.

The thirteenth Voyage d'Études Médicales to the mineral waters and climatic stations of France will take place from August 25th to Sept. 6th next, under the presidency of Professor Landouzy, doyen of the Faculty of Medicine. It will take in the stations of the South-West of France in the following order: Arcachon, Dax, Biarritz, Hendaye, Cambo, Salies de Béarn, Pau, Saint-Christau, Eaux-Bonnes, Eaux-Chaudes, Argelès, Barèges, Saint-Sauveur, Gavarnie, Cauterets, Bagnères de Bigorre, Capvern, Barbazan, Siradan, Bagnères de Luchon. Several bursaries have already been offered to the Voyage d'Études Médicales of 1913 by Professor Henrot, and the Sociétés des Eaux Minérales of Evian-Cachat, Pougues, Vichy, and Vittel-Grande Source. Further information can be obtained from Dr. Carron de la Carrière, Rue de Bagnolet 24, or from Dr. Jouaust, Rue Frédéric-Bastiat 4, Paris.

Sleeping Sickness.

An important meeting, which was attended by many eminent medical men, by delegates from the Ministries of the Colonies, and by high officials and agriculturists of Africa, took place recently at the Union Coloniale to discuss means for fighting against the sleeping sickness in Equatorial Africa. Dr. Aubert, director of the Institut Pasteur of Brazzaville, made some comparatively reassuring observations. For a considerable time the disease has ravaged Africa, destroying entire populations. But in the past four years we have ceased to be entirely defenceless against it. By injections of atoxyl it has been found possible to immunise patients for some months, so that for this period they cease to be sources of contagion. Moreover, two remedies, both derivatives of arsenic, which appear to produce a complete cure, hitherto unattainable, are being experimented with. Dr. Mouleyrat announced that he would place specimens of these products at the disposition of colonial medical officers who wished to make trial of them. Resolutions were passed at the meeting urging the necessity for increasing the number of medical men in Equatorial Africa, for even if the means exist for fighting this scourge the colony almost entirely lacks medical men to apply them. The stringent application of the regulations regarding sanitary passports was recommended, for the sufferer, if allowed to travel, spreads the disease. In the regions most affected delimitation of areas to be placed each under the supervision of a medical man is urged. This medical man should cause the entire administrative routine to be subordinated to the necessity for caring for these patients. Since the physiologically poor condition of the natives predisposes them to the disease, all measures fitted to improve their nourishment and general condition should be taken. In particular the meeting showed itself very favourably disposed towards the establishment of small land holdings among them.

Migraine of Ethmoidal Origin.

Before the Academy of Medicine, on April 8th, M. Guisez showed that in nearly 70 cases in which persons had suffered for many years from attacks of headache that resisted all medical treatment, regimen, and even nerve resection, he had found the cause of these migraines to be certain malformations sharply limited to the middle and upper part of the nose in the ethmoidal region. The attacks always began near the fronto-nasal region, around the root of the nose or immediately above the eyeballs, and the pain was always more marked on one side than the other. The pain subsequently became generalised all over the head, being most marked, however, in the frontal region. The attacks often lasted 24 hours, sometimes with nausea and vomiting, and might lead to a condition of profound organic degeneration. Examination of the nose showed hypertrophy of the middle turbinated or of the bulla of the ethmoid. The nasal bone might be pushed outwards. The mucosa was sometimes in a state of myxomatous degeneration, and polypi filled the middle meatus. A cure was obtained by simple local treatment—resection under local anæsthesia of the head of the middle turbinated bone, of the ethmoidal bulla, and removal of polypi—that is, of everything tending to enlarge the region of the upper and middle meatus.

April 15th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Number and Distribution of Medical Students in Austria.

THE total number of medical students in the Austrian universities was 6439 in the last winter half-year, or about 24 per cent. of the total number of university students in this country. The distribution of these medical students among the several universities was as follows: in Vienna, 2824, with 160 females; in Graz, 572, with 12 females; in Innsbruck, 350, with 3 females; in Prague, 572 German and 932 Bohemian students, with 71 females; in the Polish University of Lemberg, 523 males and 106 females; and in the Polish University of Cracow, 529 males and 62 females. In Czernowitz there were no medical students. It is interesting to note that the number of medical students, and especially of female medical students, has been constantly increasing for more than ten years. Whilst the general population has been increasing about 2 per cent. per annum, or 20 per cent. within the last decade, the total number of medical students has gone up by 150 per cent in the same time, and the female medical students have increased by over 400 per cent. On the other hand, the number of foreign students is going down constantly, mostly for political reasons, because Russian and Balkan students formerly flocked to Vienna, but holders of American and English diplomas come here in increasing num[illegible]. The figures mentioned above [illegible] n interesting step by the med[illegible] of Medical Councils have given public notice that the medical profession will soon be more than overcrowded, and have asked all the authorities concerned in the management of schools, as well as other public corporations, to warn pupils from taking up this line of study if they intend to follow medical practice as a means of livelihood. They have also explained that at present it takes at least five years to obtain permission to pass the final examinations, which themselves occupy half a year, and a student must afterwards spend at least another two years in hospital study, making 28 years the minimum age at which a practitioner can commence to earn his living. It is accordingly pointed out that the financial prospects for the medical profession will be less than moderate during the next 10 or 15 years, so that unless intending medical students have at least the expectation of an independent income they would do well to take up some other occupation.

Compulsory Vaccination in the New Austrian Provinces.

The administrative authorities of Bosnia and Herzegovina, the Balkan provinces acquired by Austria a few years ago, have passed a law making vaccination compulsory. Every child living in these two provinces, the population of which is nearly 2,000,000, must be vaccinated before it is 2 years old, only such children being exempted as have either had small-pox or are too ill to have the operation performed. Every child must be revaccinated in the eighth year of its age. If the operation is unsuccessful it must be repeated in the following year, and if again unsuccessful it must be repeated two years later. Every case of vaccination must be notified to the Board of Health and the officers of public health. This law has been passed because a large number of immigrants from the area affected by the Balkan war have come into Austria and have frequently been the means of introducing small-pox.

Professor Kraus.

The well-known bacteriologist, Professor Rudolf Kraus, head of the Serotherapeutic Institute in Vienna, has accepted an invitation to become director of the Institute for Infectious Diseases in Buenos Aires. His duties will be similar to those he has performed in Vienna, for the institute will prepare protective and prophylactic substances for use in connexion with infectious diseases affecting both man and the lower animals. He will also have to organise general measures for the prevention of these diseases. His departure will be a serious loss for our university. He is an eminent authority on the problems of immunity, and not long ago, on the invitation of the King of Bulgaria, he visited the seat of war in the Balkan area for the purpose of advising the military authorities with regard to the prevention of cholera. Professor Kraus will start for his new sphere of work in the month of June or July.

A Peculiar Case of Cerebral Disease.

At a recent meeting of the Vienna Gesellschaft der Aerzte Professor Benedikt showed a female patient, 48 years old, who had been brought to him with symptoms of deafness and paresis of the extremities on the left side. She was mentally unstable; her right ear completely deaf, and her left ear partly so. Sensation of temperature was diminished; the glands behind the sternomastoid muscle were enlarged on both sides, and glands elsewhere could be palpated. Professor Benedikt said that the chief interest of the case was in the contralateral coexistence of deafness and paresis of the limbs, and in the fact that the gait, the position of the fingers and of the whole body, as well as a tendency to propulsion, were very similar to the syndrome found in paralysis agitans. He considered that the combination of symptoms existing in this patient was not necessarily of syphilitic origin, although she had had several miscarriages and a positive Wassermann reaction had been obtained from her. In his opinion too much importance was attached to this serum reaction in cases of tabes and general paralysis of the insane, much to the detriment of the patient. In the patient whom he was showing he suspected cancer in the brain, since a tuberculous nodule could be excluded, and he ordered the administration of ortho-silicate, which has lately been so much advocated in the treatment of cancer. The result was most favourable, for within three months the patient was much improved in every respect, and even her mental activity has been restored. He also reported some experiments with the same treatment in cases of long-standing syphilis in which the central nervous system was attacked (syphilitic hemiplegia), the results being also excellent, and he emphasised the necessity of treating patients *operated* on [illegible]. The same substance in order to prevent recurrence. He gave doses up to 2 centigrammes (one-third of a grain) dissolved in 1 gramme of distilled water per day.

April 12th.

UNITED STATES OF AMERICA.

(FROM OUR OWN CORRESPONDENTS.)

The late Dr. Prince Albert Morrow, of New York.

Dr. Prince Albert Morrow, the dermatologist and syphilologist, but perhaps even more widely known for his studies in sex hygiene and as a founder of the American Society of Sanitary and Moral Prophylaxis, died suddenly at his home in New York on March 17th, at the age of 66. He was a native of Kentucky, and was educated at Princeton College and at the New York University. He took his A.B. at the former College in 1865 and his M.D. at the latter University in 1874. From 1884–1904 he was attending surgeon at the City Hospital, New York. He was appointed lecturer on dermatology in 1882–3, clinical professor of venereal diseases in 1884, and of genito-urinary diseases in 1886. In 1890 he became emeritus professor of the University and Bellevue Hospital Medical College. For 14 years he was attending physician in the skin and venereal diseases department of the New York Hospital. He was also consulting dermatologist to the St. Vincent's and the City Hospitals. In 1907 he was chairman of the section on hygiene and sanitary science of the American Medical Association, having previously (1890–91) been president of the American Dermatological Association. He had been also president of the American Society of Sanitary and Moral Prophylaxis since its foundation in 1905. Dr. Morrow's literary work includes the editorship of the *Journal of Cutaneous and Venereal Diseases*, of which he was one of the founders, from 1882 to 1892. In 1888 he published an "Atlas of Skin and Venereal Diseases," and in 1892 "A System of Genito-urinary Diseases, Syphilology, and Dermatology," in three volumes. To these must be added a monograph on Leprosy (1899), and particularly his work on "Social Diseases and Marriage," which appeared in 1904.

Woody Phlegmon.

In a paper read before the Chicago Medical Society on Feb. 19th last, and reported in the *Journal of the American Medical Association* of April 5th, Dr. W. W. Grant, of Denver, says that it is probable that this disease occurs under some name or form more frequently than has been reported. Its literature is mostly recent, and is reviewed by Grant, who reports two cases in which the phlegmon occurred on the abdominal wall. In both cases bacteriologic examinations were made and staphylococcic infection determined. The cancerous theory will probably soon be abandoned, and, he says, with our existing knowledge, we are justified in concluding that the disease generally occurs after middle life in persons whose resistance has been impaired by previous ill health. The immediate cause is a slow infective process with or without trauma. The dictum of Reclus that it is not due to specific bacteria, but to a variety of germs of mild virulence, seems confirmed. The staphylococci seem to be the chief offenders. The usually slow and protracted course and final resolution are characteristic. Hyperleukocytosis always exists. Grant concludes that the disease will be cured more quickly and completely by free incision (not excision) and serum treatment than by any or all other means known at the present time, and early diagnosis will make the cures more frequent and rapid.

The Eugenics Record Office.

This office was established at Cold Spring Harbour, Long Island, in October, 1910, by Mrs. E. H. Harriman, with the assistance of Mr. John D. Rockefeller, and has recently entered upon a new stage of its development. A board of scientific directors has been organised, comprising Dr. Alexander Graham Bell, chairman; Dr. William H. Welch, professor of pathology, Johns Hopkins Hospital, vice-chairman; Professor Irving Fisher, Yale University; Professor Lewellys Barker, of Johns Hopkins Hospital; Professor E. E. Southard, of Harvard University, and director of the Psychopathic Hospital, Boston; and Dr. C. B. Davenport, secretary of the board and resident director. The board met at Cold Spring Harbour on March 21st and organised its work. The aim of the Eugenics Record Office was defined to be as follows. First, to promote researches in eugenics that shall be of utility to the human race. This part of the programme includes: the study of America's most effective blood lines, and the methods of securing the preponderance and relative increase of the best strains; the study of the origin of, and the best methods of restricting, the strains that produce the defective and delinquent classes of the community; the study of the method of inheritance of particular traits; the study of the consequences of the marriages of close kin; the study of miscegenation in the United States; the study both in this country and abroad of the family histories of permanent immigrants. Second, to publish the results of these researches. Third, to provide a fireproof building for the preservation of eugenical records, including genealogical works and town histories. Fourth, to provide an administrative office and staff to carry out the work. The fireproof building provided by Mrs. Harriman which is to form the new home of the office is being rapidly completed. The board of scientific directors will meet each spring at Cold Spring Harbour to consider the projects most worthy of support during the ensuing year, which begins October 1st, and it will meet again in November to receive a report of the work of the office in the preceding fiscal year. The resident director has general charge of the plant and its operations, and is authorised to ask for and receive, in the name of the board, funds to carry on the work of the office. The board voted in favour of the organisation of a eugenics research association, of which a meeting will be called early in June.

Dr. Friedmann's "Cure" for Tuberculosis.

A statement has been published by the United States Public Health Service[1] with reference to the appointing of a board of medical officers to make a thorough investigation of Dr. Friedmann's alleged cure for tuberculosis. The board has arranged for a series of demonstrations of his remedy by Dr. Friedmann in certain New York hospitals, and they are to be continued until sufficient information has been obtained for forming an opinion as to the merits of the treatment, which will require considerable time. The board has received a culture from Dr. Friedmann and will experiment with it in regard to Dr. Friedmann's claims as to its harmlessness in warm-blooded animals. The subjects for experiments are selected by the hospital authorities with their own consent from among their own patients, and only a small proportion of the available volunteers can be used. The board particularly cautions against placing any credence in statements in the press ascribed to any of its members, as no opinion has been, or will be, expressed until the work is sufficiently advanced to warrant some conclusion in the matter. The caution thus exhibited is eminently commendable, for there can be no doubt that incalculable injury is done, not only to individual patients, but to the progress of medical science, to individual remedies and methods under investigation, and to old and tried methods of undoubted service so far as they go by the optimistic enthusiasm of some press correspondents on this side.

April 8th.

---

[1] Bulletin of the United States Public Health Service, March 21st, 1913.

SWANSEA MEDICAL MEN AND CONTRACT PRACTICE.—The honorary medical staff of the Swansea General and Eye Hospital have issued a communication expressing their sympathy with the medical men of Swansea and district in their endeavour to secure more adequate remuneration for contract practice than has hitherto obtained, and their surprise and indignation at learning that the just and moderate demands of their colleagues have been met with an attempt to establish in the town a medical aid association. Recognising that underpaid medical work is equally as bad for the patient as for the doctor, the staff have decided that in the event of the establishment of any society or association, having for its object the employment of medical men under conditions not approved of by the medical profession, they will under no circumstances meet in consultation or have any professional dealings with any medical man holding office under the same, whether in connexion with a patient at his own home or at the hospital. Moreover, they will decline, except in cases of the gravest emergency, to treat in hospital any member of such society. Further, the staff will adopt the same attitude towards medical men undertaking contract work on terms below those decided upon by the medical profession of any district.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At the examination in sanitary science held recently the following candidates were successful in both parts of the examination:—

Wallace Wright Adamson, Alexander Brownlee, *George Robert

John Davidson Smith, *William Templeton, Frederick Edward Apthorpe Webb, Arthur Robartes Wellington, and Leonard Stephen Willox.

* With distinction.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At the quarterly examination in Practical Pharmacy held on April 10th the following candidates were approved:—

UNIVERSITY OF LIVERPOOL.—At the examination for the Diploma in Tropical Medicine held recently the following candidates were successful :—

J. G. Becker, C. Forsyth, M. C. R. Grahame, K. K. Grieve, A. R. Hargreaves, P. Hiranand, O. E. Jackson, M. MacKelvie, J. McP. MacKinnon, R. J. A. Macmillan, C. E. P. Mouat-Biggs, E. Olubomi-Beckley, D. S. Puttanna, J. H. Reford, F. D. Walker, U. B. Yin, and W. A. Young.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Edmund Forster, *privat-docent* of Neurology, Dr. O. Vogt, Principal of the University Neuro-biological Institute, and Dr. Max Bielschowsky, assistant in the same institute, have been granted the title of Professor.—*Budapest:* Dr. Geza Krepuska, *privat-docent* of otology, has been promoted to Extraordinary Professor.—*Clausenburg (Kolozsvar):* Dr. Elemer Veress, extraordinary professor of biology, has been promoted to Ordinary Professor.—*Gratz:* Dr. Hermann Pfeiffer, extraordinary professor of forensic medicine, has been appointed Extraordinary Professor of General and Experimental Pathology. Dr. Johann Habermann, extraordinary professor of otology, has been promoted to Ordinary Professor.—*Heidelberg:* Dr. P. Lenard, professor of physics, will commence work as Principal of the New University Institute for Radium Research on May 1st.—*Kiel:* Dr. O. Lubarsch, professor in the Düsseldorf Academy of Practical Medicine, has been appointed to the chair of General Pathology and Pathological Anatomy, in succession to the late Dr. Heller.—*Königsberg:* Dr. Ernst Hedinger, professor in Basle, has been offered the chair of Pathological Anatomy, in succession to Dr. Henke, who goes to Breslau. Dr. Paul Bartels, *privat-docent* of anatomy, has been granted the title of Professor. Dr. Henke has been recognised as *privat-docent* of Otology, Laryngology, and Rhinology.—*Leipsic:* Dr. Tillmans, extraordinary professor of surgery, has been promoted to Ordinary Professor. Dr. Ebstein has been appointed Senior Physician of the University Medical Clinic.—*Lemberg:* Dr. Anton Jurasz, extraordinary professor of laryngology and otology, has been promoted to Ordinary Professor.—*Marburg:* Dr. F. Kirstein has been recognised as *privat-docent* of Midwifery and Gynæcology, and Dr. H. Kleinschmidt as *privat-docent* of Pædiatry.—*Padua:* Dr. U. Baratozzi and Dr. A. Farini have been recognised as *privat-docenten* of Medical Pathology, Dr. R. Cecca and Dr. G. Marchetti as *privat-docenten* of External Pathology, Dr. Megardi as *privat-docent* of Ophthalmology, and Dr. F. Silvestri as *privat-docent* of Pædiatry.—*Parma:* Dr. B. Bacchi has been recognised as *privat-docent* of Forensic Medicine.—*Pisa:* Dr. G. Bernardi has been recognised as *privat-docent* of External Pathology.—*Prague (Bohemian University):* Dr. V. Guttmann has been recognised as *privat-docent* of Otology, Laryngology, and Rhinology.—*Strasburg:* Dr. Karl Spiro, *privat-docent* of physiological chemistry, has been promoted to Honorary Professor.—*Tours:* M. Villedieu, first-class pharmacist, has been appointed Professor of Chemistry and Toxicology.—*Turin:* Dr. C. Provera has been recognised as *privat-docent* of Surgery and Operative Medicine.—*Vienna:* Dr. Ottokar Chiari, extraordinary professor of laryngology and rhinology, has been promoted to Ordinary Professor.—*Würzburg:* Dr. Köllner, assistant in the Berlin Ophthalmic Clinic, has been appointed Oberarzt of the University Ophthalmic Clinic.

DEATH FROM ANTHRAX AT WARRINGTON.—An inquest was held at Warrington on April 9th on the remains of a labourer, aged 49 years, who died from anthrax. The deceased had been employed at a tannery in Warrington, and complained that one of his eyes was feeling very sore. Two days later he was admitted to the infirmary, where it was found he was suffering from anthrax. The manager of the tannery said the deceased had been working amongst some salted African hides, in which there was no disease. It was generally the China hides which were affected. Formerly they had used hides from China. At that time the firm came under the Home Office regulations with regard to the provision of washing materials for the men. At the present time they were only treating English, African, and Madagascar hides, and they found that that class of hide did not come into contact with the disease. Mr. W. H. Seal, H.M. Inspector of Factories, said, so far as the Home Office knew, it was not anticipated that there was any danger from imported hides from Madagascar. Careful inquiries would be made, and if it were found that this class of hide was also [illegible] would be made to the Home Office i[illegible] scheduled under the special conditions which covered the importation of China hides. A verdict of "Death from anthrax" was returned.

BRUSSELS MEDICAL GRADUATES' ASSOCIATION.—A dinner of this association, in connexion with the forthcoming Congress in Paris of the Royal Institute of Public Health, will be held under the presidency of Dr. Harold S. Sington at the Trocadero on Tuesday next, April 22nd, at 7 for 7.30. All graduates of the University of Brussels are welcome. Tickets (5*s.*, not including wine) may be obtained from the honorary secretary, Dr. Arthur Haydon, 23, Henrietta-street, Cavendish-square, W.

CHILDREN'S COUNTRY HOSPITAL AT HESWALL.—The annual meeting of the supporters of this hospital took place on April 10th. In the unavoidable absence of the Lord Mayor of Liverpool the chair was occupied by Alderman Leslie as deputy Lord Mayor. The committee in its annual report made a strong appeal for increased subscriptions. The institution, having for its object the treatment of children for such periods as would insure their restoration to health with the minimum amount of crippling of limbs or other organs, deserves every support, as these children, if not looked after in their young days, would later tend to become helpless drags on the community at large. Two new wards were opened by the Countess of Sefton. The extension increases the available beds to about 150, and it is intended to utilise the new wards, in part, for non-pulmonary cases of tuberculosis from Liverpool under the National Insurance Act. This latest addition to the building has cost about £7500. The ward on the upper floor, which has been named the Agnes Hunt Ward in honour of the noble work amongst sickly children performed by the lady of that name at Baschurch, is already in use, but that on the ground floor—the Holbrook Gaskell Ward—will not be ready for occupation for a few weeks. The former ward is on the open-air principle, but that on the ground floor will be reserved for children whose cases require more sheltered treatment. During the 14 years of Colonel Montgomery's energetic chairmanship £84,000 have been collected for building and for maintenance purposes, about £56,000 have been spent on buildings, and in invested funds there are about £27,000. From all sources over £14,000 were collected last year. The Countess of Sefton paid an eloquent tribute to the valuable services of Mr. Robert Jones, the honorary surgeon to the institution.

UNIVERSITY OF LONDON.—Sir William Collins and Dr. E. L. Gowlland have been appointed representatives of the University upon the governing boards of Christ's Hospital, Horsham, and the Wreight and Gibbs School, Faversham, respectively.—Dr. Arthur Robinson has been appointed Fellow of King's College.—Miss Maud Frances Forrester-Brown M.B., B.S., has been appointed to the Gilchrist Scholarship for Women.—Lectures in advanced medical subjects are to be delivered as follows: May 1st (5 P.M.), at St. Bartholomew's Hospital Medical School, Dr. M. H. Gordon, on Sensitised Vaccines; 5th (5 P.M.), at University College Hospital Medical School, Dr. T. R. Elliott, on Disease and the Suprarenal Glands; 8th (5 P.M.), at St. Bartholomew's Hospital Medical School, Dr. H. Williamson, on Some Factors of Importance in Determining the Significance of Albuminuria in Pregnancy; 19th, 21st, and 23rd (4.30 P.M.), at the London Hospital Medical College, Dr. H. M. Turnbull, on (1) Physiological and Pathological Changes in the Structure of Arteries, (2) Arterio-sclerosis; and 28th (4.30 P.M.), at the Brompton Hospital, Dr. C. H. Miller, on the Site of Tuberculous Lesions at Different Ages.—The following advanced lectures in physiology are announced to be given: A course of eight lectures on Surface Tension and Physiological Processes, by Professor A. B. Macallum, at the University, on Tuesdays, at 5 P.M., beginning on May 13th; three lectures on the Anatomy, Physiology, and Pathology of the Corpus Striatum, by Dr. S. A. Kinnier Wilson, at the University; eight lectures on the Physiology of Photosynthesis and Respiration in Plants, by Mr. E. F. Blackman, at University College, on Wednesdays, at 5 P.M., beginning on April 23rd; four lectures on the Physiology of Absorption, by Professor

T. G. Brodie, at King's College, on Wednesdays, at 4.30 P.M., beginning on May 21st; four lectures on the *Supposed Physical Basis of Life and Mind*, by Mr. J. S. Haldane, at Guy's Hospital, on Thursdays, at 4 P.M., beginning on May 8th; and eight lectures on the Factors concerned in the Volume and Form Changes of Cells (Growth and Movement), by Dr. H. E Roaf, at St Mary's Hospital Medical School, on Mondays, at 4 P.M., beginning on May 5th.

DONATIONS AND BEQUESTS.—By the will of the late Rev. C Bromley, of Maulden, Bedfordshire, the testator bequeathed £500 each to the Bedford County Hospital and the Yorkshire Home for Chronic and Incurable Diseases — Mr. John Jones, of Wrexham, has by will left £50,000 to the Wrexham Infirmary and has given for the use of the infirmary Roseneath House and grounds, Wrexham, and the Claremont Hydro, Rhyl.

HUNTERIAN SOCIETY.—The last meeting of the session will be held on Wednesday, April 23rd, at St Bartholomew's Hospital (Library), at 8.30 P.M. This will be the annual general meeting, and the election of officers for next session will be made At 9 P M the winner of the society's annual medal, Dr. A. Graham-Stewart, will read a paper, founded on his prize essay, and entitled "Raised Arterial Pressure and Arterio-Sclerosis," and the medal and certificate will be presented to him by the President

LITERARY INTELLIGENCE.—Henry Kimpton's Catalogue of Medical and Surgical Works, No. 129, for 1913, includes a number of atlases and illustrated works at reduced prices, among them the first series of the Index Catalogue of the Library of the Surgeon-General's Office, U S A. Also several medical curiosa and portraits of eminent medical men. The total number listed is 94.—Among the publications of Messrs Constable and Company, Limited, is a treatise by Mr. Walter Heape, F R S., on "Sex Antagonism," which deals among other matters with Totemism and Exogamy (including a study of Dr. Frazer's theories), Birthmarks, and Fundamental Sex Relationship.

SWISS VITAL STATISTICS FOR 1910.—In 1910 there were 96,669 births registered, a smaller number than in previous years. There were 97,296 in 1909, and 99,468 in 1908. The deaths for 1910 numbered 56,498, a percentage of 1·51 out of a total population of 3,735,049 This also constitutes a decrease in comparison with previous years—59,416 in 1909, 57,697 in 1908, and 59,252 in 1907 Tuberculosis, with 8449 deaths, heads the list with a percentage of 15: 6011 phthisis cases and 2438 of other tuberculous affections There has been no great reduction of deaths from phthisis during the last five years, the figures being 6008 (1909), 6150 (1908), 6063 (1907), and 6407 (1906) Pneumonia shows 4784 cases (8·5 per cent.), and cancer 4349 cases (7·7 per cent) The mortality from cancer during the last five years has not varied much, the figures being as follows: 4443 (1909), 4387 (1908), 4175 (1907), and 4342 (1906) Asthenia is responsible for 3599 deaths (6 4 per cent), and infantile gastro-enteritis for 2385 (4·2 per cent.) 2077 persons died in consequence of accidents (3·7 per cent), and there were 847 cases (1·5 per cent) of suicide Old age is notified in 2058 cases (3 5 per cent.) Only 150 deaths from typhoid fever were reported, and 2 fatal cases of small-pox Whooping-cough caused 741 deaths (1·3 per cent); diphtheria, 455 (0 8); measles, 352 (0 6); and scarlet fever, 100 (0 2)—the infectious diseases of childhood making together a percentage of 3.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Asylums Officers (Employment, Pensions, and Superannuation) Bill

Viscount WOLMER has reintroduced in the House of Commons his Bill "to limit the hours of employment of officers and servants in asylums and to amend the Asylum Officers Superannuation Act." It was read a first time and it has the support of Mr. CHARLES ROBERTS, Mr. STANIER, Mr WATSON RUTHERFORD, Mr. HIGHAM, Sir JOHN McCALLUM, Mr COTTON, Mr WARDLE, Mr. CHARLES CRAIG, Mr W. REDMOND, Sir DAVID BRYNMOR JONES, and Sir REGINALD POLE CAREW,

University Education in London.

The final report of the Royal Commission on University Education in London is published as a Parliamentary Blue book. A large section of it deals with the Faculty of Medicine, and most important recommendations are made in regard to it

Select Committee on Patent Medicines

Further evidence on behalf of the proprietary medicines section of the London Chamber of Commerce was submitted to the Select Committee of the House of Commons on Patent Medicines on Thursday, April 10th. Mr. E J PERRY, a consulting and analytical chemist, expressed the view that the publication of the formulæ of proprietary articles would not diminish their total sale, but would merely divert the trade from the hands of the original owners into those of imitators.

HOUSE OF COMMONS.

WEDNESDAY, APRIL 9TH.

Medical Certificates for Sickness Benefit.

[illegible]

Malingering under the Insurance Act

Mr C BATHURST asked the Secretary to the Treasury whether he was aware that owing to the delicacy of the panel doctors position in relation to persons insured under the National Insurance Act, it was being found increasingly difficult [illegible] check malingering, and that in [illegible] appointed with this object by t[illegible] approval of the Approved Societ[illegible] Insurance Commissioners favoured the same course being adopted in other administrative areas —Mr. ROBERTSON (on behalf of Mr. MASTERMAN) answered The matters referred to in the honourable Member's question are receiving the careful attention of the Commissioners.

Sanatorium Benefit in Ireland.

Mr T M. HEALY asked the Chief Secretary to the Lord Lieutenant of Ireland whether the county and city of Cork could now reckon on receiving their share from the sanatorium grant on the basis of [illegible] support for schemes by which beds were to be taken in their sana- [illegible] plating building sanatoriums for themselves, and in respect of accommodation, whether for adults or for children, which will be available in the future for any county Insurance Committee which may apply for it, will be a final charge against the £145,000 grant as a whole The share of Cork county and city in the grant [illegible] for it and I hope it will be come to very soon

Industrial Poisoning

Mr. SNOWDEN asked the Secretary of State for the Home Department [illegible] whether and [illegible] what [illegible] advice without appeal in any case to Parliament.—Mr. McKENNA answered: The records of poisoning in different industries and (where regulations have been made) the working of the regulations are closely watched by the Department. New codes and amendments of existing codes are prepared from time to time, as experience shows the need for further precautions. For instance, recently the rules for the manufacture of pottery have been completely recast. A code for lead smelting has been made, and a Departmental Committee is now engaged i [illegible] ch-building trade. As regards the last part [illegible] ust point out that when objections are taken, [illegible] or workmen, to regulations proposed by the Home Office and in pursuance of the Factory Act, a competent person is appointed to inquire into and report upon the objections. A thorough inquiry is made, the evidence of the representatives of the department and of all parties interested who desire to be heard is taken, and the commissioner reports the conclusions at which he arrives on a consideration of the evidence. No express obligation is placed by the Act upon the department to accept the conclusions of the commissioner, but it is obvious that conclusions arrived at by an independent commissioner after an exhaustive inquiry of this kind are bound to carry, and I think were intended by Parliament to carry, very great weight.

Milk Prosecutions.

Mr. C. BATHURST asked the President of the Local Government Board whether he was aware that in the boroug [illegible] elsewhere dairymen were being prosecuted und [illegible] Acts for using derivatives of boron for the [illegible] although in strict compliance with the milk and cream regulations recently issued by the Board; and whether, if these regulations were deemed to be contrary to the provisions of an Act of Parliament, he would, in fairness to the dairymen, bring in an amending Bill to legalise such regulations.—Mr. BURNS said in reply: I am not aware of any such prosecutions, but I may point out that the regulations prohibit the use of any preservatives in milk.

Tuberculous School Children.

Mr. HOARE asked the President of the Board of Education how many schools, residential and [illegible] how many received gra [illegible] tion authorities.—Mr. J [illegible] hospitals or sanatoria pr [illegible] are certified by the Board of Education and receive grants under the Education (Defective and Epileptic Children) Act, 1899. These hospita [illegible] r the treatment of children suffering fror [illegible] are nine non-residential open-air schc [illegible] its under the Act referred to which mak [illegible] whom the majority are tuberculous. All [illegible] t of the seven hospitals or sanatoria are [illegible] authorities.

THURSDAY, APRIL 10TH.

Aged Insured Persons and Medical Benefit.

Mr. ALDEN asked the Secretary to the Treasury whether the case of the insured person over 65 years of age in respect of medical benefit would be dealt with in any Bill amending the National Insurance Act.—Mr. ROBERTSON (on behalf of Mr. MASTERMAN) replied: I do not quite understand what amendment my honourable friend proposes should be inserted in the Bill. It is competent under Section 49 of the existing Act for societies and Insurance Committees to provide medical attendance as one of the benefits for persons becoming employed contributors over the age of 65. Money was voted in the recent supplementary estimates to help societies and committees desiring to provide medical attendance for such persons by a grant of 2*s.* 6*d.* per head, and the Commissioners at the same time issued a circular stating that this grant was available, and also containing information as to the rates of sickness benefit that could be provided in addition.

Medical Benefit in London.

Mr. TOUCHE [illegible] e Treasury when it was proposed to take [illegible] equacy of medical benefit in London.—Mr. [illegible] Mr. MASTERMAN) said: I am not prepared t [illegible] underlying the honourable Member's question. I may say, however, that the London Insurance Committee have instructed their medical benefit subcommittee to report as to whether the present system of medical benefit in London could be improved and to [illegible]

Mr. TOUCHE: *Is it not* [illegible] enefit in London is hopelessly inadequate?— [illegible] cannot admit the inadequacy.

Mr. TOUCHE asked the honourable gentleman whether every person who had made application for permission to contract out under the National Insurance Act had received Form 43/IC, and whether many of these forms had been returned to the Insurance Committee for the county of London, or whether he had information that doctors were refusing to sign the undertaking in Part II. on the ground that its provisions were objectionable; and would a more acceptable form be substituted.—Mr. ROBERTSON answered: I am informed by the London Insurance Committee that the answer to the first part of the question is in the affirmative, and with regard to the second part of the question that 2000 or 3000 forms had been returned to the Committee. In some cases the doctors had refused to sign the undertaking referred to. The sums available for the medical attendance of persons making their own arrangements are the same as those of persons receiving attendance under the panel system, and the effect of the undertaking referred to is to secure that doctors treating them should render the same necessary services as doctors on the panel are required to render under the conditions attached to the payment of the Parliamentary grant. I see no reason why any modification of its terms is required.

Mr. TOUCHE: Is there any ground for the impression that the terms of that undertaking have been so drawn as to discourage contracting out?—Mr. ROBERTSON: They may have to some extent, as the conditions are the same.

Mr. TOUCHE asked whether a Local Medical Committee for the county of London had been formed and recognised in accordance with the Act; and, if so, how many doctors took part in the selection of the committee.—Mr. ROBERSON answered: No Local Medical Committee for the county of London has been recognised by the Insurance Commissioners.

Mr. TOUCHE: Does it not arise that no committee is entitled to style itself the Local Medical Committee for the county of London?—Mr. ROBERTSON: I should think so, but I am not sure.

Insured Persons at Surgeries.

Mr. TOUCHE asked the Secretary to the Treasury whether, in connexion with the administration of the National Insurance Act, due consideration had been given to the fact that it was not of advantage, either to the public health or to that of an insured patient, that he should be forced to wait, often for hours, in a grossly overcrowded room with other patients on each visit to the doctor; and if any effective measures were in contemplation to remedy this drawback.—Mr. ROBERTSON (on behalf of Mr. MASTERMAN) answered: I do not think that there is any ground for supposing that the conditions suggested in the honourable Member's question are likely to occur except in rare intervals, but if any complaints are made of this nature to an Insurance Committee it would be the duty of the Committee to take steps to remedy them.

Scottish Clerks Association and Medical Benefit.

Answering Mr. C. PRICE, Mr. ROBERTSON said: The Scottish Insurance Commissioners have had a conference with the representatives of the Scottish Clerks' Association and arranged with them that the Association should issue medical tickets to its members. At the same time the Commissioners agreed to suggest to Insurance Committees that members of the Association might, if practicable, be allowed an extension of time for the choice of a doctor, and so far as they are aware, the members are not experiencing difficulty in obtaining medical benefit. The Commissioners are, however, arranging a further conference with the Association within a few days.

South Shields Insurance Committee.

Mr. ROBERTSON, replying to Mr. HUDSON, said that he was informed by the South Shields Insurance Committee that they had not arrived at any such decision as to limit the choice of doctors to insured persons in their area to such doctors on the panel who at present had less than 800 insured persons on their lists.

Elementary Schools in Scotland.

Mr. LEICESTER HARMSWORTH asked the Secretary for Scotland what steps, if any, he proposed to take to carry out the recommendations contained in the report on the medical inspection of school children in Scotland by Dr. Leslie Mackenzie, particularly as to the increase of cloakroom accommodation, methods of cleaning, and sanitary accommodation, the present conditions of which were described therein as being responsible for disease and infection.—Mr. McKINNON WOOD wrote in reply: As regards cloakroom and sanitary accommodation, adequate provision has been made for many years in the case of all new schools erected according to plans approved by the Scotch Education Department. The department have also, in a memorandum issued in [illegible] their view, ought to be done as regards [illegible] schools. There are, however, a consid [illegible] in which the cloakroom and sanitary accommodation is unsatisfactory, and it appears from the reports of His [illegible] are dilatory and neglige [illegible] I propose, therefore, to [illegible] as regards any of these matters have been observed by the school medical officer, they shall be reported forthwith to His Majesty's inspector for the district, who will, after such further inquiry as he may think necessary, take steps under Article 32 of the Code to require managers to provide the necessary accommodation or to secure the proper cleansing of the schools under penalty of reduction of grant.

The Physical Condition of School Children in England.

In the course of his speech on the Education Estimates in Committee of Supply, [illegible]

Mr. J. A. PEASE (President of [illegible] estimates are largely based on the [illegible] our schools, and it has been cust [illegible] growth in the child population of [illegible] schools. But last year (1911–12) [illegible] school over five years of age increased by only 4030, while those who [illegible] are under five decreased by 20,094—a decr [illegible] children in our schools. The census of 191 [illegible] relating to the six-year-old children in our [illegible] year-old children of to-day. They were fev [illegible] year before—that is to say, instead of there being an increase in the population, there has been an actual decrease of children of school age for that particular year of 846. But that is not all. The statistics of [illegible] s fact, which is, I think, of great [illegible] point, that the birth-rate is steadily [illegible] umber of births was 948,000, in the [illegible] t those dates?—Mr. J. A. PE [illegible] I have only looked into the s [illegible] re has been a diminution, no [illegible] ch is a very material factor in [illegible] age. I may draw the attentior [illegible] nfantile mortality in 1911 was [illegible] 1000. But in regard to school age there is no such diminution in the child mortality as would counterbalance the effect of the diminution in the birth-rate. The total number, therefore, taking a stationary number for our estimates for next year, will be based upon the figures on the registers of last year—6,033,914 children. But those estimates are not only disturbed by the diminution in the birth-rate. They have also been disturbed by the great diminution in the number of children under five years attending our elementary schools. In 1902 there were 613,475 infants between two and five years attending our elementary schools, while in 1912 the number had dropped to 332,866, or a diminution of 280,609 young children, which is a reduction of 45 per cent. in ten years. There is no doubt a natural disposition when a smaller grant is given for children under five and when additional expenditure is placed upon local authorities which has to be met out of the grant, for more attention to be paid to those who attend school in the compulsory ages between 5 and 14 than to smaller children. I am also satisfied from inquiries which I had made that [illegible] hat education which was given in our [illegible] has not been to the interests of the [illegible] m. That is being more and more [illegible] In 1908 one of my predecessors appointed a consultative committee to report on this question, and they reported that if a mother does her duty, if she takes care of her children, if she knows the best way in which to use her narrow means, if she keeps her house clean, if there is a suitable play place for the children, and if the homes are kept well ventilated and decent, there is no better place for these little dots of between three and five than under their mother's care; but if, on the [illegible]

ventilated, where there would be plenty of freedom of movement for the children, constant change in their occupation and opportunities for sleep, and that the teacher should be very carefully selected to look after these children, and in addition to the teachers there should also be attendant nurses. I am glad to say that the parents in this country are getting to understand better than they did how to look after their infant children. At the present moment we have in the country 200 schools for mothers. We have a great number of medical officers who super- [illegible]

Medical Inspection and Treatment.

[illegible]

and the last figures show what a serious amount of illness and trouble there is amongst children of this country at the present time when they first enter the schools. 10 per cent. have their eyesight impaired in some way or other, 5 per cent their hearing, 3 per cent. suffer from ear disease, 5 per cent. from adenoids, 50 per cent. from serious decay of their teeth (in many cases it goes up to 80 or 90 per cent. of decay more or less in degree), tuberculosis 2 per cent., heart disease 2 per cent., and malnutrition 10 per cent. I am glad to say that the authorities who have been comparing their statistics one year with another, find that there is already a real improvement in the condition of the children. The medical officer at Portsmouth informs the Board that the number of those who came to school in 1908 with dirty bodies was 13·8 per cent., but last year it was only 3 per cent. Those who came in a verminous condition in 1908 were actually [illegible] medical [illegible] ust been [illegible] be very [illegible] erest the [illegible] red as a [illegible] dren are [illegible]

very good work is being done. I have been rather better than my word in regard to the contribution which I gave to London and we were able to give the authorities there a grant for the last year of £13,683. In addition to that, London receives a grant of £725 in connexion with the open air schools which have been established by the London County Council, and which are materially beneficial to a certain section of the less robust portion of the school population.

MONDAY, APRIL 14TH.

Amendment of National Insurance Act.

Mr. WORTHINGTON EVANS asked the Prime Minister whether it was intended to introduce the Bill to amend the National Insurance Act before the Whitsuntide adjournment.—Mr. ASQUITH replied: I am not in a position to make any statement on the subject.

Medical Certificates for Sickness Benefit in Ireland.

Sir JOHN LONSDALE asked the Secretary to the Treasury to state in how many counties and county boroughs in Ireland had panels of doctors been formed for the purpose of granting to insured persons the medical certificates which were required before sickness or sanatorium benefit could be obtained, and in how many counties and county boroughs had panels not been formed.—Mr. ROBERTSON (on behalf of Mr. MASTERMAN) answered: I understand from the Irish Insurance Commissioners that names of doctors are still being received and that the question is being considered at the Advisory Committee to-morrow. The Commissioners will communicate with the honourable baronet.

Unqualified Practitioners and the National Insurance Act.

Mr. F. HALL (Dulwich) asked the Secretary to the Treasury whether, under the National Insurance Act, arrangements could only be made with duly qualified medical practitioners for the administration of medical benefit; whether [illegible] second part is in [illegible]

Rural Practitioners and Drug Supplies.

Mr. FITZROY asked the [illegible] in which a medical man [illegible] insured persons, he was [illegible] clause securing to him the right to receive the additional 2s. as provided by the National Insurance Act, and whether he was aware that [illegible] Committee.

Sleeping Sickness in Rhodesia.

Dr. CHAPPLE asked the Secretary of State for the Colonies whether he had received any details of the spread of sleeping sickness in [illegible] of removal.

TUESDAY, APRIL 15TH.

South Shields Panel.

[illegible] Act guaranteeing free ch[illegible] posed to do in the matte[illegible] been caused by this [illegible] Mr MASTERMAN) replied[illegible] tion referred to in the [illegible] *Local Medical Committ*[illegible] on the panel present [illegible] but the Insurance Com[illegible] I may point out that [illegible] persons who have [illegible] have been refused [illegible] if it were adopted, [illegible] ting more than 800 [illegible]

Approved Societies and Medical Men.

Mr. WATT asked the Secretary to the Treasury whether it was [illegible]

Mr. ROBERTSON (who replied) said: The answer to the first part of the question is in the negative Medical benefit is administered by Insurance Committees and not by Approved Societies. With regard to the second part, persons who are allowed by Insurance Committees to make their own arrangements for medical attendance and treatment will receive contributions from [illegible] attendance and treatment. [illegible] which there has never, so f[illegible] suggested in the third part [illegible] that I fully understand fro[illegible] arrangements my honourable friend has in mind. Perhaps he would furnish me with further details.

Scottish Clerks' Association and Medical Benefit.

Mr. WATT asked the Secretary to the Treasury whether his depart[illegible] that department on Oct. 31st, [illegible] the effect that members of [illegible] making their own arrange- [illegible] so, and that the committee [illegible] which medical benefit was [illegible] treatment.— [illegible] d: It is pro- [illegible] sition of the [illegible] er referred to [illegible] the Associa- [illegible]

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of a vacancy for a Certifying Surgeon under the Factory and Workshop Acts at Portree, in the county of Inverness.

Births, Marriages, and Deaths.

BIRTHS.

GRAVES.—On April 8th, at Lusmagh Lodge, Clevedon, Somerset, the wife of R. K. G. Graves, M.R.C.S., L.R.C.P. Lond., of a son.

WILLIAMSON.—On April 7th, at The Limes, Epsom, the wife of John Williamson, M.D., of a son.

MARRIAGES.

OSBORNE—DENMAN.—On April 8th, at the Bolton Memorial Church, Oakamoor, by the father of the bride, Staff-Surgeon Richard Sidney Osborne, R.N., to Alice Campbell, eldest daughter of the Rev. Charles Denman and Mrs. Denman.

RAMSAY—ILLINGWORTH.—On April 9th, at St. James's, Blackburn, Jeffrey Ramsay, M.D., to Alice, eldest daughter of Walter Illingworth, of The Woodlands, Blackburn.

DEATHS.

IMAGE.—On April 8th, at St. Margaret's, Bury St. Edmunds, Francis Edward Image, M.A., M.B. Cantab., M.R C.S. Eng., aged 70 years.

McDONALD.—On April 8th, at Charlton House, Shepperton-on-Thames, George B. McDonald, M.D., J.P., aged 71 years.

STIRLING.—On April 13th, at Belfield Lodge, Fallowfield, Manchester, Elizabeth Ferguson, wife of William Stirling, M.D., Professor of Physiology, Victoria University of Manchester.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

HEALTH MATTERS IN THE FEDERATED MALAY STATES.

REPORTS on the affairs of the Federated Malay States (Pérak, Selángor, Negri Sembilan, and Pahang) and of the Feudatory Malay States (Kelantan, Trengganu, Kedah, and Perlis) have just been presented to both Houses of Parliament by command of the King. The Federated States are situated on the mainland of the Malay Peninsula and are closely connected with the Straits Settlements. The total area of the Federation is 27,506 square miles, with a population in 1911 of 1,036,999. In regard to the Feudatory States, Kelantan, on the east coast of the Malay Peninsula, has a total length of about 120 miles and a breadth of 50 miles; the population is 286,751. Trengganu lies south of Kelantan, is of approximately similar dimensions and area to that state, and has a population of 154,000. Kedah is an ancient Mahommedan State on the West Coast of the Peninsula, with a group of islands in the Straits of Malacca, the total population being about 245,000. Perlis is a smaller State on the west coast with a population of only 32,740. All these States, both federated and feudatory, are now administered under the supervision of British advisers, with the Governor of the Straits Settlements (Sir A. H. Young, K.C.M.G.) as High Commissioner. The medical section of the report on the four federated states mentions that the year 1911 was in general a very unhealthy one. The death-rate was 37·03 per 1000, as compared with 32·16 in 1910. The birth-rate was 19·41, as compared with 21·39 in 1910. There were 97,162 admissions to hospital, the death-rate among patients being 9·57. The number of out-patients who sought treatment was 232,506, being about 15,000 more than in 1910. Malaria was the cause of 45 per cent. of the deaths, with a mortality rate of 16·39 per 1000 of the population. Dysentery and diarrhœa accounted for 19 per cent. of the total number of deaths. Beri-beri was the cause of 695 deaths, there being a slight decrease in Perak, but an increase in Selangor and Negri Sembilan. Outbreaks of cholera occurred in Lower Perak and in Krian, in the lunatic asylum at Taiping, and at Bernam in Selangor. The total number of cases was 683 and deaths 496. Small-pox, formerly the scourge of the Malay Kampongs, accounted for 288 cases and 43 deaths. Ten cases of blackwater fever, with three deaths, were recorded. Four deaths from plague were verified. The total number of vaccinations was 108,121. Malaria has engaged the constant attention of all medical officers. The disease was certainly more prevalent in 1911, and, as the principal medical officer considers, the mortality figures do not alone convey a full knowledge of the amount of harm caused by this disease. A Central Advisory Board has been appointed for the purpose of collecting and distributing information regarding malaria and advising generally on antimalarial measures.

At the Institute for Medical Research further work has been done with a view to the isolation and determination of the substance of high physiological importance contained in rice "polishings," but it is not considered possible at present to estimate the scientific value of these researches. Dr. H. Fraser, the director of the institute, reports that it is satisfactory to find that the conclusions arrived at as to beri beri have received confirmation by investigators in most of the countries where this disease occurs, and that it may now be considered as beyond dispute (1) that among people whose staple diet is rice beri-beri is caused by the continuous consumption of polished rice, and may be prevented by the substitution of unpolished rice; (2) that a harmless rice becomes a harmful one when cooked by steam under pressure. He adds that a further outcome of these researches has been to demonstrate the inefficiency of the methods by which dietetic values have hitherto been determined. Special attention has been devoted by the staff of the institute to anopheline mosquitoes, the distribution of the species and their relative efficiency as malaria carriers, with a view to obtaining accurate knowledge of the factors concerned in the spread of malaria.

The report from the Feudatory State of Kedah states that the year 1911 was marked by the occurrence of a long-continued drought and a severe and prolonged cholera epidemic in consequence. There were recorded altogether 1111 cases of the disease and 886 deaths. 151 cases were treated in the Alor Star Hospital, with 83 deaths. Cholera generally starts in Alor Star, and is due to the lack of good drinking water in the dry season. Steps are being taken to provide a water-supply from hills, but any scheme of this kind will be very costly. In the meantime, as a temporary measure, a rain catchment area has been erected at Alor Star of corrugated iron, draining into large tanks. These tanks are supposed to hold enough to supply drinking water to the town during a two months' drought. During the epidemic referred to drinking water was brought from Penang in tongkangs and sold at Alor Star, and the introduction of the Penang water was instantly followed by a decrease in the number of cases in Alor Star. In addition to cholera there was a slight outbreak of small pox on the coast There were 162 cases and 41 deaths Kedah is well vaccinated, and so the disease did not spread far Apart from cholera and small pox the State was healthy enough 33 per cent of the recorded deaths were due to fever and 19 2 per cent to bowel complaints (excluding cholera) The total number of Malay deaths (exclusive of cholera) was 2861 and of Malay births 2963, showing a slight increase in favour of births In the case of all other nationalities the deaths exceeded the births There were 2293 admissions into all the hospitals with 256 deaths, including cholera patients 21,324 patients were treated at the outdoor dispensaries Dr H S Sugars was appointed medical officer for South Kedah and stationed at Kulim, where it is intended to build a commodious and up to-date hospital, but his duties include those of assistant superintendent of Indian immigrants, and necessitate his absence from his headquarters at Kulim for a great part of each month As compared with the Straits Settlements or the Federated Malay States, the medical staff and hospital accommodation are still very inadequate, but much has been done during the last four years when the state of things existing previously is remembered The report of the British adviser in Perlis shows that in that State 563 cases of cholera were reported with 484 deaths At the dispensary there were 1336 attendances for medical treatment, the principal ailments being malaria (20 cases), venereal diseases (121 cases), dysentery (54), rheumatism (110) skin diseases (222), and bronchial diseases (70) There were 1056 vaccinations, of which 1010 were successful

According to the medical report from the State of Kelantan the number of in patients admitted to the hospital was 376, and there were 24 deaths The out patients treated at the Government dispensary numbered 6793 Of these 3393 were Malays and it is remarked that the popularity of European treatment among the Kelantan Malays is steadily increasing There were 457 patients treated for venereal diseases as compared with 264 in the preceding year. This increase is due to a wider knowledge of the advantages of treatment rather than to an actual increase in the amount of disease, but the residency surgeon *mentions* that these diseases are very prevalent in Kelantan, especially among the youth of both sexes in the town of Kota Bharu As in previous years Kota Bharu was comparatively free from malaria, but the disease prevailed in the up-country districts, and the Government staff at Batu Mengkebang suffered severely Quinine was freely distributed No case of beri beri and only one of small pox occurred during the year The absence of beri beri is attributed to the fact that local rice is almost the only rice consumed in Kelantan, even by the Chinese coolies on the estates There was no definite epidemic of cholera but several deaths were caused by a fatal type of epidemic diarrhœa which broke out in the middle of the year Precautions were taken as if for cholera, and the disease did not spread There were 3793 vaccinations performed by the Government medical staff and 976 by the Duff Development Company's medical officer, most of the latter being estate coolies Buffalo calf lymph obtained direct from the Pasteur Institute at Saigon was used in all cases The Duff Development Company continued to maintain their hospital with 70 beds at Kuala Lebir in charge of Dr A G H Smart, and this *hospital was not confined to the employees of the company* There were 1066 patients, including 24 Europeans, admitted to this hospital during the year, 702 of these being persons employed by the company Hospitals were also maintained on all the other estates The residency surgeon estimates the mortality among the estate coolies at 7 per cent Too much reliance must not be placed on this figure as, though the number of deaths is known, the number of coolies is constantly varying

The report from the State of Trengganu contains no special reference to medical matters

"THE RISING OF THE LIGHTS"

To the Editor of THE LANCET

SIR,—In my letter to you of the 12th inst I omitted to emphasise the fact that when my East London patients spoke of "*rising*" their lights, they undoubtedly meant "*raising*" them The most common phrase was "I keep on 'risin'' my lights" This of course only shows that some of those who use these words mean that they are spitting up their lungs and throws no light on the historical origin of the phrase in question

I am, Sir, yours faithfully,

London, April 13th, 1913 H BRYAN DONKIN.

THE IMPERIAL CADET ASSOCIATION

THE Imperial Cadet Association and "Lord Roberts's Boys," of which Lord Roberts is president, was established with the fourfold object of training the youth of the country in discipline, drill and the use of the rifle, of paving the way for a State aided and State-supervised uniform and universal system of cadet training for all boys physically fit from the age of 12 years upwards of providing and equipping rifle ranges in public elementary schools, and of encouraging home cadets to use the facilities provided by the nation for employment and continued and technical education Incidentally the youth themselves are benefited by the formation of character a true spirit of citizenship and patriotism is fostered and the foundation is laid for the ultimate solution of the problem of national defence Subscriptions to the general fund are needed for general training in the City of London, the annual summer camp, and for extending Imperial hospitality to cadet guests from overseas The practice of return visits as when Canada and New Zealand sent cadets last year to England and British cadets were sent to Canada last August, undoubtedly increases the conception of the solidarity of the Empire and binds closer the ties uniting the Mother Country and her dominions overseas The honorary secretary is Dr. Reginald J L Hanson, 5, Harley-street, W, and the treasurers, to whom subscriptions may be sent, are the Hon Herbert Gibbs and Mr. E O. Ouvry, 10, Little College street, Westminster, S W.

DANDRUFF

To the Editor of THE LANCET

SIR,—1 Can you give me any suggestion for the treatment of a young lady who has been troubled with dandruff for years and more recently the hair is found to split very much and to come out easily? Frequent brushing and washing with carbonate of potassium has been done A spirit-and water lotion, equal parts, with a small quantity of sublimate and some resorcin has been used 2 Can you give any references to literature, and especially to a concise book?

I am, Sir, yours faithfully,

April 8th 1913 J T (M D)

*** 1 The condition of seborrhœa from which the patient appears to be suffering may be treated by applications Frequent washing is undesirable, if the hair is washed every two or three weeks it will be sufficient The application may take the form of a lotion, which is much more pleasant than an ointment, though the latter is often more effective A lotion which is often useful is —

Formalin	ʒss
Spiritus vini rect	℥iv.
Ol olivæ	ʒii
Resorcin	gr x.
Aq ad	℥viii.

Various modifications of this lotion may be required according to the actual condition of the patient upon which much depends 2 Most of the treatises on diseases of the skin contain chapters on the treatment of seborrhœa —ED L

A NEW PRACTITIONER'S RECORD BOOK.

THE *Medical Practitioner's Desk Companion*, which has been submitted to us by *Robert Gibson and Sons, Limited, of Glasgow*, consists practically of a visiting list ruled for name and address, with daily attendance columns for a month to the open page, charges, cash received, folio reference, total attendances and visits age and sex, occupation, and illness columns These pages are indexed for each month of the year with the entire alphabet, so that any patient's monthly record may be easily found At the end of each month are two pages ruled for engagements and an analysis page for summarising the total number of attendances in each month, quarter, and the year, and also the total number of patients, male and female respectively The book is essentially a desk book, for though small and compact it is too bulky for the pocket It is possible that the analysis pages may be of some service to practitioners on the panel in estimating the amount of work entailed by the Insurance Act and its *pro rata* remuneration

THE DEVELOPMENT OF A CHEMICAL INDUSTRY.

A VERY interesting story of the growth of a great industry is presented in a souvenir, printed and published by Messrs Meister, Lucius, and Brüning, commemorating the jubilee of the foundation of their works at Hoechst on the Maine The first page shows a small factory on the banks of the river, snugly situated amongst sylvan surroundings Then follow illustrations of plans of the great "farbwerke," showing the allocation of spaces to the various departments of the business—acid works, alizarin house, alkaloid laboratories, and a section devoted to bacteriology and the preparation of serums The final scene is an immense area covered with factories the activities of which are illustrated by a forest of smoking shafts The book is very artistically got up, *is printed in bold type, and copiously illustrated*

COMMUNICATIONS not noticed in our present issue will receive attention in our next

---

The following journals, magazines, &c, have been received:— Biochemical Journal, Journal of Comparative Pathology and Therapeutics, Journal of Anatomy and Physiology, Bulletin of Johns Hopkins Hospital, South African Medical *Record*, Revue de Médecine, Revue de Chirurgie, Brain, British Journal of *Dermatology*, Journal of Hygiene, Archives of Roentgen Rays St Paul Medical Journal, Canadian Journal of Medicine and Surgery, Guy's Hospital Gazette, American Journal of Surgery, Eugenics Review, La Clinique Ophthalmologique

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

THURSDAY.—Mr. A. G. Huntsman: (1) Protostigmata in Ascidians (communicated by Prof. A. B. Macallum); (2) On the Origin of the Ascidian Mouth (communicated by Prof. A. B. Macallum).—Mr. F. A. Bainbridge, Mr. S. H. Collins, and Mr. J. A. Menzies: Experiments on the Kidneys of the Frog (communicated by Dr. C. J. Martin).—Mr. C. Revis: (1) On the Probable Value to Bacilli Coli of "Slime" Formation in Soils (communicated by Sir J. R. Bradford, secretary to the Royal Society); (2) Variation in Bacillus Coli—the Production of Two Permanent Varieties from One Original Strain by Means of Brilliant Green (communicated by Sir J. R. Bradford).

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY.

SPECIAL MEETING OF FELLOWS OF THE SOCIETY: at 5 P.M.

Discussion:

On Alimentary Toxæmia: its Sources, Consequences, and Treatment. (Third Meeting.)

The discussion will be re-opened by Mr. Lockhart Mummery and continued by Prof. Arthur Keith, F.R.S., Dr. W. Langdon Brown, Mr. George Rowell, Mr E. M. Corner, Mr. Peter Daniel, Mr. C. H. Fagge, Mr. H. W. Carson, Mr. K. W. Goadby, Mr. E. C. Hughes, and Mr. Macleod Yearsley.

The Fourth Meeting will be held on Monday, April 28th, at 5 P.M., when the discussion will be re-opened by Dr. William Hunter.

TUESDAY.

SECTION OF MEDICINE (Hon. Secretaries—Robert Hutchison, H. Batty Shaw): at 5.30 P.M.

Papers:

Dr. Lyon Smith: Gout and Chronic Rheumatism: Their Ætiology from the Bacteriological Standpoint, and Some Notes on Treatment.

Dr. T. D. Lister: Ambulatory Treatment by means of Tuberculin.

FRIDAY.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN (Hon. Secretaries—H. S. Clogg, F. Langmead, P. N. Blake-Odgers): at 4.30 P.M.

Cases:

Dr. Bunch: Baby with Congenital Syphilis Cured by Intravenous Injection of "606."

Mr. Anglin Whitelocke: (1) Family of Five Children, all with Thyroid Enlargement; (2) Successful Case of Cerebral Decompression for Convulsions, Jacksonian in Type, in a Child of 4.

Dr. Porter Parkinson: Two Cases of Tuberculous Kidney.

Mr. Fitzwilliams: Tumour Removed from Capsule of Shoulder Joint.

Dr. Zundel: Diabetes Insipidus Associated with Infantilism.

Dr. Cockayne: Distal Myopathy.

Specimen:

Dr. J. D. Rolleston: *Diphtheria of Œsophagus.*

Communications:

Mr. Anglin Whitelocke: (1) Successful Operation for Strangulated Hernia in an Infant 18 Days Old; (2) Case Simulating Meningitis in which the Symptoms were caused by the Escape of Thread Worms into the Peritoneal Cavity through a Perforated Appendix.

SECTION OF EPIDEMIOLOGY AND STATE MEDICINE (Hon. Secretaries—G. S. Buchanan, William Butler): at 8.30 P.M.

Dr. T. Shadick Higgins: The Diphtheria Bacillus and Scarlatinal Infection.

Surgeon McCowen, R.N. (contributed [illegible] Bassett-Smith, C.B., R.N.): A Not [illegible] Principe Island and Angola, West [illegible]

ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.

MONDAY.—8 P.M., Dr. D. Sommerville: Antiseptics and Disinfectants:—I., Historical and General. (Cantor Lecture.)

MEDICO-LEGAL SOCIETY, 11, Chandos-street, Cavendish-square, W.

TUESDAY.—8.30 P.M., Paper:—Dr. W. A. Brend: The Futility of the Coroner's Inquest.

HUNTERIAN SOCIETY.

WEDNESDAY.—8.30 P.M., Annual Meeting. 9 P.M., Hunterian Medallist.

HARVEIAN SOCIETY OF LONDON, Stafford Rooms, Titchborne-street, Edgware-road, W.

THURSDAY.—8.30 P.M., Paper.—Dr. T. J. Horder: Infections Due to the Bacillus Coli.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM, 1, Wimpole-street, W.

THURSDAY.—10.30 A.M. to 12.30 P.M., Papers:—Mr. F. Juler: Acute Purulent Keratitis in Exophthalmic Goitre treated by Repeated Tarsorrhaphy.—Mr. Ormond: Two Cases of Permanent Hemianopia following Migraine.—Dr. Taylor and Dr. G. Holmes: (1) Conditions Present in Several Members of a Family with Hereditary Optic Atrophy; (2) Unusual Conditions associated with Optic Atrophy of the Family Type.—Mr. B. Harman: (1) An Analysis of 250 Cases of High Myopia; (2) A Suggestion for the Grading of [illegible] .30 P.M. to 4.30 P.M.—Papers:—Mr. A[illegible] the Excision of the Conjunctival [illegible] Dorrell: Sensory Reflex in Tobacco Amblyopia.—Mr. T. Collins and Mr. Hudson: On the Pathological Examination of an Eye with Congenital Anterior Staphyloma.—Mr. T. Collins: Visible Vessels on the Surface of the Iris. Annual Business Meeting at the conclusion of Afternoon Meeting.

FRIDAY.—10.30 A.M. to 12.30 P.M., Discussion on Vascular and Other Retinal Changes in Association with General Disease (opened by Dr. J. Taylor, Dr. L. Werner, and Mr. G. Coats). 2.30 P.M. (at the Royal London Ophthalmic Hospital, City-road, E.C.), Cases:—Mr. A. Macnab: An Early Case of Chronic Glaucoma Operated on by Trephining in which there was subsequently a Diminution in the Excavation of the Disc.—Mr. T. Collins: A Case of Buphthalmos with Full Vision and Without any Cupping of the Optic Disc.—Mr. Ormond: (1) Thrombosis of the Retinal Veins, shown at a meeting of the Ophthalmological Society in October, 1906; (2) Case of Albuminuric Retinitis of 10 Years' Standing.—Mr. Lawford: Vascular and Retinal Changes resulting from Partial Venous Thrombosis. (A discussion will follow the examination of the cases.)——An Exhibition of Ophthalmic Instruments, &c., will be held during the days of the meetings at the Rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, W., to which all members are invited.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

MONDAY.—5 P.M., Mr. Shattock: Specimens illustrating Atrophy. (Museum Demonstration.)

FRIDAY.—5 P.M., Prof. Keith: Specimens illustrating Congenital and Acquired Deformities of the Spine. (Museum Demonstration.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. E. G. Little: Clinique (Skin). 5.15 P.M., Lecture:—Mr. H. Grimsdale: On the Differential Diagnosis of Glaucoma.

TUESDAY.—4 P.M., Dr. J. Collier: Clinique (Medical). 5.15 P.M., Lecture:—Dr. J. Donelan: Some Common Throat and Nose Disorders.

WEDNESDAY.—4 P.M., Mr. H. A. T. Fairbank: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. C. R. Box: Pellagra.

THURSDAY.—4 P.M., Dr. T. G. Stewart [illegible] 5.15 P.M., Lecture:—Dr. O. K. Williamson: [illegible] an Explanation of Certain Cases [illegible] Monoplegia.

FRIDAY.—4 P.M., Mr. J. D. Grant: Clinique (Ear, Nose, and Throat). 5.15 P.M., Lecture:—Dr. W. Wingrave: Tonsils.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Diseases of Women. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., [illegible]

TUESDAY.—10 A.M., Gynæcological Operations. [illegible] and Surgical Clinics. X Rays. Operations. Diseases of the Throat, Nose, and Ear. 2.30 P.M., Diseases of the Skin.

WEDNESDAY.—10 A.M., Diseases of Children. Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Diseases of the Eye. Diseases of Women.

THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Operations. Orthopædics. 2.30 P.M., Diseases of the Eye.

FRIDAY.—10 A.M., Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Diseases of the Throat, Nose, and Ear. 2.30 P.M., Diseases of the Skin.

SATURDAY.—10 A.M., Diseases of Children. Operations of the Throat, Nose, and Ear. Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—Out-patient Demonstrations:—10 A.M. Dr. Singer: Medical. Mr. H. Curtis: Surgical. 12 noon, Mr. G. N. Biggs: Throat, Nose, and Ear.——2.15 P.M., Mr. W. Turner: Surgery. 3 P.M., Mr. W. Turner: Operations. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4.15 P.M., Mr. R. Lake: Ear and Throat.

TUESDAY.—Out-patient Demonstrations:—10 A.M., Dr. G. Holmes: Medical. Mr. Cole: Surgical. 12 noon, Dr. H. MacCormac: Skin.——2 P.M., Mr. L. McGavin: Operations. 2.15 P.M., Mr R. Carling: Surgery. 3.15 P.M., Dr. G. Rankin: Medicine. 4.30 P.M., Special Lecture:—Sir Wm. Bennett, K.C.V.O.: Remarks on Some Instructive Surgical Cases.

WEDNESDAY.—Out-patient Demonstrations: 10 A.M., Dr. F. [illegible]mead: Medical. [illegible] Surgical. 11 A.M., Mr. R. E. Bickerton: Eye.——2 P.M., Mr. L. V. Cargill or Mr. Choyce: Operations. Dr. A. Davies: Pathological Demonstration. 2.15 P.M., Dr. F. Taylor: Medicine. 3.15 P.M., Mr. Cargill: Eye Clinique. 4.30 P.M., Mr. C. C. Choyce: Surgery. 3.15 P.M., Special Lecture:—Mr. L. V. Cargill: The Determination of Visual Acuity, Diagnosis of Refraction Errors, and Detection of Malingering.

THURSDAY.—Out-patient Demonstrations:—10 A.M., Dr. Singer: Medical. Mr. H. Curtis: Surgical. 12 noon, Mr. G. N. Biggs: Throat, Nose, and Ear.——2 P.M., Mr. R. Carling or Mr. W. Turner: Operations. 3.15 P.M., Dr. R. Wells: Medicine. 4.30 P.M., Special Lecture:—Mr. H. Curtis: Fractures.

FRIDAY.—Out-patient Demonstrations:—10 A.M., Dr. G. Holmes: Medical. Mr. Cole: Surgical. 12 noon, Dr. H. MacCormac: Skin.——2 P.M., Mr. L. McGavin: Operations. 2.15 P.M., Sir John Rose Bradford: Medicine 3.15 P.M., Mr. L. McGavin: Surgery.

SATURDAY.—Out-patient Demonstrations: 10 A.M., Dr. F. Langmead: Medical. [illegible] Surgical. 11 A.M., Mr. R. E. Bickerton: Eye.—10 A.M., Radiography.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, E.C.

Course of Lecture-Demonstrations on Diseases of the Chest, with Special Reference to Tuberculosis (including a Tuberculin Course):—

MONDAY.—4.30 P.M., Dr. B. King.
THURSDAY.—4.30 P.M., Dr. P. B. Ridge.
FRIDAY.—3 30 P.M., Dr. Kellie.

QUEEN'S HOSPITAL FOR CHILDREN, Board Room of the Hospital, Hackney-road, N.E.

THURSDAY.—4 P.M., Mr. S. Stephenson: The Common Eye Disease of Childhood—Phlyctenulosis.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.

THURSDAY.—6 P.M., Dr. W. Griffith: Eczema and its Treatment.

ROYAL INSTITUTION OF GREAT BRITAIN, Albemarle-street, Piccadilly, W.

TUESDAY.—3 P.M., Prof. W. Bateson: The Heredity of Sex and some Cognate Problems. (Lecture II.)

ROYAL SANITARY INSTITUTE, 90, Buckingham Palace road, S.W

WEDNESDAY.—5 P.M., Dr. C. W. Daniels: Insect Carried Diseases and their Prevention. 6 P.M., *Display of Micro-cinematograph Films.*

ANCOATS HOSPITAL, Manchester.

THURSDAY.—4.15 P.M., A Demonstration of Medical and Surgical Cases will be given by the Members of the Honorary Staff. (Post-Graduate Clinic.)

ROTUNDA HOSPITAL POST-GRADUATE COURSES, Dublin.

MONDAY.—10 A.M., Obstetrical Lecture: Mechanical Obstructions to Labour (continued). 11 A.M., Examination of Patients and Minor Operations.
TUESDAY.—10 A.M., Major Operations. 4 P.M., Class in Gynæcological Diagnosis.
WEDNESDAY.—10 A.M., Obstetrical Lecture: The Rarer Forms of [illegible]

[illegible]

For further particulars of the above Lectures, &c., see Advertisement Pages.

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced:—

April 22nd–25th (London L.C.C. Technical Institute, Vincent-square).—Annual Nursing and Midwifery Conference.
„ 26th–Nov. 5th (Ghent).—International Exhibition.
May 15th–18th (Paris).—Twenty-first Annual Congress of the Royal Institute of Public Health.
[illegible]
J [illegible]
Institutions.
July 7th–12th (Exeter).—Twenty-eighth Congress of the Royal Sanitary Institute.
„ 16th–18th (Oxford, Keble College).—Oxford Ophthalmological Congress.
„ 22nd–25th (Brighton).—Eighty-first Annual Meeting of the British Medical Association.
Aug. 1st–3rd (Ghent).—Congress against the Adulteration and [illegible]
„ [illegible]
„ [illegible]
„ 20th–26th (Ghent).—Third International Congress of Neurology and Psychiatry.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of *THE LANCET should* be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to *THE LANCET Offices, will ensure regularity in the despatch* of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—MESSRS. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

Y.—Dr. G. Young, Liscard.

The Hunterian Lectures

ON THE

PRINCIPLES AND TECHNIQUE OF THE OPERATIVE TREATMENT OF MALIGNANT DISEASE OF THE MOUTH AND PHARYNX.

Delivered before the Royal College of Surgeons of England on March 3rd and 5th, 1913,

By WILFRED TROTTER, M.S. Lond., F.R.C.S. Eng.,

ASSISTANT SURGEON, UNIVERSITY COLLEGE HOSPITAL.

LECTURE II.[1]

Delivered on March 5th.

Mr. President and Gentlemen,—So far we have dealt entirely with problems connected with the cure of the disease, and have laid down the conditions which must be satisfied if cure is to be attained with any certainty. We now have to ask whether the technique at our disposal allows us to meet these requirements with a reasonable degree of safety to the patient. This chapter of the subject is concerned almost entirely with the infective complications of the operation. The primary operative risks, such as shock, hæmorrhage, and mechanical respiratory troubles, are so uncommon or so completely met by ordinary surgical measures that we need not consider them here.

The Dangers of the Operation.

The infective complications dangerous to life can be divided into two main classes: pulmonary infections and wound infections. Both of these are common and constant dangers in connexion with operations on the mouth; they are much more serious in operations on the pharynx.

I. LUNG COMPLICATIONS.

That these still constitute a serious danger cannot be doubted, though it is perhaps sometimes thought that they are greatly less frequent than formerly.

Septic pneumonia is the essential condition met with. It is particularly likely to lead to suppuration, with the formation of single or multiple abscess cavities with gangrenous walls. The pus from these has the same smell as an ulcerating epithelioma and all abscesses derived from the mouth and pharynx. The pneumonia is particularly fatal, and though I believe I have seen a few cases which have recovered, as a general rule the diagnosis brings with it the certainty of a fatal termination. Possibly operation on some of these cases of localised gangrene may be able to save a few. Two cases of post-operative gangrene of the lung in which I laid open the gangrenous focus were somewhat encouraging. In one, not, however, a mouth or throat case, the patient recovered; in the other the lung cleared up rapidly, but the patient died from a pyæmic focus elsewhere.

The causation of these pneumonias is a somewhat complex interaction of various factors, but a study of the evidence over a large number of cases and the effect of various prophylactic measures show that there are three processes at work. 1. The infection is derived from general sepsis of the mouth and from the septic ulceration of the growth. The extent of the ulceration is greatly influenced by the sepsis in the mouth, whether the growth is in the mouth or pharynx. 2. The lungs are irritated by the anæsthetic vapour and by blood. Probably the actual irritating material is mucus in which the anæsthetic is dissolved. The importance of the entry of blood alone has probably been greatly exaggerated. 3. The infective material is conveyed to the lungs by aspiration during the operation. Aspiration is favoured by any kind of respiratory obstruction.

There is one other mechanism I have omitted in this enumeration because it can be so easily and should be so rigidly excluded. This is the indiscriminate mopping out of the mouth and pharynx on account of the supposed necessities of the anæsthetist. It should on no account be allowed except under the most careful precautions, for by its means gross quantities of septic material are apt to be conveyed from the ulcer to the upper opening of the larynx, whence they are promptly aspirated into the lungs. In the few moments that elapse before the windpipe is opened it is scarcely ever necessary to sponge out the throat at all.

The importance of the different factors enumerated can be inferred from various clinical observations. In edentulous patients with but slightly ulcerated tumours pneumonia is scarcely to be feared. Accidental leakage past the pharynx or larynx plug during the operation is extremely dangerous. The influence of the anæsthetic is probably the least important factor. It is perhaps to it that the increase in the incidence of pneumonia with the length of operations is due. This increase is, however, seen only if the other factors are acting also. Short anæsthetics, even though all the other conditions are unfavourable, are very rarely followed by pneumonia.

The relative unimportance of entry of blood is shown by the occurrence of pneumonia after gland operations which are done before the primary growth is removed. These long and difficult operations are usually accompanied by great difficulty in maintaining a free airway and consequent excessive aspiration at the laryngeal opening. This is a strong argument against the gland operation being done first in cases with much ulceration.

The one precaution against pneumonia which I have found to be efficient is opening the larynx or treachea and plugging the airway higher up. I use it invariably for all cases except the smallest growths on the anterior part of the tongue. I find I have done a preliminary laryngotomy or tracheotomy more than 50 times. I have never seen any harm whatever come from it, and, on the contrary, a deal of good. Its advantages are numerous in addition to minimising the incidence of pneumonia: (*a*) The patient can be kept absolutely tranquil, breathing without effort and without coughing, so that the shock of the operation is greatly diminished by the absence of these dangerous and exhausting exercises. (*b*) It solves all difficulties of the anæsthetic. For these patients chloroform given through a laryngotomy tube is as nearly a perfect anæsthetic as we possess. (*c*) It greatly diminishes the risk of pneumonia. I have come to regard the gland operation done as a first stage as much more dangerous than the primary growth operation. In certain bad cases where the gland operation had to be done first I have done a preliminary laryngotomy and been much encouraged by the result. (*d*) It allows the complex operations of modern technique to be done deliberately and with the attention to detail they demand.

The procedure has no disadvantages. Laryngotomy, which should be reserved chiefly for mouth operations, can be done through a mere puncture which leaves an invisible scar, and takes three or four minutes. Tracheotomy should be used whenever the tube may have to be left in for some time. It takes a few minutes longer but is always quite easy. An interesting phenomenon is often observed in these cases, and that is the occurrence of periodic respiration after the tube has been put in and the preliminary apnœa has passed off. It is common in elderly patients and has no serious significance.

One important caution may be added, and that is that if there is the least reason to suspect any trouble whatever in breathing during the immediate post-operative period the tube should be left in. It can do no harm and may save the patient's life, as the shock of an attack of even partial asphyxia is very apt to be fatal in an enfeebled patient.

II. WOUND INFECTION.

This is little likely to be dangerous in the mouth, but immediately the anterior faucial pillars are passed the danger becomes a very serious one.

Acute septicæmia is not uncommon with large wounds of the pharynx. It generally begins at once and destroys the patient within a few days of the operation. Cellulitis is most serious with wounds low down in the pharynx. Wound infection from the mouth has certain marked and constant characteristics and tends to run a very definite course. All wounds which are allowed to come into contact with pharyngeal or oral mucus undergo necrosis of the surface with the formation of a definite slough. If the surface is quite open the infection does not tend to spread. The temperature is raised slightly and remains up for about a week, when separation of the sloughs with free suppuration therefore we have other series of experiments with preparations of staphylococci, coli, &c.

---

[1] Lecture I. was published in The Lancet of April 19th, 1913, p. 1075.

According to Manouélian atheromatous plaques appeared in the aortæ of a large proportion of rabbits inoculated repeatedly with staphylococci (in 73 out of 86) and also in monkeys. These plaques occurred at the level of the arch of the aorta. It must be noted, however, that Weinberg found spontaneous atheroma in 4–19 per cent. of rabbits. More recently Bertrand and Berthelot have isolated from the fæces of patients suffering from chronic autointoxication an organism which when grown on a special medium containing histidine yields a highly toxic product apparently identical with β-imidazolethylamine, a base previously obtained by Ackermann in the putrefaction of histidine and also by Barger and Dale in ergot. The organism which yielded this toxic product belonged to the coliform group, and according to the authors was closely related biochemically to the B. lactis aerogenes. The authors make the statement that this particular organism was never found in the fæces of normal healthy people. This is a very important statement, and confirmation must be awaited before it can be accepted.

Turning now to the animal experiments performed with definite chemical substances which are understood to arise from the action of micro-organisms in the intestinal tract. In these experiments by Metchnikoff, Dratschinski, and others potassium phenylsulphate and indol have been the chief substances whose toxic action on animals has been investigated. With potassium phenylsulphate atheromatous changes in the aorta of rabbits, guinea-pigs, and monkeys were produced and small cell infiltrates in the liver and kidney. Rabbits received by the mouth 0·04 grm. of paracresol during a period of 1–4 months, and 61 per cent. of the rabbits showed atheromatous plaques. Dratschinski gave similar doses of indol daily to guinea-pigs by the mouth, and obtained evidence of atheromatous degeneration of the wall of the aorta, with chronic interstitial processes in the organs, such as the liver, kidney, and suprarenal capsules. These foci in the wall of the aorta invariably contained calcareous deposits, and the question to be decided was whether these foci met with in the animals intoxicated with indol were merely further stages in the development of the cartilaginous foci met with in similar situations in normal guinea-pigs, especially those of advanced age. Such foci were met with in 67·5 per cent. of normal guinea-pigs weighing 250 grm. and over. The author was of opinion that hyaline and calcareous foci encountered in the intoxicated animals were distinct from the cartilaginous foci found in normal animals, and concluded that intoxication with indol was the exciting cause. It does not appear to me, however, at all proven that the indol, if it affected anything at all, did any more than hasten the calcareous transformation of these normal cartilaginous foci, and the question of the influence of indol in this connexion must still be considered as undecided.

I now come finally to discuss the changes which have been stated to occur in the composition of the intestinal flora in cases of intestinal stasis and in cases which have suffered resection of the large intestine. This question has recently been attacked by Distaso, who had the advantage of obtaining material from Mr. Arbuthnot Lane's cases. Distaso roughly classifies the organisms of the intestinal tract according as they do or do not produce indol. In the normal adult man the fæces, as is well known, show a preponderance of indologenic organisms of the coliform group. In constipation, according to Distaso, there are practically no Gram-negative organisms, but there is a great abundance of spores, the indol-formers being now of the sporulating type. There is also an absolute diminution in the quantity of bacilli present. The conclusion drawn by Distaso that the flora of constipation is an index of intoxication is entirely unsupported by the evidence he adduces. In cases operated upon for removal of the large intestine it was observed that the flora showed not so much a qualitative change as a quantitative change, with a consequent alteration in the functional activity of the organisms concerned. Before operation the flora was one typical of constipation, while after operation the indologenic organisms had largely given place to the acetogenic (i.e., B. bifidus and B. acetogenes), which are regarded as highly beneficent. The effect of this change, according to the author, is that the acid produced by the latter organisms inhibits the activity of, or actually destroys, any putrefactive organisms present. The evidence on which this statement is based was the fact that when the fæces were inoculated on a potato medium marked acid formation took place, while growth on broth containing boiled white of egg only rarely was followed by proteolysis indicating an action on the part of the putrefactive organisms.

It is very questionable how far it is legitimate to assume that the function of a flora in the body can be determined by an *in vitro* experiment of this rough order. To prove a change in flora of this character would require far more extensive bacteriological and biochemical research than has so far been devoted to the subject, and it is indeed remarkable that the author should make the astounding statement "that after this study the theory of chronic intoxication by the work of intestinal organisms cannot any longer be in doubt." As a matter of fact, it is not clear from the paper how often the fæces were examined in these cases, and whether samples were taken at operation from the bowel above the resection. If, as stated, only two examinations of the fæces at a year's interval were made, the data so obtained would be of little value. Such cases would require to be examined repeatedly before and after operation, and under all conditions of diet.

Distaso further asserts that the intestinal flora of the normal adult is noxious, and yet he asks the reader to rejoice with him over the microscopical appearance of the fæcal flora of one of these operated cases. This flora is characterised as "*une des plus belles,*" but certainly the flora of the constipated person seems far the more attractive, when drawings of each are placed alongside. With regard to the work done by the Metchnikoff school on the influence of food on the composition of the fæcal flora, I would merely refer to certain experiments of Bertrand, who found that rabbits fed on potatoes always gave a marked indican reaction in the urine, while those fed on carrots gave no such reaction. When a carrot rabbit was placed on potato diet indican appeared. The intestinal flora of the two groups did not differ qualitatively, but the potato rabbits had more B. coli in the fæces. No quantitative data on this point are supplied. Bertrand's view was that in the potato rabbit there was much less acid production from the fermentation of sugar than in the carrot rabbit, and consequently there was nothing to inhibit the formation of indol by the coliforms present. Also it is stated that the flora of the potato rabbit was very poor in amylolytic species, but data on this point are wanting.

It cannot be said that work of this kind advances the subject far. One is tempted to ask why chemical examinations of the intestinal contents were not made at various levels and accurate records given of the organisms met with at these levels. In all the recent work on autointoxication and on sour-milk therapy it has to be remembered that the inhibition of intestinal putrefaction by milk and milk constituents, especially milk sugar, was known years before Metchnikoff popularised the administration of milk soured by lactic acid bacilli.[2] As pointed out by Kendall, the effect of such treatment may be due not to acid produced by the bacilli supplied but to that produced by the B. coli acting on the sugar which is increased in the diet. Protein is thus spared, and consequently protein decompostion products do not appear. A bacteriological basis for the view that the activity of lactic acid bacilli inhibits that of the putrefactive organisms is still lacking.

In conclusion, I am of opinion that the investigation of the biochemical action of intestinal organisms yields a very large and promising field for future research and may throw a flood of light on this question of autointoxication, but it does not seem to me that the results achieved in the types of researches so far published by the Metchnikoff school lend any very marked support to the thesis.

Lister Institute, Chelsea.

---

[2] See an excellent survey of this subject by Kendall, 1912, Journal of Medical Research, vol. xxv., p. 117.

York County Hospital.—On the nomination of the President of the Royal College of Surgeons of England, Sir Cooper Perry, medical superintendent of Guy's Hospital, with a legal assessor, on April 18th opened an inquiry at the York County Hospital into the charges of mismanagement at this institution made in the *Hospital* by late resident medical officers. The inquiry concluded on the 19th.

VACCINATION FOR VARIOUS INFECTIONS WITH LIVING MICRO-ORGANISMS.

(BESREDKA'S METHOD.)

BY W. BROUGHTON-ALCOCK, B.A., M.B. CANTAB., M.R.C.S. ENG., L.R.C.P. LOND.

From the Laboratory of Professor Metchnikoff at the Pasteur Institute, Paris.

I HAVE already detailed in an article published in THE LANCET[1] my reasons for undertaking experiments with living micro-organisms, the safety and advantages of the method of Besredka employed, and the clinical and laboratory findings on the first cases treated from a prophylactic standpoint.

The application to man of vaccination by living sensitised bacilli typhosi which I established, and by which later workers and myself (for it is now in use as a prophylactic treatment in many countries) have continued to find most gratifying results, together with favourable observations made on animals with sensitised living staphylococci and streptococci, have encouraged me in the undertaking of a series of experiments in the attempt to find a more satisfactory means of vaccination against the common diseases than that with dead micro-organisms Professor Metchnikoff and Dr. Besredka, to whom I have the honour to be an assistant, have taken a generous interest in my work, and I am deeply grateful to them.

My efforts have been directed against infections by various strains of staphylococci and streptococci, and against those due to the gonococcus I wished also to include those due to the pneumococci, but my failure to find a serum that would sensitise the strains of pneumococci I had has forced me, owing to lack of time to prepare one, to postpone any observations on man. Dr. H. G. Adamson, whose large clinical experience demands the fullest recognition, seemed in his interesting Goulstonian lectures, 1912,[2] to attach particular importance to the development of detectable immunity reactions in vaccinated patients, and added that "unless a micro-organism can do this, how can it be of use as a vaccine?" I do not wish to enter upon immunity problems, nor upon the question often discussed of taking anaphylactic conditions seen in certain skin diseases a step further into immunity. May I assume that the resistance to or prolonged treatment by mechanical, chemical, or electrical means necessary in some infections of the skin, and the fact that relapse is not uncommon, add justification to the attempts of vaccine workers? Jenner vaccinated ideally for small-pox and Pasteur for hydrophobia, in turning to good use their clinical observations, and I feel encouraged to follow those great masters, awaiting the day when one may fully explain and demonstrate immunity reactions.

The purpose of this article is to describe the clinical observations and results from the vaccination of 150 patients as a curative method of treatment. As my extended experi[illegible] have been undertaken in the applica[illegible] to man, and may serve as [illegible] raindications to others, I have entered rather fully into the details of the doses of the various vaccines, and the reactions and results are conscientiously reported. Also I shall describe the lines of procedure I have found to be safe and very satisfactory.

At the time of beginning these experiments the difficulties were numerous, and I was far from unconscious of the precautions necessary. Dr. Besredka very kindly discussed with me the facts we had in hand, the use to make of them, and the lines of safe procedure to follow. The most encouraging of our facts particular to this research was that an animal would support more sensitised than non-sensitised specifically virulent staphylococci or streptococci, and that by non-lethal injections of the same we could rapidly produce immunity But for the gonococci we had no such encouraging knowledge. The problems that presented themselves, and the manner in which I have attempted to elucidate them, will be seen by following the lines of procedure adopted in the various cases which are record below.

As is well established, the colour of a colony of staphy cocci pyogenes, the chain of a colony of streptococci, or th cultural characteristics do not denote their particular vi lence; nor the appearance of an individual his resistance requirements for immunisation. Symbiosis, by associati of strains of the same or different groups of micro-organism has to be considered. I can report that no ill consequenc have followed my experiments. The only misfortune w when I tried a non-sensitised strain of staphylococc pyogenes in my skin in comparison with the same sensitis organism on that of a patient. He had no ill effects. I h an abscess and lymphangitis necessitating an absence of fi weeks from the laboratory. The few injections of speci immune serum, together with the immunised micro-organis produced rather painful reactions and indifferent results.

Before recording the cases in series I may point out th in conducting observations on out-patients I found sor attended irregularly. Detailed reports on these are omitte but any observations of value gained therefrom will be co sidered in the *résumés* that follow. Almost all the cas recorded were selected by Dr. Darier and his assistant, I Civatte, in their extensive clinique at St. Louis Hospit Paris. They were from amongst those which they judg would not be readily cured by the usual methods of tre ment [illegible] to them for their kindne and [illegible] inestimable advantage their [illegible] n making my observation My results published bear their valued testimony.

Gonococcal series.—In 26 cases of uncomplicated acu gonorrhœal urethral discharge treated I have but once se the discharge cease and failed to find any gonococ during three or four weeks. I do not attach any value to th result. I have tried in varied doses autogenous, no autogenous, and polyvalent living sensitised vaccines. La the same dead up to injections of 3 billions. To one patie not at the hospital, I gave 100,000,000 non-sensitised livi gonococci from a 24 hours' culture direct from a ureth discharge. There followed no good effect, no local n general reaction. I also tried the associated vaccination living sensitised staphylococci albi (E.) and streptococ [illegible] failed to ameliora [illegible] that by vaccinati [illegible] was treated suffer from any extension of the infection or complication.

The cases of discharge with complications I shall divi for simplicity of description into two categories: (*a*) orchit and epididymitis; (*b*) rheumatism, tendinitis, periarthrit arthritis with exudation. I have as before only given detail those cases that present the fullest interest both showing the varied doses and degrees of response. In a 25 cases were treated.

In section (*a*) the results were most satisfactory. Mo patients were free from pain after the first injection; a fe needed two The two remaining cases were not free fro pain until the third was given—all within a week. The larg dose seemed to give the quicker relief. It took about thre weeks to reduce the infiltration to the size of a pea, a nodu remaining in the globus minor. I had two cases of relaps both apparently due to prolonging the interval, for rap amelioration followed the next injection. I saw no relatio between rapidity of relief and the previous duration of th infection.

In section (*b*) the results in four cases were quite remar able. After the first injection and within 48 hours acute inflamed joints that one could barely touch, in one case o 15 days' duration were freely movable without pain. Th exudation disappeared in three days. Vertebral pain an painful non-suppurating ganglions were also rapidly relieve by the first injection. The cure persisted when patients wer seen one month later. The only instances in which ther was not complete relief within a week were those of subacut tendinitis without exudation. They necessitated at leas 1–3 weeks' injection treatment. I have never read of no seen such rapid and good results from antigonococcal no antimeningococcal serum or unsensitised vaccines Th rapid action is as interesting a problem as *the fact recentl* detailed by Mr. L. S Dudgeon in the Croonian Lectures 1912,[3] that the "exudate contains opsonins and complemen vaccine to no less than 20 other patients I was impressed by his marked reaction, and to test his hypersensitiveness to it I gave 200,000,000 of the same vaccine in ¾ c.c. saline in the lower arm, and 500,000,000 of a single strain sensitised gonococcal vaccine in the upper arm. 24th: The reaction locally was again marked, that in the lower arm being more inflamed looking than that in the upper arm, though in neither case was the reaction so extensive as previously. The temperature rose again to 38·7° C., and was still 38·5° C. He had headache and malaise as before. 26th: On the night of the 24th the patient had a profuse perspiration and complained this day of a pain in the chest. I feared pneumonia or lighting up of old tubercle, as has been said to follow vaccination. The examination of sputum by injection into a guinea-pig and the complement-fixation test of blood were negative for tubercle. March 10th: Both knees painful and swollen, the right particularly; general health restored. 1,500,000,000 in ½ c.c. of sensitised polyvalent gonococci (E 14), serum A, 14 hours together at 37° C. 12th: Slight local reaction; temperature rose to 37·7° C. on the 11th; condition unchanged. As patient again felt weak I decided to discontinue the treatment.

---

[1] THE LANCET, August 24th, 1912.

[2] THE LANCET, April 6th, 13th, and 20th, 1912.

[3] THE LANCET, June 15th, 22nd, and 29th, and July 6th, 1912.

I publish this as one of those rare patients who are extremely sensitive to vaccination. At the same time he showed no improvement.

CASE 5.—E; female with a chronic vaginal discharge for 18 months. For 10 days the left wrist had been swollen and extremely painful on the slightest movement; an enlarged and tender axillary gland. Jan. 29th, 1913: 750,000,000 in 1 c.c. of a polyvalent (10 strains) [illegible] ed one month almost dry and diluted [illegible] cal reaction. The condition of the [illegible] had disappeared and the joint was only painful on the fullest movements. Same diminution appeared on ganglion. 1,250,000,000 of same in 1½ c.c. 19th: Very slight local reaction; wrist was entirely free; there was a slight grating unnoticed by patient. March 10th: Seen again. Patient was entirely free from any joint disorder and had no discharge.

CASE 6.—F, male, aged 38. Urethral gonorrhœal discharge, always slight, dated from one month ago; arthritis of several joints for three weeks; orchitis and epididymitis for five days. Patient could not move his wrist nor shoulder and could just hobble. He had been in bed and treated for ten days without relief. Jan. 11th, 1913: 250,000,000, in 1 c.c. saline, of sensitised polyvalent gonococcal vaccine preserved almost dry, one month. 13th: Very slight local and general reaction; temperature rose to 37·8° C. The disappearance of the pain was most remarkable. The wrist could be freely moved. There was, however, no diminution in the volume of the testicular mass. Discharge unaltered. He walked quite well. 500,000,000 of same in 2 c.c. saline. 15th: Very slight local and no general reaction. Pain had entirely disappeared. Epididymis and testicle just distinguishable, the former still sensitive to pressure. Discharge very small. 500,000,000 of same in 2 c.c. 18th: Very little local reaction, none general. Mass was gradually diminishing in volume and the elements were distinct. Feb. 12th: Patient reported that the same testicle had suddenly and without obvious cause become swollen and tender. The condition appeared to be only transitory and passed away. The testicle was not enlarged or tender, but there were two painful nodules, one in each globus of the epididymis. Discharge only seen each morning. 250,000,000 of same in 1 c.c. saline. 17th: No reaction; patient said there was no morning discharge. 500,000,000 of same in 1 c.c. saline. 24th: No reaction; the epididymis was again painful. Patient had passed blood with nocturnal emission and at stool. Prostate examined; appeared normal. 2,000,000,000, in 1 c.c saline, of sensitised gonococci (10 strains) prepared from a living culture 10 days old; specific serum; sensitisation at 37° C. 26th: Slight local reaction and headache for 12-36 hours. Pain and blood-flow disappeared. 2,000,000,000 of same in 1 c.c. saline. March 1st: Slight local reaction for 12-36 hours. 2,000,000,000 of same in 1 c.c. saline. Slight local reaction only. A small infiltration nodule alone persisted in the globus minor.

CASE 7.—G, male, in-patient. Gonorrhœal urethral discharge for three weeks; for several days both knees and shoulder-joint were swollen and painful; orchitis and epididymitis on left side; temperature 38·6° C. at 11 A.M. Dec. 15th, 1912: 500,000 000, in 1 c.c. saline, of a sensitised polyvalent (10 strains) gonococcal vaccine. 16th: No local reaction; the temperature rose in the evening to 39·3° C. and fell to 37·5° C. this day. The pain had disappeared from the knees and shoulder, and the fluid could now just be detected. The testicle was free from pain, except to pressure, and was smaller. The epididymis and cord remained very firm, but were not so sensitive. The improvement was so definite as to be striking. 18th: 500,000,000 of same vaccine in 2 c.c. saline. 19th: No general or local reaction; testicle normal; epididymis and cord still firm, but not tender. Patient was about the ward. 23rd: 1,000,000,000 of same vaccine in 1½ c.c. 24th: Slight local and general reaction. Jan. 6th, 1913: The discharge was unaltered, but of the orchitis there only remained a small nodular mass of the size of a small pea in the tail of the epididymis, and slight thickening of the cord.

CASE 8.—H, male, aged 28, in-patient. He had twice had generalised gonorrhœal rheumatism with about two years' interval. Then he had a third attack, again following fresh infection or relapse; this had never been relieved despite constant treatment, including antimeningococcal serum during 50 days—doses 5-30 c.c. with 11 days' interval. The patient could not move the knees, thighs, vertebral column, or shoulders, and there was slight stiffness in most other joints. Only the knees contained an exudate and were painful, the shoulder joints were also painful. The patient had been rigid and confined to bed since this last attack, a period of five years. Feb. 26th, 1913: 1,000,000,000 in ½ c.c saline of sensitised gonococci (18 strains) prepared from a living ten days old culture; specific serum; sensitised in stove and cupboard. March 1st. Very slight local reaction. The night and day following injection the patient had headache and malaise. The temperature was as follows; 26th, evening, 37·6° C.; 27th, morning, 38·?° C; evening, 38·3° C.; 28th, morning, 37° C.; evening 37° C. The pain in the knees was markedly diminished; no fluid in right knee-joint; a little still remained in the left. 2,000,000,000 of same in 1 c.c saline. 3rd: No reaction; condition unchanged. 3,000,000,000 of same in 1 c.c saline. 5th: No reaction. 3,000,000,000 in 1 c.c. with ½ c.c. antigonococcal serum. 8th: Local reaction, area 6 cm., painful; after two days still infiltrated; knees not painful. 3,000,000,000 of sensitised gonococci in 1 c.c. saline (14 hours at 37° C., serum A). 10th: Very slight local reaction. Left knee free from fluid and much less pain, and that only on attempting movement. 6,000,000,000 of same in 2 c.c. saline. Slight local reaction only. A sudden change from the fine weather brought back the same condition to the knees. The patient remains under treatment.

CASE 9.—I, male, aged 21. Gonorrhœal urethral discharge; marked [illegible] is; chancre on the lower lip one month; [illegible] He was receiving mercurial injections. [illegible] in [illegible] (18 strains) prepared from a 10 da[illegible] sensitised in incubator and cupbo[illegible] very slight local reaction on the [illegible] receive 30 cg. of neosalvarsan on March 4th, I postponed vaccination. I remarked that in this case neither mercurial injections nor acute syphilis influenced the reaction, nor was the reaction to neosalvarsan marked.

CASE 10.—J, female, aged 19, out-patient. Gonorrhœal vaginal discharge for 2½ years; tendinitis of tendo Achillis with exudation for ten days; less swollen during last two days, but still very painful. March 1st, 1913: 2,000,000,000 in 1 c.c. of sensitised gonococci, polyvalent; Serum A; sensitised in incubator and cupboard. 3rd: Erythema and œdema over area of 10 cm. on arm; headache 24 hours; pain less; swelling hardly noticeable. 1,500,000,000 of same in 1½ c.c. saline. 6th: Reactions similar; pain still less; no swelling. 1,500,000,000 in ½ c.c. saline and ½ c.c. antigonococcal serum, the mixture not being centrifuged after sensitisation. 8th: Reaction similar, but extremely painful; feverishness, 38° C. It was noticed that there was always pain if the serum were not removed. The pain of the tendinitis and the exudation had entirely disappeared

CASE 11.—K, male, aged 23. Sycosis of the beard on the right side and of the moustache and right eyelids; duration 18 months. Culture: Staphylococci aurei and albi. Much previous treatment. Face never irritating. Dec. 7th, 1912: 30,000,000, in 1 c.c. saline (a vaccine made 16 days), staphylococci citrei. No local or general reaction, but patient complained of a marked itching of the face the night following the injection. 9th: 30,000,000, in 1/10 c.c. saline, of a sensitised vaccine, staphylococci aurei isolated from a patient with a suppurating ganglion following a whitlow of the finger. No reaction. This is in marked contrast to the fact that I gave exactly the same dose, first injection, to another patient, and a large abscess followed. Pus from the latter gave the staphylococci aurei pure. 12th: 60,000,000 in 1/5 c c. saline; no reaction. 19th: 150,000,000, in 1 c.c. saline, of his own isolated staphylococci aurei (sensitised, living). 21st: The external surface of the whole upper arm was red, hot, and œdematous; no temperature. 23rd: Less area was affected, but a localised abscess was forming. This abscess exuded much pus from day to day, leaving on Jan. 11th, 1913, a small area of 2 cm. of indurated subcutaneous tissue that pitted on hard pressure. He never had an elevation of temperature over 37·3° C. This strain has in all cases shown most marked virulence. The other vaccines had not vaccinated for this high initial dose. Until the formation of the abscess the improvement in the patient's condition was slow but manifest; and there was no spread of the disease. Since the abscess the condition was worse, and the other side of his moustache region was now affected. Jan. 11th: 50,000,000 of same vaccine (autogenous) in 1 c.c. saline. Slight local reaction, no general reaction; no temperature. 13th: Same dose, 50,000,000 in 1 c.c. saline. The face was remarkably better. There were no new pustules, and the inflammation had subsided. The patient had never had any itching of the face. The abscesses were most rapidly healing up. 15th: No reaction. The beard area continued in a satisfactory condition. Only the regions of the moustache and eyelashes were inflamed. 50,000,000 of same in 1 c.c. saline. 18th: No reaction. Condition most satisfactory; no pustules. 100,000,000 of same in 1 c.c. saline. 20th: Erythema 10 cm., œdema 6 cm.; no general reaction. The moustache and eyelid areas were but red, the former also scaly. There were no pustules. 23rd: All reaction had passed. 100,000,000 of same in 1 c.c. saline. 24th: No reaction. Eczematous condition of upper lip alone remained. 29th: 150,000,000 of same in 1 c.c saline. Feb. 4th: Small abscess formed at site of injection. Pus removed by a pipette gave [illegible] 12th: A pure staphylococcal cultures aerobica[illegible] small pocket of pus had not absorbed. [illegible] Condition unchanged; no new pustul[illegible] saline. 15th: Slight local reaction during two days. [illegible] of same in 1 c.c. saline. 17th: A red nodule appeared at point of inoculation with no serous œdema; no general reaction; satisfactory condition persisted. This may be contrasted with the fact that he was never free from pustules during 18 months of constant treatment, including electrolysis prior to vaccination. 200,000,000 of same in 1 c.c. saline. 19th: Slight transitory local reaction, none general. There were no pustules, and all that remained were two or three patches of hardened epidermal tissue where the eczematous condition had been most marked. 24th: Progress persisted. 250,000,000 of same in 5/8 c.c. saline. 26th: Local redness and infiltration of 3 c.m. in diameter persisted. Cure persisted. March 1st and 3rd: Cure persisted. On the 3rd injection of 500,000,000 of same in 1 c.c. saline. 6th: Slight erythema only. Local reaction of Feb. 26th passing. 10th: Reactions passed. Face still quite clear. It is interest ing to note to what a high resistance the patient had been prepared when commencing with a smaller dose.

CASE 12.—L. Furunculosis for several months; had not been ameliorated by dead unsensitised vaccines or ordinary treatments. Culture [illegible] pure staphylococci aurei. Sep[illegible] living staphylococci aurei. [illegible] perature; no new pustules. 2[illegible] No local or general reaction [illegible] same. Oct. 5th: 5,000,000 in 1¼ c.c. saline 0·8 per cent. [illegible] 1 square inch on the following day; no subjective symptoms; no temperature. Improvement in pustules slight. Oct. 8th: 12,500,000 in 1 c.c. saline. Slight local tenderness; redness 1 square inch; no general symptoms. The local tenderness lasted during three days. Oct. 12th: 25,000,000 in 2 c.c. saline. Very slight local and no general reaction. Nov. 21st: 16,000,000 in 1¼ c.c. saline. Very slight local reaction; no general reaction. 23rd: 32,000,000 in 2½ c.c. saline. The local reaction was noticeable; there were œdema and erythema about 2 inches in diameter which disappeared on the fourth day; highest temperature 37·5° C. 27th: 32,000,000 in 2⅔ c.c. saline. Slight œdema and erythema locally the day following, which disappeared after two days; highest temperature 37·6° C. Dec. 2nd: 56,000,000 in 1⅔ c.c. saline. No local or general reaction. 4th: 56,000,000 in 1½ c.c. saline. No local or general reaction 7th: 100,000,000; very slight local and no general reaction

now non pustular inflamed areas had appeared. It was striking to see this benign form. The patient did not cease work during the treatment.

CASE 13.—M, male, aged 40, out-patient. Furunculosis of neck, duration some months. On the ba

comedones. Culture gave staphylococci aurei and albi. Feb 15th, 1913: 25,000,000, in 1 c.c. saline, of
cultured from acne pustule in pr
reaction. 50,000,000 of same in
reaction; condition unchanged.
26th: No reaction. No new pust

1 c.c. saline. 3rd: Slight local reaction lasting 12–48 hours. Only one small pustule had appeared; the old ones were but red and disappearing. 250,000,000 of same in 1 c.c. saline. 12th. No reaction.

vaccination.

CASE 18.—R, woman, aged 30. Four large *plaques of seborrhœic*

covered by scabs. Cultures gave staphylococci aurei and albi; the colonies of each about equal. Dec 21st, 1912: 5,000,000 of sensitised living staphylococ

DONATIONS AND BEQUESTS.—Mr. Samuel Newton, J.P., has endowed a cot at Ashton District Infirmary at a cost of £1000.—Mr. Murdoch McLeod, of Lytham, left the residue of his property—£4500 net—to be divided equally between the Manchester Royal Infirmary and the Christie Hospital, Cancer Pavilion and Home.—At a recent meeting of the Governors of Nottingham Hospital it was reported that when Mr R. M Knowles, a former high sheriff of the county, was asked to give some evergreens for ward decorations at Christmas he sent instead a cheque for £1000, suggesting that that might be of more permanent use.

THE TESTS FOR ACETOACETIC ACID, INCLUDING A SIMPLE NEW TEST.

BY WILLIAM HOLDSWORTH HURTLEY, D.SC. LOND.,
LECTURER ON CHEMISTRY, ST. BARTHOLOMEW'S HOSPITAL.

THE tests at present in use for detecting acetoacetic acid, excluding those which depend upon its conversion into acetone, are as follows :—

1. *Addition of a solution of ferric chloride.*—This test was discovered by Gerhardt[1] in 1865. He found that the reagent only gave the characteristic colour with the urine of some and not with that of all diabetic patients, and with the urine of notorious drinkers. For a long time he was unable to ascertain what the substance was which caused the colour formation; he then observed that the colour was identical in appearance with that given by a substance which Geuther had obtained in 1863 from ethyl acetate by acting upon it with sodium and acidifying the product. Geuther called his new compound diacetic acid ether, and also dimethylene-carbonic-acid ethylene ether, and later (1865) he called it ethyl diacetic acid. He showed that it could easily be decomposed into acetone, carbon dioxide, and alcohol. This compound is now called ethyl acetoacetate, and Gerhardt believed that it was this substance which caused the colour when ferric chloride was added to certain urines; he also expressed the opinion that acetone, which had been found in diabetic urine ten years before his discovery, is a decomposition product of diacetic acid ether.

Deichmüller,[2] at the instigation of Ebstein and Tollens, and Tollens[3] showed in 1881 that ethyl acetoacetate does not occur in diabetic urine, for if it did such a urine should yield by suitable treatment very nearly four parts of alcohol for every five parts of acetone. They distilled two litres each day of a urine which gave a strong iron reaction until they had worked up 40 litres. From this distillate they prepared pure acetone, but they could obtain no test at all for alcohol. Tollens also showed that if ethyl acetoacetate is added to a urine and the urine is then distilled some of the substance always distils unchanged, and the distillate smells of it and gives a colour with ferric chloride; a diabetic urine never does this. They therefore concluded that the colour-producing substance was acetoacetic acid or its salts, not its ester.

The name diacetic acid, which was originally applied by Gerhardt, following Geuther, to ethyl acetoacetate, is still often used as a name for acetoacetic acid; its use might very well be discontinued. The delicacy of the ferric chloride test when tried on a solution of sodium acetoacetate is very nearly 1 in 100,000; it is less than this in urine on account of the presence of other substances which give a red colour with the iron salt. It has also the disadvantage that numerous drugs give with ferric chloride a violet colour very similar in tint to that given by acetoacetic acid.

2. *Arnold's test.*[4] [5]—This valuable test does not appear to be as well known as it deserves to be. Two solutions (*a*) and (*b*) are made as follows. (*a*) 1 grm. of para-aminoacetophenone is dissolved in a little water with the aid of 2 c.c. of concentrated hydrochloric acid, and the solution is made up to 100 c.c. (*b*) 1 grm. of sodium nitrite is made up to 100 c.c. Two volumes of (*a*) and 1 volume of (*b*) are mixed, and an equal volume of urine is added to the mixture, then a drop or two of strong ammonia. A reddish-brown precipitate is produced. To a portion only of this a large excess of concentrated hydrochloric acid is added (15 c.c. to 2 c.c.). If acetoacetic acid is present a fine purple colour is produced. Arnold strongly recommends filtering the urine through animal charcoal before applying the test. He states that in this way the delicacy of the test is increased and also more urine can be added to the mixture of (*a*) and (*b*) than can be added if unfiltered urine is used.

Lipliawsky[6] states that the sensitiveness of the test is increased if, after adding the hydrochloric acid in excess, 3 c.c. of chloroform and 2 to 4 drops of ferric chloride are added, and this mixture cautiously shaken in such a way as to avoid an emulsion; the purple colour is taken up by the chloroform, forming a very stable solution. The explanation of the colour is that the aminoacetophenone is diazotised, forming the compound $CH_3CO.C_6H_4.N:N.Cl$, which couples up with the acetoacetic acid and produces the colouring matter, $CH_3CO.C_6H_4N:N\,CH\begin{smallmatrix}\diagup CO.CH_3\\ \diagdown COOH\end{smallmatrix}$. This formula is given to it by Riegler,[7] who obtained it in a crystalline condition.

The test is very delicate—1 in 40,000 according to Lipliawsky.[6] Ethyl acetoacetate gives the test as well as acetoacetic acid and its salts, but as far as is known it is not given by any other substances. It can be applied, therefore, to the urine of patients who have been taking salicylic preparations, antipyrin, and the like.

Arnold[5] claims to have shown by this test that acetone only occurs in urine in the severest cases of so-called acetonuria, such as grave cases of diabetes. Thus in a case where Legal's acetone test is positive, while Gerhardt's test is negative, Arnold's test for acetoacetic acid is positive; and if the urine in such a case be just alkalised with sodium carbonate and shaken with ether the ethereal extract will show neither Legal's nor Arnold's test, whereas if acetone were present it should show Legal's test but not Arnold's. If the urine is now acidified with sulphuric acid and extracted with ether the extract will show both tests.

3. *Absorption of iodine.*—This test is due to Riegler.[8] 15 c.c. of urine are shaken with 2 c.c. of a 10 per cent. solution of iodic acid and 2 to 3 c.c. of chloroform. In the presence of acetoacetic acid the chloroform remains colourless; in its absence the chloroform is coloured violet by liberated iodine. The explanation of the test is that there are substances present in urine which reduce iodic acid to hydriodic acid, which is then oxidised by unchanged iodic acid to water and iodine, the latter colouring the chloroform unless acetoacetic acid is present, in which case iodoacetoacetic acid—a colourless substance—is produced :

$$CH_3COCH_2COOH + I_2 = CH_3COCHICOOH + HI.$$

The chief substance in urine which reduces iodic acid is uric acid; but some urines contain so little uric acid in the amount taken for the test that no iodine is liberated. To overcome this difficulty Riegler[7] modifies his test thus: To 1 to 2 c.c. of a normal urine 2 c.c. of 10 per cent. iodic acid and 3 c.c. of chloroform are added; on shaking the chloroform is coloured violet; now 10 c.c. of the urine to be tested are added and the whole well shaken. If acetoacetic acid is present the colour of the chloroform disappears.

Lindemann[9] pointed out that the conditions necessary for success in applying Riegler's test are that the solution to be tested must be acid and that iodine must be present. He therefore modified the test in this way: 10 c.c. of the urine are acidified with 5 drops of 30 per cent. acetic acid, 5 drops of Lugol's iodine solution (1 grm. iodine, 2 grm. potassium iodide, and 100 c.c. water) are added, and this mixture is shaken with 2 or 3 c.c. of chloroform. No colour appears if acetoacetic acid is present in the urine.

In this form the test is approved by Riegler,[7] who points out that an idea of the amount of acetoacetic acid present can be formed from the amount of the iodine solution required to be added to produce a violet colour in the chloroform. The test is described as being more delicate than Gerhardt's, but less delicate than Arnold's. No other substance, which is likely to occur in appreciable amount in a urine, than acetoacetic acid gives the test.

Quite recently this test has undergone a further modification by Ondrejovich[10]: 5 c.c. of the urine are acidified with 5 drops of 50 per cent. acetic acid, and 1 drop of a 1 in 2000 solution of methylene blue is added; the liquid should be distinctly blue. On adding 4 drops of tincture of iodine the liquid turns red, but if acetoacetic acid is present in the urine the red colour turns blue or green at a speed which depends on the amount of the acetoacetic acid present.

Ondrejovich points out that if the urine is made too acid the restored colour of the methylene blue is green instead of blue; also that there are substances in urine besides acetoacetic acid, such as indican, which combine with iodine, but they are present in minute amounts and act far more slowly than acetoacetic acid. It is clear that this test is quantitative in the same sense as Lindemann's modification described above. No other substance than acetoacetic acid shows the test. Ondrejovich claims that it exceeds all the previous tests in delicacy. In this form the test is certainly a valuable and a sensitive one. In using the test I find that Lugol's iodine solution acts quite as well as tincture of iodine; also that when the amount of acetoacetic acid is very small the iodine—even Lugol's, which is less than half the strength of ordinary tincture of iodine—must be added very cautiously Thus, 5 c c of a 0 01 per cent solution of pure acetoacetic acid would only require two drops of Lugol's iodine solution

4 *Rothera's modification of Legal's test* —This test—which consists in adding 5 grm of ammonium sulphate to 10 c c of the urine, then 3 drops of a 5 per cent solution of sodium nitroprusside (freshly made), and 2 c c of strong ammonia, when a fine permanganate colour is obtained—is described by Rothera [11] as characteristic for acetone The limit of delicacy of the test is given by Rothera as 1 part of acetone in 20,000, at which dilution the colour requires half an hour to develop I find, however, that the test is far more delicate for acetoacetic acid than it is for acetone, the permanganate colour is developed with acetoacetic acid in the form of its sodium salt at a dilution of 1 part of the acid in 100 000 very distinctly in two minutes, and faintly at a dilution of 1 in 400,000 in five minutes Rothera states that both ethyl acetoacetate and acetoacetic acid fail to give the permanganate colour with his test Owing to the kindness of Dr F G Hopkins I am able to give what appears to be the correct explanation of this discrepancy Dr Hopkins informed me that Rothera s test for acetone is inhibited by the presence in the acetone of ethyl acetoacetate Acting upon this information, it was found that quite small quantities of the ester completely inhibited the test when applied to the acid

That the test is really a test for acetoacetic acid as well as for acetone is shown by the following experiments 13 grm of chemically pure ethyl acetoacetate were treated with 100 c c of normal caustic soda solution, and the mixture was made up to 500 c c In 16 5 hours at the room temperature (20° C) 25 c c of this solution required 0 45 c c one fifth normal sulphuric acid for neutralisation, in 44 5 hours it required 0 1 c c of this same acid for neutralisation —that is the ester was practically all saponified From this a solution was made containing an amount of sodium acetoacetate equivalent to 1 grm of acetoacetic acid in 1000 c c A solution of chemically pure acetone was made containing 1 grm of acetone in 1000 c c

(*a*) By means of a pump a rapid current of air was drawn through 100 c c of the acetone solution After three hours suction the liquid failed to give Rothera's test for acetone By means of the same pump air was drawn for three hours through 100 c c of the acetoacetate solution, it gave the test as strongly after the suction as before it

(*b*) 100 c c of each of the above solutions were heated side by side in a boiling water bath in flasks provided with efficient reflux condensers for one hour At the end of this time the acetone solution gave the test unimpaired in strength, but the acetoacetate solution having been hydrolysed to acetone now gave a feebler test than the acetone solution, for 0 1 grm of acetoacetic acid only gives 0 057 grm of acetone on complete hydrolysis

Legal [12] says of his own test that it is a test for acetoacetic acid, as well as for acetone, but not a test for ethyl acetoacetate It would appear, therefore, that Arnold's statement that acetone is of rare occurrence in urine is probably correct, the usual clinical tests applied for the purpose of detecting the supposed acetone are really tests for acetoacetic acid

5 *A new test* —This is performed as follows To 10 c c of the urine add 2 5 c c of concentrated hydrochloric acid and 1 c c of a 1 per cent. solution of sodium nitrite, shake and allow to stand two minutes Now add 15 c c of strong ammonia, followed by 5 c c of a 10 per cent solution of ferrous sulphate or a solution of ferrous chloride of equivalent strength (2 grm of iron in 100 c c) Shake up, pour into a 50 c.c Nessler glass, and allow to stand undisturbed. It is not advisable to filter A beautiful violet or purple colour is produced The reaction is a *slow one*, and the speed at which the colour develops depends on the concentration of the acetoacetic acid in the urine the colour deepens for several hours after its first appearance

The explanation which I offer of the test is that the acetoacetic acid is converted by the nitrous acid into isonitrosoacetone, which forms a salt with the ammonia, the ferrous salt then produces a purple coloured salt from the ammonia salt by double decomposition

$$\underset{\text{Acetoacetic acid}}{CH_3CO\,CH_2COOH} \rightarrow \underset{\text{Isonitrosoacetone}}{CH_3CO\,CH:NOH} \rightarrow \underset{\text{Ferrous salt}}{(CH_3CO\,CHNO)_2Fe}$$

That isonitrosoacetone in alkaline solution forms coloured salts on the addition of ferrous sulphate was first shown by Dr Martha A Whiteley [13] The test has been tried on several normal and on a large number of pathological urines, and on the urine of patients taking salicylic preparations; but only urines which react with the other tests for acetoacetic acid give this test Acetone does not give the test, but an aqueous solution of ethyl acetoacetate gives a pure blue colour—not a purple—and it only gives the blue colour when much more nitrite is used than is prescribed in the test above As regards delicacy, the test, when performed on a solution of sodium acetoacetate, prepared in the way already described, shows at a dilution of 1 part of acetoacetic acid in 50,000 parts of solution

Of all the tests described it seems the most suitable for obtaining an idea of the amount of acetoacetic acid present in a urine For this purpose a solution containing the equivalent of 1 0 grm acetoacetic acid per 1000 c c is prepared (*ante*) From this, by dilution solutions containing the equivalent of 0 025 0 02, 0 15, 0 01 grm of acetoacetic acid in 100 c c are prepared * The test is now performed according to the prescription given on 10 c c of each of these four and on 10 c c of the urine If the colour develops much more quickly in the urine than in the 0 025 solution, the urine must be diluted 10 or 20 times, and the test repeated on the diluted urine In four or five hours the colours will be well developed and the initially turbid liquids will have become quite clear, the urine can be placed in its position among the standards, and so the percentage of acetoacetic acid is determined with fair accuracy In order to test the accuracy of this method the "total acetone" in the urine of a diabetic patient was determined by the paranitrophenylhydrazine method of Moller [14] The results are given in the table and the amount of β hydroxybutyric acid is included

Date	Per cent acetoacetic acid by colour method	Per cent "total acetone" calculated as acetoacetic acid by Möller's method	Per cent β hydroxy butyric acid	Total urine, c.c
Feb 24th 1913	0 25	0 31	0 83	3880
,, 25th ,,	0 40	0 30	1 09	3960
,, 27th ,,	0 31	0 30	0 82	3420
,, 28th ,,	0 30	0·32	0 82	3670
March 1st ,,	0 30	0 33	0·92	3220
,, 2nd ,,	0 30	0 28	0 97	3000
,, 3rd ,,	0 30	0 38	0 83	3160
,, 4th ,,	0 30	0 33	0 92	3760
5th ,,	0 24	0 24	0 62	1655
,, 6th ,,	0 24	0 19	0 46	2900

It will be seen that the colour method gives quite a satisfactory idea of the amount of acetoacetic acid present in a urine, also that even in a severe case of diabetes there is not much acetone present as such in a fresh urine The highest percentage of acetoacetic acid I have observed so far in four different cases and about 60 specimens of urine is the 0 4 per cent recorded above when 43 grm of β hydroxybutyric acid were excreted in the 24 hours

This question of acetoaceturia (rather than acetonuria) is still engaging my attention I propose to examine some of the methods for the separate determination of acetone and acetoacetic acid I am greatly indebted to Dr A E Garrod, F R S, for allowing me to have specimens from his ward, the four cases examined were all in his wards I am also much indebted to Mr F Cahen, my assistant for much help in the experimental work of the paper

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

◆

NOTE ON A CASE OF PRIMARY HYDATID OF BONE.

BY C. E. RUSSEL RENDLE, F.R.C.S. EDIN.,
LATE ASSISTANT SURGEON, SOUTH DEVON AND EAST CORNWALL HOSPITAL.

THE patient, a woman aged 67 years, came as an out-patient to the South Devon and East Cornwall Hospital complaining of the inconvenience caused by a large tumour over the sacral region, which prevented her sitting or lying back with any comfort. She had a small lipoma in the right hypochondrium which had been there for over thirty years, and stated that the lump behind had been gradually enlarging for nearly four years. It measured about 10 in. by 6 in., was situated over the right sacrum and sacro-iliac joint, extending a little beyond the middle line; it was dull to percussion, of doughy consistency, no thrill, no definite fluctuation. I admitted her with a view of removing the tumour, which I took to be a lipoma or thyroid dermoid.

The tumour was more or less definitely encapsuled, but while freeing the base, which was firmly attached over the end of the ilium, I cut across a tube with a glistening membrane which turned out to be the lining of a hydatid cyst. A probe passed some 4 or 5 inches through a very small opening into apparently a bony cavity. I enlarged the opening and scraped out a considerable quantity of membrane and daughter cysts and drained the cavity. There seemed no connexion with the abdomen. The patient went on very well for some time, the wound gradually closing up, but she was the subject of chronic bronchitis, which troubled her a good deal, and suddenly her heart began to fail, and she died in two days.

At the post-mortem examination no hydatid could be found in any other organ of the body; the brain was not examined, but there was no reason to suspect anything wrong there. The ilium was found to be hollowed out into a large irregular cavity, with the remains of some membrane, and I can only conclude that it was the situation of the primary cyst, which had expanded and thinned the posterior margin, and finally burst through and overflowed into the subcutaneous tissues of the back. The patient had never been abroad, but had lived all her life in the neighbourhood.

NOTE ON THREE CASES OF SPLENIC ABSCESS OCCURRING IN SO-CALLED "MALARIAL CACHEXIA."

BY F. E. WILSON, M.B., CH.B. EDIN,
CAPTAIN, I.M.S., AGENCY SURGEON, MESHED, PERSIA.

DURING the past few years I have been struck with the frequency of splenic abscess occurring in cases of so-called "malarial cachexia," and by the disappearance of the "cachexia" on treatment directed against the local condition. So common is it in my experience that I now make it a practice to look carefully for evidences of splenic suppuration in all cases of malaria with splenic enlargement which are resistant to ordinary treatment.

on which I rely in making a diagnosis in such ontinuance of fever under thorough quinine r the disappearance of all forms of the ripheral blood; (2) local evidences of rence to the abdominal parietes; and probably occurs in the spleen is the trophied splenic tissue, this being e blood stream. Unfortunately y facilities at my disposal to sm in each instance. Below I ses.

Tochi Valley; a small poorly developed man in advanced cachexia. The spleen was adherent to the abdominal wall, which was ideally thin for palpation. About 1½ pints of viscid, yellow pus were removed, and a soft drain was left in the wound. The man went out very much improved.

CASE 2.—Male, aged 35, Peshawar; in advanced cachexia. The adhesions were less firm in this case, and the surface of the spleen was first stitched to the abdominal wall before opening the abscess. About a quart of pus escaped, followed by a sharp hæmorrhage, but this was controlled by hot saline adrenalin solution. In spite of careful nursing the patient died from exhaustion three weeks later.

CASE 3.—Male, aged 30, Meshed; cachexia not marked. Recent scars from some native actual cautery over the splenic area. A pointing abscess in the abdominal wall leading into the large adherent spleen was opened, the lower margin of the spleen being very hard. About 1¼ pints of thick pus escaped, being followed by slight hæmorrhage. Microscopically this pus contained leucocytes, myelocytes, a variety of organisms, but no malarial parasites. The patient went out greatly improved.

I have ventured to record these cases in the hope that the short notes may be of use to those who are working in tropical or subtropical climates, by directing attention to a common but little described cause of the persistence of apparent malarial cachexia.

NOTE ON A CASE OF ACUTE PULMONARY ŒDEMA IN AN INSANE PATIENT.

BY J. F. CORSON, M.D. VICT., D.P.H. CAMB.,
LATE ASSISTANT MEDICAL OFFICER TO THE BUCKS COUNTY ASYLUM.

THE following case of death from acute pulmonary œdema is of some interest on account of the existence of a peculiar delusion of persecution which may have been associated with a previous pulmonary attack. My acknowledgments are due to Dr. H. Kerr, the medical superintendent of the Bucks County Asylum, for permission to publish the case.

The patient, a female, 30 years of age on admission, was admitted to the Bucks County Asylum on July 16th, 1895. She was pregnant and gave birth to a child four days after admission. Her mental state at that time was one of depression, with anxiety and fears of persons entering her room. She was thin and rather anæmic, and her heart sounds were described as weak and muffled, but it is stated that there was no cardiac murmur. Her health improved and she became fat, and except for some slight degree of anæmia appears to have shown no symptoms of physical disease until her death. Her mind did not recover, and she became chronically maniacal, with frequently recurring exacerbations and remissions. About six months before her death she complained that another patient had put soap into her mouth whilst she was asleep in bed, and that it had nearly choked her. This was not regarded at the time as having any special significance. Her general health continued good, and she worked steadily at the ordinary housework of an asylum ward.

On April 1st, 1911, the patient was found dead in bed at 10.15 P.M. by the night nurse. When I saw her she was lying on her back, her nose and lips were covered with white froth, and her lips were livid. According to the accounts of fairly reliable patients in the same dormitory, she got out of bed shortly before 10 o'clock, and was seized with a severe attack of coughing. She returned to bed and the coughing continued for some minutes, and she complained of pain in the chest. She was quiet afterwards, and was thought to be better again.

At the post-mortem examination the heart was found to be hypertrophied, and weighed 12 oz. There was marked stenosis of the mitral orifice; the mitral valve was thickened and there were small vegetations on the cusps. The aortic valve cusps also showed small vegetations. Both lungs were distended and filled with frothy exudation.

The case appears to have been one of acute pulmonary œdema, and the delusion that soap had on one occasion been put into her mouth during sleep may have arisen from a previous attack.

Medical Societies.

ROYAL SOCIETY OF MEDICINE

SPECIAL MEETING OF FELLOWS

Continued Discussion on Alimentary Toxæmia [1]

A MEETING of the Fellows of the society was held on April 21st Sir FRANCIS H CHAMPNEYS the President, being in the chair

Mr P LOCKHART MUMMERY in reopening the discussion said that little was known as to the true pathology of alimentary toxæmia He disagreed with Mr Lane as regards the so called adhesions found in cases of alimentary toxæmia and pointed out that in many instances they were not real adhesions but abnormal folds of peritoneum He attributed the cause of this condition to the neglect of constipation in early life He insisted upon the importance of a careful

said he believed that many of the crippling cases of chronic arthritis owed their origin to alimentary toxæmia and that the disease might be arrested in its early stage by proper treatment directed to cure the condition of the colon As regards the choice of operation Mr Mummery was in favour of appendicostomy when possible and thought the more serious operation of eserved for those cases in to give relief He attache careful after treatment in these cases and pointed out that acetonuria more frequently occurs after operation in cases of alimentary toxæmia than after operations in which this condition is not present

Professor ARTHUR KEITH said that he came forward that evening as a representative of that humble and somewhat neglected group of men whose business it was to impart a sound knowledge of the structure of the human body to medical students and medical practitioners It seemed to him that the present generation of anatomists had appeared at an unfortunate time when medical men in general and surgeons in particular, had lost faith in human and comparative anatomy as a source of help in enabling them to solve the practical problems of applied medicine He wanted therefore to place before the Fellows the anatomist s point of view—so far as it bore on the present discussion During the last 20 years our teaching and our research had been greatly influenced by the various movements which had cumulated in the present discussion In reality this discussion centred round the nature and function of the great intestine He would deal first with the formation of peritoneal adhesions—a matter which had received and which was receiving a great deal of attention from anatomists Anatomists were at once brought face to face with one of the most striking of all the developmental changes seen during the growth of the fœtus There could be no doubt that man came of a stock in which the mesentery and bowel were originally arranged in a primitive and simple manner for in the second month of development the human intestine and its mesentery had the lineal arrangement seen in the lowest mammals Then during the third fourth and fifth months of fœtal life a profuse adhesive process set in—a regulated embryological peritonitis—which led to the cohesion of mesenteries and viscera to the posterior wall of the abdomen—an adaption as they supposed to the upright posture for it was only in those upright forms that we found these adhesive changes take place After the fifth month the process of adhesion proceeded more slowly and was completed about the time a child learnt to walk. The extent of the process was extremely variable How variable it was one could readily see by consulting recent papers by Dr Douglas Reid the monograph by Dr Henry M W Gray and Dr W. Anderson, or the fine treatise on the appendix by Kelly and Hurdon In about one newly born child out of every ten the process of adhesion would be found to have bound the mesentery of the lower part of the ileum to the pelvic fossa giving the condition which was associated with ileal kinking The extent to which adhesions were produced between the cæcum and ascending colon varied but a condition which gave rise to a "Jacksonian membrane was not rare, wide adhesions at the region of the hepatic and splenic flexures were always present—all these adhesions were parts of a normal embryological and useful process They recognised however, that all peritoneal adhesions in the ileo cæcal region were not embryological and normal, one saw occasionally in adult bodies a degree of adhesion never seen in the child at birth and anatomists recognised that some of the adhesions were the result of pathological processes The majority of the adhesions, often regarded as pathological in nature were in reality mere expressions of a normal and healthy fœtal process The question of ptosis or dropping of the viscera was also one which had interested anatomists They had recognised the frequency of this condition before they were aware that Glénard had scheduled visceroptosis as a distinct pathological entity and long before they succeeded in convincing their colleagues, the clinicians of the frequency and the importance of the condition It was a fortunate circumstance that at that time the discovery of Roentgen placed a new means of inquiry in the hands of anatomists A study of the living diaphragm convinced them that the essential feature of the abdominal viscera was not their fixity but their mobility, they were so attached that they could move freely with the respiratory tide It became apparent to all of them that mesenteries and visceral ligaments only came into action when the limits of normal movement were reached, the musculature of the abdominal wall was the essential mechanism for supporting the viscera The pathology of visceroptosis was therefore to be sought in a better understanding of the nerve relationships which existed between the viscera and their supporting walls The researches of Sherrington Hill MacKenzie Elliott and many others showed them how closely the tone and contraction of the abdominal parietes were related to the posture of the body and to the condition of the viscera They had not yet solved the problem of how the tone and contraction of the musculature of the body wall and of the alimentary canal were coordinated but they had sufficient evidence to lead them to suspect they were regulated by a common nerve mechanism It was probable that this mechanism might be acted on and deranged by pathological products generated in the intestine and that visceroptosis was one of the manifestations of alimentary toxæmia He now came to the essential question round which the present discussion had revolved What is the functional value of the human great intestine? At the beginning of the present century a sharp divergence of opinion set in In the years 1902 and 1903 three men—an anatomist Barclay Smith a bacteriologist Metchnikoff, and a surgeon Arbuthnot Lane—came independently and by a different train of reasoning to the same conclusion—so far as man was concerned the great intestine was not only a useless but a pernicious structure That was a very significant fact, in Paris London and Berlin the condition of the great intestine was then forcing itself on the attention of thoughtful medical men To anatomists who knew that the great intestine was an intrinsic part of every air breathing vertebrate that it reached a high degree of development and specialisation in every mammal that included a vegetable element in its diet that in all the animals immediately allied to man—his contemporaries and his very ancient predecessors—the great intestine was shaped arranged and developed as in him —the conclusion that the human great bowel was a useless structure seemed a flat contradiction of every law applicable to the animal body It was hard to believe that a great structure which had served that long chain of ancestors carrying man s lineage through the secondary and tertiary periods of the earth s formation and assisting man to become the dominant and universal species of the world, should suddenly fail him They seemed driven to the conclusion that it was not the organisation of the great intestine that had failed, but that our modern dietary set a task for which it was not adapted In civilized modern communities the great bowel had to manipulate a dietary such as was never before prescribed to it at any stage of its long evolutionary history If an engine ran unsatisfactorily it might not be from a fault in its mechanism but from a defect in the fuel Those who regarded the great bowel as a useless structure blamed the engine; for his part he stood by those who blamed the fuel. Let them look at the evidence on which the useless and pernicious nature of the great bowel was based. The great bowel could be excised and health maintained; that proved it was not an essential structure. If diseased, excision might lead to improved health; that proved no colon was better than a diseased one. What must be proved, however, before they regarded the colon as a useless structure was that a man without a colon was in a better state than the man with a healthy colon. It would be time enough to relegate the great bowel to the list of useless structures when that much was proved. This problem of the great bowel was really a child of our ignorance; we had only a vague knowledge of its rôle in the economy of the animal body. If we kept before us the history of progress in medicine it was not likely that anyone would presume, because he did not know the use of the colon, that it had no function and was a useless structure. Every year saw some structural part, formerly placed with the useless or vestigeal structures, removed from that list. Only a few years ago Pavlov and Starling introduced us to the elaborate mechanism which controlled the exit of the contents of the stomach to the duodenum; it was certainly their investigations which led him to look for a similar mechanism at the junction of the ileum and colon. Elliott demonstrated that such a mechanism existed at the time he was carrying out research on the movements of the great intestine. He (Professor Keith) felt certain that Dr. Hertz was right when he attributed the effects, which Mr. Arbuthnot Lane ascribed as the result of a kinking at the terminal part of the ileum, to a derangement of the ileo-cæcal sphincteric mechanism. Every step forwards in our knowledge cut the ground from under those who took a purely mechanical view of the action of the great intestine. Evidence he had accumulated lately justified him in supposing that the mechanism for regulating the passage of food from the ileum to the cæcum of man was more elaborate than we supposed. Besides the muscular fibres which were situated directly at the ileo-cæcal orifice, and which evidently were designed to secure that orifice against reflux from the cæcum, there was also a mechanism for regulating, as Dr. Hertz suggested, the passage of the contents of the ileum to the cæcum. The musculature of the terminal part of the ileum for an extent of nearly 4 inches (roughly 10 cm.) above the ileo-cæcum junction was endowed with a special tonic function; it served as a sphincter for the terminal part of the ileum. He would also like to take that opportunity of emphasising the need of having every diseased colon removed by operation systematically and minutely investigated. His friend Professor J. W. Smith, of Manchester, had recently given him an opportunity of examining a very complete specimen removed by operation. There was mucous colitis throughout the whole of that part of the great intestine which was excised with abundance of intestinal sand scattered along the lumen. A typical ileum kink was present 4 inches above the ileo-cæcal orifice. The musculature of that part of the ileum was strongly contracted. The terminal 4 inches of ileum was bound down to the pelvic fossa by a peritoneal adhesion exactly similar to that seen in a proportion of normal newly born children. There was nothing in the nature of the iliac adhesion to suggest that it differed in origin and nature from the natural band seen so often in children.

---

[1] THE LANCET March 15th (p 754) and April 19th (p 1093) 1913.

Mr. GEORGE ROWELL said that his remarks would be confined to the condition which Mr. Lane had named "chronic intestinal stasis." Among the many subjects included in this discussion on alimentary toxæmia it would seem to be of prime importance to examine and ascertain how far facts supported Mr. Lane's revolutionary proposition. The regard in which the theory was held was changing rapidly, and at the present time the position was of much interest, for every degree of agreement with Mr. Lane was now to be found in the profession. Speaking generally, it would appear that many of those who had given the most attention to the conditions which were actually to be found inside the abdomen were the most in accord with Mr. Lane's views. It was because he had seen a large proportion of Mr. Lane's work on cases of chronic intestinal stasis from its beginning that he ventured to take part in the debate. No one who had seen Dr. C. Mayo's photographs of the ileal kink could doubt the existence of the characteristic band. He had seen this demonstrated to the onlookers at operations scores of times in the most unmistakable manner. He had also seen the fastened-up appendix, crossing and obstructing the end of the ileum, similarly demonstrated on numerous occasions. Whether the new structures causing these two forms of abnormality were inflammatory or not in origin did not matter with reference to the results produced. In both cases it was easy to demonstrate that there was a fixed point, and it was obvious on examination that the sagging of the bowel in the vertical position of the trunk must in each case cause some obstruction. One frequently saw long coils of intestine drawn up out of the pelvis in these operations, of which the only fixed attachment was the point alluded to. What the amount of obstruction actually was would also seem to be not necessarily a matter of moment, the important point being that cases exhibiting these structures displayed in a definite manner the symptoms described by Mr. Lane as those of chronic intestinal stasis. Again, the exact nature of the particular poison in any case was also a minor point so far as diagnosis and treatment were concerned, the weighty consideration here being that when the obstruction was relieved by operation the symptoms disappeared. He had seen the bands which had developed in connexion with the duodenum and the sigmoid demonstrated many times in the clearest possible manner, and he had frequently seen the duodenum dilated, sometimes very dilated, in these cases. In many it had actually presented through the abdominal wound. In operations undertaken for duodenal ulcer he had several times seen ileal obstruction examined for and found. The adhesions described at the splenic and hepatic flexures and those supporting the stomach were also quite familiar to onlookers at Mr. Lane's operations. Most of the operations for the relief of chronic intestinal stasis at which he had been present during the last few years had been previously examined by the X rays and reported upon by Dr. A. C. Jordan. It was nearly always the case that the report had predicted accurately the condition that had been found. Indeed, one of the most striking things that he knew in surgery was the precision with which, when assisted by the X rays, the exact causation and degree of stasis could be diagnosed before operation. In his experience the X rays sometimes showed less than was found at operation; a kink was occasionally missed. Certainly he had never seen a dilated duodenum diagnosed by the use of the X rays that could not be demonstrated at the operation. As showing the importance of the ileal band was a group of cases of which he had seen many examples—patients in whom pain had persisted after the appendix had been removed. In these cases he had seen the ileal band divided and immediate relief result, although one understood that the relief might not be permanent without a short-circuiting. The general effects of chronic intestinal stasis were stated to include the impairment of every tissue. It was not easy to see the connexion; if it were, no doubt this would have been discovered long ago. Take, for example, thyroid enlargement. If it were true that the connexion existed it followed that the relief of stasis ought to diminish the size of the thyroid. Besides the interesting case given in Mr. Lane's introduction, he had on two occasions seen an enlarged thyroid diminish very rapidly after short-circuiting. In Dr. Hale White's opening paper he adduced a case of exophthalmic goitre which disappeared during an attack of typhoid. The rest in bed, the milk diet, and the diarrhœa during the illness obviously must have kept the patient without stasis for some weeks, so that instead of providing an argument against the theory that exophthalmic goitre was associated with chronic intestinal stasis, this case would seem to be in perfect accord with that belief. The cure of duodenal ulcer by rest in bed had a similar significance. With regard to cancer he had often seen the symptoms of long-standing chronic intestinal stasis demonstrated in cases of cancer of the breast, and repeatedly in cases of cancer of the bowel, disease of the gall-bladder and of the pancreas the ileal kink had been clearly shown. Pyorrhœa was a condition held by Mr. Lane to be a result of chronic intestinal stasis, though he (Mr. Rowell) did not suppose that he would deny the possibility of a direct infection, as, for example, from pet dogs. As he saw cases of pyorrhœa almost daily, he would like to remark that he had seen complete cures by vaccines as well as by scrupulous local treatment, and that he knew of many cases in which the cure had been much aided by paraffin internally. Two of his dental friends of large experience in this disease made an almost routine practice of prescribing paraffin for these cases, and one of them had told him that he did not know whether the paraffin or the local treatment had the largest share in effecting a rapid cure. Certainly his experience was that it was quite unnecessary to remove all the affected teeth in pyorrhœa. A large number of facts were being brought to light in various branches of medical knowledge which, when examined, were found to fit in with, and to lend support to, Mr. Lane's theories. The question of infant feeding might be alluded to as an example. In 1901 Dr. Eric Pritchard came to the conclusion that disease in infants, and much in after life, was largely due to over-feeding during the first year. This, he held, caused over-development in the length of the bowel, such overgrowth often extending to many feet, for which there was no adequate room, and therefore peristalsis was impeded, and delay in the passage of the contents of the intestine resulted. For the prevention and treatment of this condition he had given paraffin very largely, and, agreeing with Mr. Lane, was convinced that the constant exhibition of paraffin had a marked effect in both the prevention and the cure of tuberculosis. The fact had been alluded to that he had repeatedly seen the disappearanc [illegible] ore or less rapidly according [illegible] after the operation of [illegible] ithout colectomy. In many of the worst cases the results after some years were even more remarkable. With reference to the points of interest in connexion with anæsthesia in sufferers from chronic intestinal stasis he had already given the results of his experience, and as this matter was of small general interest he would only call attention to the fact that by the use of the method that had been described the risk of the anæsthetic was practically a negligible quantity, and shock and after-sickness were commonly absent. He had never seen acetonuria, probably because he never used chloroform in these cases. To conclude, he would submit, for what it was worth, with great respect to those whose work lay in the diagnosis and treatment of disease, that the facts one had been able to observe, so far as they had gone, completely supported Mr. Lane's views.

Dr. W. Langdon Brown regarded alimentary toxæmia as due to either (1) abnormal intestinal flora or (2) normal intestinal flora acquiring an abnormal habitat. *Pari passu* with the introduction of the normal bacteria into the intestinal tract after birth the body acquired means of defence against them. An infant in whom normal bacteria were planted too early might be unable to resist them, and he instanced cases of septicæmia due to B. coli and B. aerogenes capsulatus thus induced. A similar diminution in resistance was seen in old people in whom B. coli septicæmia might occur without local lesions. Proteins putrefied and carbohydrates fermented; and to a certain extent these processes were antagonistic. It was the aromatic groups and the sulphur groups in the protein molecule which were specially prone to putrefaction. The ordinary products of putrefaction were rendered inert by conjugation with glycuronic acid or sulphates. Garrod had prognosticated the approach of carboluria by finding the proportion of ethereal sulphates in the urine rising, which was a more reliable sign of impending toxæmia from putrefactive bodies than the presence of indican, which also had the disadvantage of being unstable and disappearing from the urine on standing. The comparative failure of the phenol compounds as intestinal antiseptics was probably due to their depriving the body of the power of rendering putrefactive bodies harmless by combining with the sulphates. On the other hand, the value of sulphates in the treatment of certain intestinal conditions was not limited to their aperient action, as in this way they had an antitoxic action also. To illustrate the point that abnormal intestinal bacteria were responsible for toxæmia in many cases he dealt with microbic cyanosis, paroxysmal hæmatoporphyrinuria, and the formation of pressor diamines. In each of these there was evidence of the action of some special organism, and he thought that renewed study of these conditions, where the chemical changes were relatively simple, would probably throw light on the vaguer states often referred without positive evidence to alimentary toxæmia. The reaction of the body against these simple poisons was quite different to that adopted against foreign proteins and bacterial toxins. No antibodies were developed, but simple processes of oxidation, dehydration, and combination with glycuronic acid, bile salts, sulphates, and possibly glycogen occurred. The fact that the poisons in so many of these cases were not antigens considerably limited the application of vaccine therapy in alimentary toxæmia. He called attention to oral sepsis as a factor in producing atonic dilatation of the stomach, and adduced evidence against the recent view that the amount of acid in the gastric juice determined whether or no oral sepsis would set up rheumatoid arthritis.

Mr. Edred M. Corner said that the history of the progress of the infection of the alimentary canal with micro-organisms was very important, and must be thoroughly understood by those who desired to appreciate the practical bearings of the subject of alimentary toxæmia. Briefly, the life-history of an hypothetical individual with regard to alimentary toxæmia might be set forth as follows. As with the great majority of others, whilst the fœtus was in utero the contents of the alimentary canal were sterile and the physiological processes of digestion were inactive, so there was no chemical change taking place within the alimentary canal, toxins could not be produced, and any alimentary toxæmia was impossible. But with birth, or soon after, organisms were introduced into the alimentary canal and a life-long intestinal education was begun. Being unused to the products of the action of micro-organisms the baby's tissues suffered. This was seen in the very frequent gastro-intestinal irritation of the newborn, breast-fed or artificially fed; also, perhaps, in the secretion of fluid by the peritoneum in the abdomen, seen when a patent processus vaginalis was present as a hydrocele. Should the baby's resistances overcome its alimentary toxæmia all would be well. But should the actions of the toxins prevail the child would get rickets, a result of the action of what might be called alimentary toxins on the growing tissues. Of course, alimentary toxins, or toxins absorbed from the alimentary tract, were not the only ones that could produce such deleterious action on growing tissues. Others might be absorbed from the tonsillar region. Still our profession regarded the alimentary toxins as the most important by far in the production of rickets. Rickets was not the only result of severe alimentary toxæmia in childhood. Many other diseases might be mentioned, such as wasting, thrombosis, osteoarthritis, and so forth. Indeed, by lowering the resistance of the tissues of the child alimentary toxæmia might be said to render the entrance of organisms to the body more easy. Thus it would dispose to tuberculosis of the mesenteric glands, and to an infinite number of diseases. From this life-long intestinal education we learnt to endure alimentary toxæmia until a certain amount of alimentary toxæmia was physiological to us and necessary to our well-being; our powers of resistance to such toxins increased and increased until with mature years and equanimity we could overcome such a feast as the "City banquet." As life progressed the tissues of the alimentary tract were affected directly and the rest of the body indirectly. The results of the organisms in the alimentary tract were known, and formed different chapters, so to speak, in our book of intestinal sepsis. Appendicitis was at once the most frequent and dangerous result of intestinal sepsis. Colitis and its ulcerative form were others. Later in life there were gastric and duodenal ulcers. All the affections mentioned hitherto affected primarily the mucous membrane of the bowel. But the sepsis affected more than the mucous membrane. The action of the muscular coats might be interfered with, producing delay in the passage of the intestinal contents—constipation, or, as it had been called, "intestinal stasis." But in addition to the inner and middle coats of the bowel the peritoneal covering membrane might be irritated—in the young leading to the formation of a hydrocele, and in the older to the formation of adhesions. The results and treatment of the adhesions, and the kinks caused by them, had already been gone into by Mr. Arbuthnot Lane. It must suffice that of his (Mr. Corner's) own experience he could tell them that some patients were vastly improved by such operations as short-circuiting or colectomy, with and without appendicostomy, others were neither better nor worse, whilst a small number were even made worse by any attempt at operation. In the excitement and heat of so large a discussion as this, points of practical issue were apt to be overlooked or buried in accumulation of theories and scientific observations. That some patients were vastly improved by operation was, he knew, beyond doubt, and he thought that improvement could not have been attained by any other means. Therefore he would strongly urge that for our future progress data be suggested by means of which we could differentiate those who would be improved by operation from those who would nor be benefited. This was very important from both the patient's and the surgeon's point of view. Surgeons owed many of their failures and inabilities to improve patients suffering from alimentary toxæmia because so much time had been lost before it was decided to resort to operative treatment. This brought him to a further point which he would strongly insist upon. Alimentary toxæmia was a progressive disease, or, perhaps better, the results of alimentary toxæmia were progressive; so that if the consideration of operative treatment was delayed, more and older changes (adhesions, mesenteries, &c.) would be encountered, and the surgeon would have still less chance of being able to benefit the patient. His inability to do so was not his, the surgeon's fault. It was the unfortunate result of delay; perhaps unavoidable, perhaps avoidable. And it must never be forgotten that the intestinal tract was only one of many systems of excretion whose faults might give rise to auto-intoxication. In conclusion, he would insist that the terms alimentary stasis and alimentary toxæmia were not synonymous. People might enjoy well-being, and perhaps health, while suffering from intestinal stasis, *if the intestinal contents dried and the micro-organisms consequently died.* But where the intestinal contents were *moist and organisms were abundant*, fermentation must occur, and alimentary toxæmia became sufficiently marked to require treatment. A course of waters and purgatives might accomplish the result required, provided no kinks or other variety of intestinal obstruction was present. Thus when alimentary toxæmia was recognised clinically, he would suggest that treatment by means of diet and purgation should be begun. While it was in progress an X ray examination should be made of the progress of the intestinal contents along the alimentary tract. If any obstruction existed, the surgeon must obviate it. But his work "merely made the paths straight" and afterwards treatment by diet and medicines must be continued.

Mr. **PETER DANIEL** said that he would like to state quite clearly at the onset what his views on intestinal toxæmia were and then to discuss the reasons why he held those views. They were: 1. That gastro-intestinal toxæmia was one of the commonest everyday causes of symptoms of diseases, if not the commonest. 2. That it was due to infection of the gastro-intestinal mucosa. 3. That in adult life such infection originated almost invariably from some suppurating septic focus in the mouth and nasopharynx or the nose and its accessory sinuses. 4. That it might be extremely slight in degree and manifestation, or intense and fatal. 5. That it was the common source of disease of the liver and gall-bladder and the pancreas; that gastric and duodenal ulcers and many other ulcerative processes were terminal phases of the infection. That appendicitis was but part of the infective process progressed to such a degree as to be of sufficient moment to merit special treatment. 6. That peritoneal infection leading to adhesions, thickenings, bands, and all their consequences, was the inevitable result of chronic infection of the mucosa. 7. That as a result of the infection the function of the mucosa and the chemical processes of digestion were perverted and interfered with. Also, that the musculature of the organs was always detrimentally affected, leading to weakness of action, so that finally the organs did not properly empty themselves nor did they propel their contents at a normal rate. 8. That visceroptosis was an exceedingly common outcome of such prolonged infection, from influences already indicated, and thus a vicious circle was set up. 9. That the sphincters did not function normally when the mucosa lining them was inflamed; the exact reaction generally depending upon the degree of inflammation. 10. That evolutionary bands were always secondary to visceroptosis and, like the latter, were due to chronic infection of the mucosa. 11. That ileal stasis was not due to bands and such mechanical agencies in the main, although such might aggravate the stasis in a limited number of cases, but that the stasis was always an evidence of the presence of chronic infection of the bowel and was due to it. The stasis disappeared when the infection was cured, although the bands might remain. That many cases of stasis were apparent and not real—i.e., the ileum contained a bismuth meal unduly long because the stomach (the reservoir which supplied the ileum with its bismuth meal) was unable to empty itself at the normal rate. Thus there was a constant dribble of bismuth meal coming along into the ileum, and as long as this dribble persisted so long would the ileum show a shadow. 12. That in considering ileal stasis insufficient attention was devoted to the altered physiological processes as a cause of delay. 13. He did not believe that "food toxins" played a great part in the symptomatology of intestinal toxæmia, because if one cured the septic lesion of the mucosa without in any way altering the food of the patient one cured invariably the symptoms of toxæmia. They had also been told on good authority that the food toxins were not poisonous when taken by a healthy person by the mouth, and experimental research had shown that they were not absorbed when manufactured *in situ* in the bowel as long as the intestinal mucosa was undamaged. Under all counts, therefore, before food toxins could take part in producing toxæmia the mucosa must be damaged already. It was the bacteria swallowed from the septic focus in the upper digestive tract which damaged the mucosa. 14. What he believed to be the most potent toxin in the process of intestinal toxæmia was the toxin evolved by the bacteria themselves, especially the cocci which were found in such numbers in these septic cases in the mucus adhering to the mucosa and in the epithelial layers of the membrane. In the examples given by previous speakers of food poisons he would indicate that the underlying reason why the particular patients suffered poisoning was because they were in a septic state. The literature teemed with instances of Henoch's purpura being associated with sepsis in the gastro-intestinal tract. Scurvy in particular he had no hesitation in ascribing to oral and gastro-intestinal sepsis. Stasis was quite unnecessary for toxæmic absorption; a bladder acutely inflamed ejected urine much more frequently than normal, yet the patient had fever and other symptoms of toxic absorption.

Mr. **C. H. FAGGE** intervened in support of the view for so many years advanced by Mr. Arbuthnot Lane, that in many cases of intestinal toxæmia mechanical factors, in the shape of adhesions, bands, a false mesentery, produce kinks with intestinal stasis as their result, and that the operative treatment of these kinks is of the first importance.

Mr. **H. W. CARSON** wished to limit his remarks to that form of intestinal toxæmia which resulted from intestinal stasis, and referred briefly to two conditions—viz., parenchymatous goitre and the mastitis of young unmarried women, the cure of which, he thought, depended upon the cure of intestinal toxæmia. He considered that intestinal toxæmia resulted from excessive bacterial action and diminished elimination of toxins in the intestine, and that this was dependent on stasis of the intestinal contents. He believed that constipation was the original cause, and that as a result the cæcum, weighted down by retained fæcal matter, tended, in the erect position, to prolapse, and stasis also occurred in the ileum as a result of backward pressure. To overcome the tendency to prolapse bands formed in certain definite positions—between the parietal peritoneum and the ascending colon, the first part of the sigmoid and the terminal part of the ileum. These bands were not inflammatory, but were at first protective in their action, though later they interfered with peristalsis and even caused definite organic obstruction. From the point of view of treatment the important factor was the preliminary stasis in the cæcum and ascending colon. Medicinal treatment should be tried at first, but if ptosis was marked, and especially if adhesions were present, it would probably be ineffectual. He considered that the presence of adhesions could be demonstrated by an X ray examination after a bismuth meal and by the character of the pain. Operation was justifiable if thorough medical treatment had failed to give any, or only temporary, relief, and also in cases of adhesions. The choice of operation lay between dividing adhesions and short-circuiting the large intestine by implanting the proximal end of the divided ileum into the pelvic colon. If the first course was adopted the cæcum should be anchored by sutures into the right iliac fossa. Operation must be followed by six months' medical treatment.

Mr. KENNETH W. GOADBY said that much stress had been laid upon "swallowing pus," as if this fluid in itself was the actual cause of intestinal disturbance. It appeared more reasonable to regard the local absorption and infection through the actual site of inflammation as the chief means of invasion. Particularly must this obtain in *pyorrhœa alveolaris*, where the primary effect was lowering of general bod[illegible] sion of the mucosa of [illegible] the curious comple[illegible] ith the condition. He [illegible] ive and unselected cases of suppuration of the alveolar process of the jaws. Thirty-six—i.e., 24 per cent.—had no general *symptoms*, notwithstanding the swallowing of pus for at least two years; 64, or 42 per cent., had definite symptoms of gastro-intestinal affections. Localised points of infection, not generalised suppuration, were associated with the largest number of cases with intestinal symptoms. Again, 56 per cent. of all the cases had rheumatic symptoms. In none of the cases was gastritis an acute symptom, and no history of gastric or duodenal ulceration was obtained in any case. Anæmia of secondary or toxic type was a feature in 66 cases. Affections of the portals of the alimentary canal produced secondary changes in the whole organism, not so much by the passage of their products into the stomach as by the entrance of bacteria and their toxins into the blood stream in the affected areas, while conversely processes of the lower parts of the alimentary canal or blood might affect the oral tissues. In the treatment of pyorrhœa alveolaris both local and general measures were essential. General and local resistance should be increased by means of autogenous vaccines, and followed by surgical treatment upon ordinary lines. He entirely dissented from the proposition that the only remedy for pyorrhœa was extraction.

Mr. E. C. HUGHES drew attention to the peritoneal bands which are frequently met with in the abdominal cavity, without any sign of inflammation of the contained viscera. He considered them to be developed to prevent the downward displacement of the intestines. Lane's ileal kink and band showed three chief characteristics: (1) it was 3 to 4 inches away from the termination of the ileum; (2) the band was attached to the antimesenteric border rotating it; and (3) the band was on the under surface only of the mesentery. Could an inflammation of the appendix produce the same result in 100 per cent. of cases? The ileal kink was certainly evolutionary in origin. In the [illegible] frequently affected by these bands, one or other of them getting attached to it at some part of its length, so that its mobility was impaired. But the more common position of the appendix was for it to be attached to the under surface of the mesentery of the small intestine, either entirely or almost entirely with the terminal inch free. In this condition the appendix was acting as a suspending ligament of the cæcum. These adhesions were responsible for nearly all cases of acute and chronic appendicitis. The adhesions impaired the mobility of the appendix, so that it was unable to discharge its secretions efficiently; the secretions accumulated and formed the fæcal concretion. Conditions were favourable to the development of bacteria in the stagnating contents. An acute inflammation of the appendix, beginning in the interior, might arise at any moment, the virulence of the affection depending on the quality and quantity of the bacteria and the resistance of the individual. The appendix, which was partially adherent and had its termination free, was liable to kinking or torsion at the junction of the fixed and movable parts; a complete and lasting kinking would be followed by gangrene of the movable part; a temporary kinking *on being relieved would be followed by intense* congestion and finally recovery. The symptoms and results of the former type would be far more severe than those of the latter, where no opportunity would have been afforded for the growth of bacteria. It was on account of the impossibility of knowing which type of appendix was at fault that the appendix must be removed at once in an attack of acute appendicitis. Chronic appendicitis was due to the same causes, [illegible] r less marked. Removal [illegible] In appendicular dyspe[illegible] over the right iliac fossa there were the symptoms of duodenal ulceration, removal of the appendix frequently cured the condition. But there was a large number of cases where the removal was followed by no benefit. It was probable that those cases were cured, in the absence of an ileal kink, where the appendix was acting as the suspensory *ligament of the cæcum, and as it did so through its attachment* to the mesentery it obstructed the ileum, behind which it was passing, and caused a delay in the discharge of the ileal contents into the cæcum. Anyone who had seen much of Mr. Lane's operative work must be convinced that his explanation of intestinal stasis was correct, but it was not yet clear what were the indications for operative treatment.

The debate will be resumed on Monday, April 28th, at 5 P.M.

SECTION OF LARYNGOLOGY.

Exhibition of Specimens and Cases.

A MEETING of this section was held on April 4th, Mr. HERBERT TILLEY, the President, being in the chair.

The PRESIDENT announced that a proposition to admit as members of the section clinical assistants who had served for one year at recognised clinics had been approved by the council, and would be presented at the general meeting.

The PRESIDENT showed: 1. A Shawl-pin which he had removed from one of the hyparterial branches of the bronchus of a woman aged 42. The pin point was directed towards the observer, and appeared only as a thread of mucus. Twice it slipped from the forceps, but was eventually drawn out with the bronchoscope. Morphia, atropine, and chloroform narcosis were employed, while the trachea and larynx were painted with 20 per cent. cocaine. 2. A T-shaped instrument with which the outer part of the tonsil is compressed and septic material expressed; the tonsil is rotated thereby so that the crypts are readily examined.

Mr. G. N. BIGGS showed: 1. An almost complete Cast of the Epithelial Lining of the Œsophagus, which was vomited three days after the patient had swallowed one ounce of chloroform. Rectal feeding was employed, and bismuth, lanoline and paroleine given every four hours by the mouth. Œsophagoscopy three months later gave no indication of contraction. 2. Specimen *from a case of lympho-sarcoma* in a child, aged 13, admitted with three weeks' history of enlarged glands in the neck and a swollen tonsil of dark maroon colour. The growth spread with appalling rapidity and became gangrenous. The child died from toxæmia 16 days after admission. The glands of the neck and mediastinum were extensively involved.

Mr. E. A. PETERS exhibited a case of *Cyst of the Aryteno-epiglottidean Fold* which burst spontaneously with a rent in the upper surface. He stated that some of these cysts disappeared rapidly on puncture, while others required removal of a considerable part of the wall. In this case the cyst appeared to be reforming.—The PRESIDENT had experienced redistension with some cysts and had found it necessary to remove a considerable part of the wall; he considered that a multilocular character explained the history in some cases.—Dr. H. W. FITZGERALD P[illegible] of the cyst by the cautery [illegible] lining.—Dr. WILLIAM HI[illegible] and alluded to the removal of a cystic mass from this region.—Mr. E. B. WAGGETT would use suspension laryngoscopy and remove part of the cyst wall.—Mr. G. W. BADGEROW had noticed the frequent disappearance of these cysts on mere puncture.

Dr. J. DONELAN showed a case with a Cyst on the Epiglottis with symptoms suggestive of œsophageal stricture. The cyst was small and associated with a scarred condition resembling healed syphilis or lupus.—Dr. FITZGERALD POWELL contended that the symptoms must be due *to a growth and not to the small cyst.*

Dr. DONELAN again brought up his case of Post-diphtheritic Adhesion of the Palate, as there was no evidence of syphilis in the case.—The PRESIDENT considered the possibility of diphtheria alone as the cause of the preceding ulceration as slight.—Mr. PETERS suggested the common association of diphthe[illegible] of the condition.—I[illegible] recall a case of such [illegible] his experience.

Mr. E. D. D. DAVIS exhibited a healthy-looking man with Tuberculous Disease of the Epiglottis and tubercle bacilli in the sputum.' It was found impossible to remove the whole of the disease with punch forceps but with Killian's suspension laryngoscopy apparatus the epiglottis was readily trimmed with forceps and scissors.—The PRESIDENT alluded to the advantage of the suspension apparatus in such manipulations, as both hands were freed by the laryngoscopy apparatus.

Mr. W. G. HOWARTH brought the Tumour removed from the patient on view at the last meeting. The extensive dissection had been effected with the aid of Kuhn's per-oral intubation apparatus, which had obviated a tracheotomy. The extraordinary history revealed the sequence of a papilloma in January, a fibroma in March, and finally a round-celled sarcoma in September, all affecting the soft palate.—Dr. DAN MCKENZIE considered the case unique.

Mr. F. F. MUECKE exhibited a patient on whom tracheotomy was performed six years ago for Tertiary Obstruction of the Larynx, and who was still carrying a tracheotomy tube. There appeared to be a mass of granulations, though the patient could breathe through the larynx.

Mr. G. SECCOMBE HETT presented a man who was able to speak after removal of one cord, and the anterior part of the other cord, two and a half years ago for malignant disease. The result had been contributed to by exercises instituted by Mr. C. MacMahon.—The PRESIDENT considered the result an excellent one.

Dr. WILLIAM HILL's case of cicatricial contraction of the lower part of the pharynx and paresis of the cords due to myopathic changes was discussed. Killian's dilation apparatus was employed. A small rubber tube was retained *in situ* and enabled the patient to swallow liquid food.

A discussion followed on the question of nasal feeding. Dr. HILL was in favour of feeding per os. It was suggested that the nasal route was unsatisfactory when the nasal passages were either irritable or diminished by vasomotor rhinitis or other obstructions.

SECTION OF OTOLOGY.

Functional and Simulated Affections of the Auditory Apparatus.

A MEETING of this section was held on April 18th, Dr. J. DUNDAS GRANT, the President, being in the chair.

Mr. T. MARK HOVELL introduced a discussion on Functional and Simulated Affections of the Auditory Apparatus. [illegible] thought a general consideration of [illegible] as knowledge of it, especially in re[illegible] less clearly defined than that of most oth[illegible] thement, seemed [illegible] tions. The term "functional deafn[illegible] life[illegible] aural manifestations [illegible] misnomer, because deafness meant [illegible]ss" was somewhat of a that of hearing. Many of the case[illegible] the loss of a function— arose in persons who wished for exem[illegible] simulated deafness service, and others among those who hoped to obtain pecuniary advantage from simulating disability due to accident or other cause. But there were also cases of apparent suppression of hearing power as the result of a violent emotional influence, and others in which deafness was simulated without any apparent object, or in which deafness was due to a temporary lack of nerve power. Among these latter must be included those who practised masturbation. In dealing with a case of suspected simulation care must be taken to avoid being prejudiced by statements emanating from people associated with the patient. Where there appeared to be no motive for loss of hearing the patient should be removed from uncongenial surroundings, and the examination should be directed to the discovery of any existing disease. In many cases of simulated deafness the onset was sudden, the voice modulations were not altered, and there was an absence of that quick movement of the eyes seen in most deaf persons, showing a desire to obtain the knowledge which they were precluded from receiving through the ordinary channel. Tests which could harm the patient should always be avoided, such as firing a pistol close to the ear. Where there was no apparent reason for the simulation, recovery was sometimes hastened by the medical attendant behaving as though he considered the case genuine. Sometimes, when making an examination and conversing with the friends in an ordinary tone, a casual request in the same tone to the patient to put out his tongue would throw him off his guard, and he would respond. Mr. Hovell concluded by describing in detail a number of tests employed.

The PRESIDENT demonstrated a case of the condition in an unmarried woman, aged 29, who suffered from cardiac trouble and was in somewhat feeble health, and who had had a syncopal seizure. For the detection of malingerers, especially those alleged to be suffering from caisson disease, he had found the use of the tuning-fork on the vertex very helpful. Some forms of function deafness seemed to be due to self-hypnosis, and such cases were sometimes considered to have been cured by some fanciful form of treatment.

Dr. W. MILLIGAN (Manchester) regarded the medico-legal aspect of these cases as very important, and many of the instances he had found it very difficult to unravel. One of the best tests he knew was that of the vestibular reactions, for these and the vertiginous symptoms were in hysteria "all up and down"; tests on separate occasions did not give the same responses.

Dr. H. MACNAUGHTON-JONES objected to the term "hysterical deafness," and said he regarded hysteria as a distinct entity, with characteristic nerve symptoms; it was apart from either neurasthenia or psychasthenia. Neurasthenia meant nerve fatigue, and in that fatigue the auditory apparatus participated. He did not think he had ever come across a case of true hysterical deafness.

Dr. DAN MCKENZIE alluded to the functional disability in old cases of organic deafness, under which the nerve centres, not being exposed to the usual stimuli, fell asleep, and this factor intensified the degree of the deafness.

The discussion was continued by Mr. HUGH E. JONES, Mr. E. B. WAGGETT, Mr. P. M. YEARSLEY, Dr. L. H. PEGLER, and Mr. G. J. JENKINS. Mr. HOVELL replied.

MEDICAL SOCIETY OF LONDON.

Exhibition of Clinical Cases and Pathological Specimens.

A MEETING of this society was held on April 14th, Sir W. WATSON CHEYNE, the President, being in the chair.

Dr. F. PARKES WEBER showed a specimen of Primary Tumour of Bone (Endothelioma?). It was obtained from a woman, aged 54 years, who was admitted into hospital on May 29th, 1912. In September, 1911, she had complained of pain in the shoulder and down her back, worse when [illegible]. In January, 1912, she took to her bed and was treated for neuritis, and remained in bed until her admission to hospital. When in bed her chief pain was in the neck, shoulders, and back. The pain in the neck seemed to cause stiffness of the jaw. Latterly she had had excruciating pain and stiffness in both legs, but the arms had never been affected. She had had a slight cough. On admission the patient was very thin, but she had a bright [illegible] There was marked kyphosis of the lower cervical and upper dorsal regions of the spinal column, from the sixth cervical to the sixth dorsal vertebræ. There was pain on pressure over the kyphotic area, but not lower down. The muscular power was feeble; she could scarcely raise her legs from the bed. The knee-jerks were absent. On Oct. 9th, while the patient was being lifted on to the bed-pan, a fracture of the left femur in the region of the trochanter occurred. In November the urine was tested repeatedly for albumose (Bence-Jones protein), but none was found. All through the illness the temperature varied between 97° and 99° F. Death took place on Nov. 23rd, 1912. At the necropsy the liver was found to be crinkled and nodular; its cut surface showed numerous small yellow nodules. The bones were very friable; the ribs could be broken like rotten twigs, and the laminæ of the vertebræ could be easily cut through with scissors. Two specimens were sent to Dr. Weber. One was half of the neck and great trochanter of the left femur, the cancellous tissue and bone marrow of which were practically altogether replaced by new growth; the other was part of the right lobe of the liver, which was diffusely infiltrated with a pale-looking new growth. No swelling of lymphatic glands was observed at the necropsy, nor were tumours noted in any of the soft parts other than the liver. In the microscopical examination of the specimens Dr. Weber was indebted to Dr. J. C. G. Ledingham for great assistance. The liver was found to be infiltrated with miliary nodules of new growth, which histologically resembled the new growth in the bone, the latter being apparently primary. The tumour substance consisted of medium-sized cells arranged in alveolar groups, with a *generally rather scanty fibrous framework* The tendency to alveolar grouping was especially noticeable in the tumour from the bone The nuclei of the tumour cells varied much in different parts of the growth Some of them were round or oval in shape, large in proportion *to the amount of cytoplasm, and more or less* vesicular in appearance Others were much smaller and irregular in shape, often eccentric in position, and staining deeply with hæmatoxylin The cytoplasm showed no particular granules No giant cells were seen Some of the cells in their general appearance and staining resembled the clear cells with small deeply stained nuclei which constitute the most characteristic histological feature *of the Gauch* [illegible] *ibed and* illustrated by I [illegible] "System of Medicine" [illegible] 766-69) In the growth in the bone a few mitotic figures were observed —Mr. E H SHAW said that in his opinion the growth was one of primary carcinoma of the liver and secondary metastasis in the bones

Dr WEBER also showed a case of Large Asymmetrical Cervical Ribs in an old man without arm symptoms The patient was aged 80 years When examining him some years ago (about 1908) Dr Weber felt a hard lump on the left side of the neck just above the left shoulder The patient was unaware of its existence, and the question arose, *Was it a tumour of recent development, or had it been there* a long time and escaped the patient's notice? A Roentgen ray examination was made in 1908 in Germany, and the following report was given "The tumour above the left shoulder is not a bony lump, nor a cervical rib, it might be a neuroma, as pressing or moving it causes a pain all along the nervus brachialis" There could scarcely be a doubt that this X ray examination was one with the fluorescent screen only and without skiagraphy On March 18th last, at Dr Weber's request, Dr N S Finzi took skiagrams of the patient's neck, and demonstrated the presence of large cervical ribs on both sides, but the right one dipped downwards more steeply than the left *This steep inclination downwards of the right one* was the reason why only the left could be palpated as a distinct hard lump at the root of the neck As the patient was fat and had a thick neck it was not surprising that an X ray examination without skiagraphy should fail to reveal the real nature of the condition Dr Finzi pointed out that the cervical ribs were jointed, the one on the left seeming to articulate with the first rib, whilst the one on the right probably articulated with the second rib The case also illustrated the well known fact that large cervical ribs often gave rise to no particular symptoms which directed attention to their presence

Dr J L BUNCH showed two cases of Hereditary Dupuytren's Contracture The patients, father and son, were members of a family the male members of which were said to have been affected with Dupuytren's contracture for the past 300 years In every case the disease was said to commence about the same age, to attain its maximum about the same age, and to affect precisely the same fingers of both hands The first symptom noticed was a curvature of the little fingers At about 25 years of age the little finger began to become flexed, and then the same contracture extended to the ring fingers The female members of the family were not affected The father was 50 years of age and showed well marked contracture of the ring and little finger of both hands The son was 26 years old and showed *an earlier stage of the same process A male grandchild was still too young to show any of these symptoms The con*tracture attained its maximum about the age of 35 and then remained stationary

Mr E H SHAW showed 1 Two specimens of Carcinoma of the Breast The first was from a middle aged woman There was an irregular radiating growth, hard and white The nipple was retracted deeply below the surface Numerous hard glands had been found in the axilla and proved to contain growth The second was from a woman about 50 years of age It was ulcerating and fungating through the skin The tumour had been noticed about 18 months Several small soft glands in the axilla occurred, but were not affected by the growth 2 A specimen of Carcinoma of the Gall-bladder, Cystic Duct, and Main Bile ducts in the substance of the Liver It was a columnar celled growth, papillomatous for the most part The liver was bil[illegible] *It was removed from a middle aged woman who ha*[illegible] deeply jaundiced and wasted 3 A specimen of Hy[illegible] nephrosis There was a very small ureter which left th[illegible] upper part of the renal pelvis and bent sharply downwards, thus producing the obstruction which led to the condition *It was removed from a boy, aged 6 years, and was probably* congenital in origin

Dr R E JEWESBURY showed a case of Acromegaly. The patient, a woman aged 36, came to London when she was 16, and at that time was said to be small for her age She began to grow very rapidly when she was 19 Her hands and feet had become much enlarged and her face had altered, but she was not certain for how long these changes *had been present For the last three years she had been* subject to pain in her back and had become round shouldered She had always felt well until her last confinement in July, 1912, since then she had complained of always feeling tired and was often drowsy, *and also suffered a good deal* from dyspnœa on exertion She was free from headache, slept well, but often snored at night Her hearing and sight were good The appetite was normal and she was not unduly thirsty Menstruation was regular One sister was said to have large hands The patient presented a typical acromegalic appearance The face was markedly enlarged and elongated, the lower jaw was lengthened and the lower teeth projected beyond the upper, also the teeth were spaced *A plate was worn in the upper jaw, but the "bite" was bad* The skin of the face was coarse and hung in folds below the eyes; the lips were thick and the lower one protruded The tongue was somewhat enlarged and fissured The hands were much enlarged, especially in breadth, the fingers were increased in length as well as breadth The feet were much enlarged, but not to the same extent as the hands There were marked scoliosis and kyphosis in the lower cervical a [illegible] was pushed forward, [illegible] exceedingly irregular [illegible] howed some hypertrop [illegible] normal and there was no diminution of visual fields The thyroid gland was very definitely and uniformly enlarged X ray examination by Dr W Ironside Bruce showed very marked enlargement of the sella turcica and absorption of the posterior clinoid processes The urine, normal in amount, contained no sugar

Dr JEWESBURY also showed a case of Pneumothorax The patient, a boy aged 5 years, was admitted to the Victoria Hospital for Children for dyspnœa Four months ago he had measles and bronchitis followed by scarlet fever. Later his mother noticed that he "seemed very short of breath," and she brought him to the hospital He had had no previous illness and the family history was good On examination the boy was healthy looking and the general [illegible]

not move with respiration Vocal fremitus was absent over the right side The percussion note was hyper resonant all over the right chest, the liver dulness was diminished, and there was resonance between the left sternal edge and the cardiac dulness On auscultation the breath sounds were much diminished and distant all over the right side Coin sound obtained Over the left lung the breath sounds were somewhat exaggerated, nothing else abnormal was detected The heart was displaced very much to the left, the apex beat was in the fifth space, 1½ inches external to the nipple line, *and the area of cardiac dulness was much diminished The heart sounds were normal The liver was pushed down.* Radiograms of the chest by Dr Stanley Melville were shown

Mr A E BARKER showed specimens of a Remnant Tumour of the Umbilicus The original tumour was about the size of a small grape, and was seated in the umbilicus of a woman, where it had been noticed for some months. It was growing harder, and the skin over it was slightly discoloured It was widely removed by Mr Barker in September, 1908, between two curved incisions opening the abdomen The peritoneum between the incisions was removed with the piece of skin containing the nodule The usual method of closure was employed and absolute primary union resulted A section showed the structure of the primary nodule In the midst of fibrous tissue were seen tubular structures divided transversely or obliquely. These were lined by subcolumnar epithelial cells like some tubular glands. In some parts the tubules were surrounded by looser submucous tissue. These structures were scattered through the nodule, always fairly defined and not infiltrating surrounding parts. The patient was not seen again until January last, when she reappeared, saying that she had for some time felt a small nodule of the size of a pea inside the left anterior iliac spine, which was occasionally slightly painful. On examination this was felt to lie in the subcutaneous fat, but to produce a little puckering of the skin when lightly pinched. It was removed shortly after by Dr. Frank Hinds, of Worthing, who was kind enough to send the specimen to Mr. Barker. A section showed the structure to be practically the same as that of the original nodule except that there was more fibrous tissue around the tubules. The relation of the secondary nodule to the primary seemed therefore to be established by the microscopic examination and the clinical history. That the original nodule was a neoplasm arising in a remnant of either the urachus or vitelline duct seemed beyond doubt. That it had recurred in the abdominal wall some 3 inches distant after free removal of the original growth of course aroused the suspicion of malignancy. Growths in or about the umbilicus derived from these fœtal remnants, though rare, were well known and had been recorded. The only other one which Mr. Barker had seen occurred about the same time. It was much larger and attached to the transverse colon which was excised with it. The patient made an excellent recovery. The tumour on section contained a white, firm mass of sebaceous material, about the size of a large grape, in dense fibrous tissue. The specimen after being exhibited on several occasions was lost at hospital, and no microscopic sections had been preserved. In the enormous surgical material of London it seemed probable that similar cases had been met with, and it was hoped that this short note of two cases might lead to their being mentioned.

Mr. L. E. C. NORBURY showed a case of Malformations of Head and Face. The patient, aged 3 months, exhibited (1) accessory auricles, (2) left macrostoma, (3) complete occlusion of the anterior fontanelle with an irregular bony formation in this region, (4) deformity of the nose, and (5) corneal opacity of the left eye. There was no history of other malformations in the family.

HUNTERIAN SOCIETY.

The Uses of Tuberculin.

A MEETING of this society was held on April 9th at St. Bartholomew's Hospital, Mr. A. H. TUBBY, the President, being in the chair.

Dr. NATHAN RAW (Liverpool) opened the resumed discussion on the Varieties of Tuberculin and their Value in Treatment.[1] He had treated 1036 patients suffering from the various forms of tuberculosis in the wards of Mill-road Infirmary and elsewhere, and his general impression was most favourable. The localised forms of tuberculosis responded more readily to tuberculin than cases of pulmonary tuberculosis with a general systemic infection, and many localised cases were completely cured by its use. He thought that all cases of pulmonary tuberculosis in the first and second stages should be treated with tuberculin in addition to ordinary sanatorium measures. He invariably treated his cases by cross-vaccination. In his experience, pulmonary tuberculosis, being most frequently an infection by human tubercle bacilli, was best treated by a tuberculin prepared from bovine bacilli; and *per contra* the localised forms of tuberculosis, being frequently due to bovine bacilli, showed better results with human tuberculin. Bovine tuberculin was less toxic and less irritating, and was not inclined to produce general reaction, so that even the most sensitive patients could tolerate injections of bovine tuberculin, where the other injections cause reactions and discomfort. As to dosage, immunity should be established very slowly and with moderate doses. His practice was to commence treatment with 1/10,000th mg. by weight of dried bacillary substance, slowly increasing the dose week by week to a maximum dose of 1/100th mg., this maximum dose being repeated as long as need be. He never exceeded it, and found the results most satisfactory. He emphasised the need of the greatest possible care and watchfulness, and held that the treatment should be employed only by a physician of experience and special knowledge of tuberculin. He considered it a remedy of the greatest value, especially in early cases and where the deposit of tubercle was localised, as in one apex or a lymph gland or single joint, but where tuberculosis was disseminated and complicated by secondary infections little good was to be expected. It ought, however, to be tried in every suitable case, as it certainly limited the spread of the disease.

Dr. HINGSTON FOX had used tuberculin for some years among private patients, in coöperation with their medical attendants. He at first gave it by the mouth, but the results were uncertain. The largest dose he had as yet given subcutaneously was one half mg. of T.R. The tuberculin inoculation test was now commonly used, but the inflamed condition set up in a latent lesion did not always subside easily. He related two cases in illustration of this test; in one of them the temperature remained above normal for three months, and a still longer period of rest in bed was needed. There were many other means of diagnosis, and he submitted that the inoculation test, on account of its risk, should be used only in exceptional and obscure cases. He hoped there would be a pronouncement on this point in the profession, else the valuable tuberculin treatment might be discredited by its association with the test. Moreover, in his experience the therapeutic doses provided a test in themselves; beginning with a minute dose, we could increase this until a perceptible reaction appeared, local, general, and focal; if this was repeated, it afforded good evidence that a tuberculous lesion was present. Dr. Fox asked the experience of others in the use of tuberculin for affections of the larger joints. He had found the treatment in a case of early hip-joint disease in an adult difficult and slow; a very small dose only was tolerated and only at long intervals.

Dr. R. A. O'BRIEN, speaking purely as a laboratory worker, had always failed to understand the differences in action of P.T. and T. in the treatment of tuberculous disease, because the two preparations were tested against the same standard and their toxicity for the tuberculous guinea-pig was the same. The outcome of a severe reaction was really to desensitise. If a lethal dose of tuberculin—e.g., 0·1 c.c.—were injected into a tuberculous guinea-pig it might die in, say, 24 hours, and post mortem the foci of disease would be in a condition of extreme congestion, but if the dose were just sublethal the animal would survive the very violent reaction and would probably live as long afterwards as other members of the same batch of tuberculous guinea-pigs. In other words, the severe reaction caused by a sublethal dose of tuberculin did not seem to induce any exacerbation of the tuberculous process or shorten the animal's life. Moreover, it would now be able to stand a dose considerably larger than the original lethal dose without fatal result. The practice of "cattle-faking" against tuberculin injections depended on this principle. There were three great problems facing the clinician. The first was—Can we immunise against tuberculosis? The answer was in the negative. There was no form of tuberculin, or of anything else, which could confer complete immunity against tuberculosis except actual infection with living bacilli of moderate or low virulence. A cow might be immunised against bovine tubercle by infection with the human bacilli. And, more than this, the production of tuberculous disease in one eye by infecting it with living bacilli caused a definite degree of immunity to a subsequent inoculation into the other eye. The second question, whether we could diagnose the existence of tuberculous disease by specific tuberculin tests alone, must also be answered in the negative. In sensitive animals, such as the guinea-pig, a reaction of tuberculin was, it was true, diagnostic of active disease, but in comparatively insensitive animals, such as the horse, goat, or man, a reaction only meant that the subject then had, or had previously had, tuberculosis. Speaking with all deference in a gathering of clinicians, he would say that in the absence of definite clinical signs, a positive tuberculin test in man meant active tuberculosis only when supported by persistent rise of rectal temperature following energetic exercise. As to whether we could prevent or foretell the existence of hypersensitiveness in a patient under treatment, this, he feared, was impossible The determination of complement-binding antibodies in the serum was no criterion, because they were found also in cases that were improving Agglutinins and precipitins certainly occurred in the serum, but we were not able to control the course of treatment by estimating them He would not refer to the much debated *question of the opsonic index further than to remark that it* was rare to find a phagocytosed bacillus in the natural course of tuberculous disease Serum containing comple [illegible] its power of [illegible] lucing a von [illegible] disease due [illegible] arrested, and [illegible] The suggestion that the phenomena of anaphylaxis were analogous to those produced by tuberculin was not, he believed, borne out by investigation. The phenomena differed widely both in their clinical manifestations and in the post-mortem picture A guinea pig sensitised by an injection of protein and killed a fortnight later by anaphylactic shock following the injection of a second dose of the protein, died within a few minutes or in one to two hours owing to such a constriction of the bronchi that air could not pass to or from the alveoli A tuberculous guinea pig injected with tuberculin did not die for at least three to four hours and did not show the characteristic distension of the lungs Moreover as Dale had recently demonstrated the uterus of a protein sensitised guinea pig when suspended in a bath of Ringer solution contracted if a very small quantity of the sensitising protein was added to the solution and was thereby desensitised to a further dose of the protein The speaker had recently tried to obtain similar reactions with the uterus, but whether the guinea pigs were sensitised with tuberculin, bacillary emulsion, or various bacillary extracts he could get no definite contraction of the uterus followed by desensitisation after the addition of old tuberculin or bacillary extracts, nor did the uterus of the tubercular guinea pig show any such response so that here again there was a wide divergence between the phenomena of protein anaphylaxis and those of the tuberculin reaction

---

[1] THE LANCET, April 5th, 1913, p. 965.

Dr J K PATRICK gave his experience in a tuberculosis dispensary It agreed with Dr Raw's experience, that bovine tuberculin gave the best results in pulmonary tuberculosis and *vice versâ* He had treated lupus by tuberculin and had found the results of diagnosis by von Pirquet's reaction pretty good in this disease He had had good results of treatment in early cases of pulmonary tuberculosis

Dr A. BUTLER HARRIS discussed the treatment of tuberculous joints by tuberculin He believed that if the joint was put at rest in an early case the tuberculin treatment helped

Dr ARTHUR LATHAM, in replying feared that Dr Butler Harris's hope was not to be realised in the immediate future He agreed that dispensary treatment with intensive doses was overdone, but every method should be tried adequately so that under the sanatorium benefit sufficient data could be obtained for comparison He was surprised that Dr Raw used only doses varying in size from 0 0001 to 0 01 mg He would have supposed that an initial dose of 0 0001 mg would have caused a reaction in many of the cases described His impression was that immunity became greater and relapses less frequent as larger doses were used He was not convinced by Dr Raw that human tuberculin should be used for infections with the bovine bacillus and *vice versâ* or that tuberculin often diminished the necessary length of [illegible] gave the necessary stimulus [illegible] their own He emphasised [illegible] value in cases where auto-inoculation was frequent irregular, and uncontrollable He did not believe in using the subcutaneous test wholesale A focal reaction was the only one of clinical value, but even it held sources of error It could not be relied upon in itself, and the deductions drawn from its effects should always be considered side by side with any evidence obtainable by other means As to the value of the therapeutic test—of noting, for diagnosis, the effect of working gradually upwards from a small dose—he had treated with tuberculin certain cases, chiefly of anæmia with slight fever in young women, in which there was a strong suspicion, but no absolute proof, of tuberculosis, and had found a more rapid fall of temperature and improvement in the condition of the blood than was usually obtained by the ordinary remedies In such cases the marked improvement under [illegible] the condition was tuberculous [illegible] differences in toxicity of human [illegible] e was not convinced that they differed as much as some authorities held With the exercise of sufficient care he had found that reactions seldom followed the use of T R, even when doses as large as 5 mg were eventually injected The length of time that dilutions of T R had been made greatly influenced their toxicity and therapeutic efficiency

Mr FRANK CURRY demonstrated the preparation of the various tuberculins and their characteristics

The PRESIDENT, after thanking those who had taken part in the debate spoke of cases of tuberculous spine treated by tuberculin He now knew that the reason why this treatment was unsuccessful was that these cases were purulent and caseous from the very first

---

LIVERPOOL MEDICAL INSTITUTION —A meeting of this society was held on April 10th, Mr Robert Jones, the President, being in the chair —Dr Edward Malins, of Birmingham, presented to the society a portrait of his father, Samuel Malins, who died in 1843 and who had been a lecturer in midwifery in the Liverpool School of Medicine, and one of the earliest members of the society —On the proposal of Sir James Barr, seconded by Mr T H Bickerton, the thanks of the meeting were cordially given to Dr Malins for his most interesting donation —Mr R W Murray read a note on an Operation for Undescended Testicle At least ten different methods of treating the condition were described by various authorities There was always much difficulty in keeping the organ in the scrotum Mr Murray opened the canal, exposed the testicle, hernial sac and vas deferens at the level of the external ring, the sac was transfixed and cut across but the lower part was left attached to the testicle Then all the structures attaching the testicle were cut across between two ligatures and the testicle and sac were placed in the scrotal bed The immediate result was satisfactory, the testicle lived though its blood supply was cut off, it possibly supplied an internal secretion —Mr F T Paul said he had treated these cases by suturing the tissues in the canal across the cord to prevent it from being drawn up He did not sacrifice the duct —Dr Sydney M Whitaker showed a woman who had suffered from Rheumatoid Arthritis for 15 years All treatment proved useless except a 14 day fast, during which all pain left the joints A coliform autogenous vaccine also produced slight benefit As X rays showed intestinal stasis *an ileo-colostomy was performed* with marked improvement in the joints and general condition —Dr Walter C Oram read a paper entitled, 'The X Rays as Therapeutic Agents' The theories with regard to the production of the rays in the focus tube were briefly reviewed and the difference between hard and soft rays in their physical properties pointed out The measurement of the dosage by Sabouraud's pastilles was described and methods of ascertaining the penetrating power indicated Three essentials were laid down as necessary for efficient X ray treatment of any tissue first that the rays must reach the tissue to be treated in sufficient quantity, secondly, that they must be absorbed by the tissue, and thirdly, that the tissue must be susceptible to their action It was pointed out that the denser tissues of the body—the spleen, the thyroid, and the ovary—were far more susceptible to X ray treatment than those of less density such as the muscles, the kidney, and the brain Although the variation in density between one tissue and another might seem small, it was shown experimentally that these small variations caused considerable differences in the absorptive power for the rays Tissues varied much in their susceptibility, thus X ray exposures over the ovarian regions could bring about the suspension of activity of the ovaries, while the overlying skin, which had in the interval received a considerable dose was not affected The use of radiotherapeutic applications in malignant diseases eczema, psoriasis, leukæmia, goitre and other diseases was discussed —Dr F. H Barendt thought the X rays a valuable adjunct to treatment of skin diseases In some cases of tubercular disease good results were obtained, while in others the results were not satisfactory—the knowledge of the susceptibility of the tissues was wanting In cases of hypertrichosis X rays were inadvisable, and in ringworm this treatment should be left for the rebellious cases. In patches of localised eczema with intense pruritus X rays were of signal benefit.—Mr. C. Thurstan Holland thought the methods of measurement should be more accurate. In the treatment of malignant disease the method was of use if started early after a surgical removal; it then prevented recurrence, and secondary malignant nodules often disappeared. In menorrhagia the loss could be checked without risk. Pruritus was in many cases cured very rapidly.—Dr. R. W. MacKenna also spoke of the rapid action in cases of pruritus. He did not think the expectations with regard to malignant disease had been fulfilled.—Sir James Barr had used X ray treatment in cases of leukæmia, and had had rapid and striking improvement. Unfortunately, this had not been maintained, and when symptoms again appeared the X rays had no effect and all his cases had died.—Dr. Oram replied.

Reviews and Notices of Books.

Collected Studies on Typhus. Hygienic Laboratory, Treasury Department, United States Public Health Service, Bulletin No. 86. October, 1912. Washington: Government Printing Office.

THE Hygienic Laboratory of the United States Public Health Service has issued a bulletin containing collected studies on typhus. These papers, by Assistant-Surgeons Joseph Goldberger and John F. Anderson, discuss among other questions the etiology of "Tabardillo," the typhus fever of Mexico, and the conclusions which are arrived at are for the most part based upon results obtained by the inoculation of monkeys. At least two species of monkey, the Macacus rhesus and Cebus capuchinus, were found to be susceptible to direct inoculation with the blood from human cases of tabardillo, and blood taken from the monkey Macacus rhesus, thus infected, was used for the successful inoculation of a second monkey of the same species. Moreover, one attack of the disease in the monkey, produced by blood inoculation, induced a definite immunity to a subsequent inoculation with virulent blood, and when blood serum from a human case of tabardillo was passed through a Berkefeld filter it failed to produce disease when inoculated into a monkey. Before the observations of Nicole came to their knowledge conclusions were arrived at which were based upon other grounds than those derived from the laboratory. Thus an American non-immune came daily in contact with cases of tabardillo in Mexico, and on two nights slept in a bed which for three preceding nights had been slept in by a patient in the first three days of a well-marked attack of tabardillo, the bed clothes of which were then changed. No insects but fleas were found in the room, and the American non-immune escaped infection. The fact is also cited of the attendance of non-immune nurses on 30 cases of typhus occurring during some 23 months, in which none of the nurses were infected. These observations, coupled with the fact that the flea is ubiquitous, whereas the disease is usually limited to the lowest social class, led to the inference that the flea might be excluded. Again, the fact that the bed-bug is attached to houses and that there is no evidence that the tabardillo is a house disease led to the inference that the bed-bug is not concerned in transmitting the disease. A further point noted—viz., that the flea and bed-bug are common in the lowlands of Mexico, while tabardillo is only exceptionally found there—supported these inferences.

A separate paper is devoted to a discussion of the question whether Brill's disease, which is endemic in New York city, is identical with the Mexican typhus fever. Experiments on the rhesus monkey led to conclusions in the affirmative, and further, the inference was drawn that, inasmuch as the New York disease is of European origin, the typhus fever of Europe and that of Mexico are also identical. An interesting account is given of experiments made to determine whether body lice and head lice may become infected with Brill's disease, and whether the virus contained in the bodies of these insects is transmissible by subcutaneous injection of the crushed insect or by its bite. These questions are answered in the affirmative in respect of the body louse, and in the case of the head louse also in the affirmative, except that the ability of the latter to infect by its bite is spoken of with more caution as a "belief."

Experimental studies with the virus of typhus led to interesting conclusions. Thus, it was found that the blood of the monkey which has been infected may be virulent 24 to 32 hours after the return of the temperature to normal. In respect of the localisation of the virus, the evidence obtained favoured the view that the typhus virus is extracellular and free in the circulating plasma, and that the serum of virulent typhus blood is constantly infective, whether obtained from defibrinated blood or after clotting. The conclusion was arrived at as the result of a number of experiments that there was no evidence to show that the virus passed the Berkefeld filter, and in respect of two attempts which were made to filter the virus as it exists in the body of the louse, in one the monkey inoculated with the filtrate was subsequently found to be immune. The virus was found to retain its virulence after heating at 50° C. for 40 minutes, to be deprived of its virulence by heating at 55° for 15 minutes, to be probably deprived of its virulence by heating at 60° for five minutes, and to retain its infectivity after freezing for at least days.

A paper on Studies of Immunity and Means of Transmission of Typhus led to conclusions some of which may here be briefly stated. As many as 22·5 per cent. of rhesus monkeys possess at least a transient natural immunity, and probably 3·5 per cent. possess a permanent natural immunity. A well-marked typhus reaction confers an immunity that may be present after at least two years. The guinea-pig is, and a very small proportion of rabbits may be, susceptible to infection. The immunity conferred by an attack of typhus is specific. Typhus-immune serum obtained between the fifth and the fourteenth day of convalescence has protective value when injected simultaneously with, or within 48 hours after the inoculation of the virus, but immune serum obtained on the thirtieth day of convalescence probably has no appreciable protective influence. When immune serum and virus are inoculated simultaneously no immunity results. When the immune serum is injected 48 hours after the virus, an immunity, probably active in nature, may perhaps result. The therapeutic value of immune serum is at best slight. Vaccination with heated crushed-lice suspension was attempted with a negative result. The bite of the body louse may perhaps be infective within four days after the infecting feed. Attempts to transmit typhus by means of the bites and subcutaneous injection of crushed bed bugs were unsuccessful. The buccal and pharyngeal secretions of typhus were not found to be infective, and therefore droplet infection plays no part in the transmission of the disease.

Diseases of Children. By BENJAMIN KNOX RACHFORD, Professor of Diseases of Children, Ohio-Miami University of Cincinnati. London and New York: D. Appleton and Co. 1912. Pp. 783. Price 25*s.* net.

AS a writer on medical subjects Dr. Rachford is probably little known in this country, but his book on the diagnosis and treatment of children's diseases now before us should serve as an introduction which will invite closer acquaintance. This new publication seems to strike a happy mean between the large text-book which is employed only as a work of reference and the small compendium to which the student pins his faith in anticipation of his professional examinations. In a book so practical it is curious that many really important points in connexion with the etiology and pathology of tuberculosis and syphilis should have been omitted, and that there should be no mention at all of such rare, though important, diseases as achondroplasia and cleido-cranial dysostosis. Upon the view that immunity to tuberculosis, the prerogative of the healthy adult, is not due to non-infection, but to effective and timely inoculations with the specific bacillus, Dr. Rachford's statement that, "other things being equal, the danger of contracting tuberculosis is in direct proportion to the frequency and size of the dose of the contagion," cannot be regarded as a satisfactory interpretation of the facts.

The chapters which are concerned with the general management and hygiene of infancy are practical and to the point, and the general principles formulated therein for the instruction of students are founded on a basis of which few will disapprove. As regards feeding the author says: "It follows, therefore, that the percentage method of feeding which gives to the infant the relative quantities of fat, carbohydrates, proteins and salts it needs, must ever remain the basis of scientific feeding, and that in using this method we should, to secure fairly accurate quantities, conform, within certain limits, to the calorimetric standard, and should, to prevent or correct gastro-intestinal disturbances, change the percentages of the various food ingredients to conform to the digestive capacity and food idiosyncrasies of the individual infant." Though somewhat involved in construction this statement represents, in our opinion, a very judicious summary of the ends at which scientific feeding should aim. It conveys a thinly veiled admonition to those who ridicule the principles of scientific accuracy and should tend to curb the enthusiasm of those who would push the refinements of the percentage method beyond the bounds of reason. Again, with respect to the calorimetric standard, we are reminded that however useful the formulæ may be in guiding us out of the reach of gross error, in blindly following its teaching we run a risk of starving or overfeeding infants who are subjects of idiosyncrasies of metabolism.

In another chapter a very excellent account is given of that troublesome neurosis "thigh-friction," or, as the author calls it, "*pseudo-masturbation.*" The practical advice which is offered with respect to its prevention and cure will be gratefully acknowledged by practitioners who have to deal with these intractable cases. We cannot, however, agree with the distinctions which the author draws between this the pseudo form and the true form, which occurs at a later period of childhood. The two conditions appear to us essentially the same, although accompanied by different psychological phenomena, and in spite of the fact that in the so-called pseudo form the orgasm is incomplete and the testicular secretion absent. The subject of enuresis is also dealt with in a thoroughly practical manner, and its dependence on a triad of factors—namely, the degree of stability of the centres concerned, the degree of concentration of the activating qualities of the blood, and the number and the intensity of the reflex sources of irritation—is well indicated. This philosophic conception of a very complicated condition compares very favourably with the bald etiology and crude pathogenesis which we usually find ascribed to it in text-books on the subject of children's diseases.

Although there is little that is original or new in this volume, there is very much that is new in the way old and familiar facts are presented. We regard Dr. Rachford's book as well worthy of the attention of English readers.

Studies in Cancer and Allied Subjects: Pathology. Conducted under the George Crocker Special Research Fund at Columbia University. Vol. II. New York: The Columbia University Press. 1912. Pp. 267. Price 21*s.* net.

IT appears that Vol. I., which will give a "General Report on the Present Status of Cancer Knowledge," is "in preparation." Meantime Vol. II. is before us—a quarto with stately broad margins to its well-printed matter, to which Professor W. G. MacCallum writes an introductory chapter. The anatomy, structure, and clinical history of tumour growth have been worked at by thousands of investigators, but when we come to the question of the causation little advance has been made, as pathologists and clinicians allow regretfully. Even our knowledge of the relation of the cells of a tumour to the tissue in which they begin their growth is still very uncertain. Of the current theories none is satisfactory. "To determine the etiology of tumour growths, the causes of the growth of cells in general, and the factors which underlie the increase in the energy of their growth, as well as those which limit or hold it in check, the last ten years have contributed marvelous things." The next ten years may tear aside the whole veil. Such is the forecast of the optimists.

The report contains in all 27 articles reprinted from various journals. Fourteen at least of these articles are contributed by Dr. Isaac Lewin, either in his own name or in conjunction with others. Amongst these contributions are Resistance to the Growth of Cancer in Rats by injection of Autolysed Tissue, Cancer of the Uterus, based on Clinical Statistics, Immunity to Growth of Cancer induced in Rats by Treatment with Mouse Tissue, Immunity in Cancers of the White Rat, Cancer among the American Indians, Heredity in Cancer in the White Rat, Metastases after Intra-vascular Injection of Tumour Emulsions, and the Mechanism of Metastases in Malignant Tumours, Specific Stroma Reaction, and Hormones and New Growths. Some of the contributions are very short, extending to but a page or two, and naturally there is some amount of repetition. Dr. Robert A. Lambert and his collaborators are responsible for contributions dealing with parabiosis of rats and mice, growth *in vitro* of transplantable sarcomas of rats and mice, migration of sarcoma cells growing *in vitro*, phagocytic inclusion of sarcoma cells *in vitro*, characteristics of growth of sarcoma and carcinoma cultivated *in vitro*, cultivation of tissue in plasma from allied species, and as a method for the study of cytotoxins. Dr. R. T. Frank discourses on the causes which produce growth of the mammary gland and the functions of the ovary. A great stride was made, in fact a new era was opened up, in the investigation of the question of new growth formation when Hanau, Moran in 1889, and with still more precision Jensen, and Loeb in 1901, transplanted carcinoma and sarcoma of white mice and rats into other animals of the same species. These researches showed the difference in the susceptibility of different animals to the growth of an implanted tumour.

Some interesting details are given in the paper regarding Cancer among the American Indians. It is well known now that cancer may occur not only in every human race but in nearly every species of vertebrates. Cancer of the penis is extremely frequent among the Hindus, while not a single case is met with among Mohammedans. The fact is, of course, attributed to the circumcision practised by the latter. Cancer is rare among Indians. As to Heredity in Cancer of the White Rat, the work was begun in 1910 by Dr. Lewin and his collaborators, and the results so far "seem to be extremely suggestive." It is much the same with Immunity in Cancers of the White Rat. A mouse tumour through a sojourn in the rat "takes" in a small percentage of inoculated animals, and this percentage increases in subsequent generations. Evidence is brought to show that immunity to cancer growth, but not to tumour grafting, is caused, not by differences in intracellular nutrition, but by an active inhibitory influence of the organism of the host on the cancer cells. Other studies were directed to the search for evidence of the true nature of this inhibitory influence, and when we inquire what is the result it is stated that "immunity to cancer growth is due to an active inhibitory influence of some substance present in the body fluids of the immune host and not to any purely cellular activity," and it is concluded that "it must be very similar to, though not identical with, immunity in bacterial diseases." In regard to metastases of malignant growths, the fact that carcinoma forms metastases in lymphatic glands is due, not to the difference of transportation in the carcinoma and the sarcoma, but to the specific affinity between carcinoma cells and the cells of lymphatic glands. Sarcoma cells may find easy access to glands, but may not find a favourable medium for their proliferation. As to the later studies on Heredity in Cancer the conclusions arrived at by Dr. Lewin are not to be considered in any way final; indeed, the author points out that his more recent studies show that the conclusion reached by him that hereditary disposition has no influence on cancer may have to be revised in the future. The difficulty in all these papers is to get to facts, and this paucity of facts makes it so difficult to give a connected summary of genuine reliable results. The whole is suggestive of the phrase "to be continued," but it is fair to allow that much of our knowledge in these fields is transitional.

Most interesting contributions are the accounts of growth *in vitro* of transplantable sarcomas of rats and mice by Lambert and Hanes. Harrison cultivated tissues of the frog embryo in lymph, but with the substitution of blood plasma for lymph by Carrel and Burrows in 1910 the method was simplified, and sarcomas, both human and avian, have been cultivated in this fluid, and the migration by amœboid movement of sarcoma cells has been observed, obviously a phenomenon of importance in relation to the problem of the spread of malignant growths in the body. An interesting account is given of the character of growth, proliferation, and karyokinesis of sarcoma and carcinoma cells *in vitro*. Both cells are also actively phagocytic. Nor need such cells be cultivated in plasma obtained from the same species in which the original tumour grew. Rat sarcoma can be cultivated in the plasma of an alien species such as a mouse or a guinea-pig. The same method has been used for the study of cytotoxins. In view of the well-known experiments of Claypon and Starling on breast hypertrophy in pregnancy from "breast hormones" the paper by Frank and Unger is particularly interesting. They conclude that a breast hormone "elaborated by the fetus" has not been demonstrated and must be considered purely hypothetical. In his paper on the Function of the Ovary Frank remarks that this subject seems hardly appropriate in a collection of monographs dealing with the cancer problem and proceeds to justify its inclusion.

It will be seen that the monographs record the endeavours of numerous eager observers to reach a definite goal, and consequently in the march of events many of the conclusions must be only tentative and suggestive. It is well to have the researches on such an important subject incorporated in one volume, for this will render the methods of research, as well as such conclusions as may safely be relied on, accessible to the numerous workers in the pressing problem of cancer.

LIBRARY TABLE.

Manual of Chemistry. By W. SIMON, Ph.D., M.D., and DANIEL BASE, Ph.D. Tenth edition, thoroughly revised. London: Baillière, Tindall, and Cox. 1912. Pp. 774. Price 15*s.* net.—In previous references to this work we have expressed a favourable opinion of it, and the fact that it has reached a tenth edition is proof of its appreciation by those readers for whom it was primarily written—viz., students of medicine, pharmacy, and dentistry. It presents a thorough treatment of the subject so far as the special requirements indicated go, and each successive edition has kept pace with modern developments. We are glad to notice in the present edition that the physical aspects of chemical phenomena, which are increasing in importance as regards physiological study day by day, have received conspicuous attention. There is, for example, a new chapter on electrolytic dissociation, in which are considered the origin of the theory of ionic equilibrium, ionisation of acids, bases, and salts, reactions on the ionic basis, hydrolysis, and so forth. In fact, the authors have approached the subject from beginning to end with an eye to the directions which modern teaching and interpretations are taking. The ground covered is a striking feature of the work, having regard to the space at the authors' disposal. Thus the student is introduced in the first section to chemical physics, next to principles of chemistry, then to non-metals and their combinations, then to the metals with their combinations; these are succeeded by sections on analytical chemistry, the carbon compounds or organic chemistry, and, finally, physiological chemistry, which includes a very useful chapter on proteins, digestion, milk, and urine. The illustrations, of which there are 82, are well executed, and they include one coloured spectra plate and eight coloured plates portraying 64 chemical reactions. Our favourable opinion of this book is advanced further by a consideration of the very careful and up-to-date work which has been devoted to this last edition. The authors have succeeded in providing students of medicine, dentistry, and pharmacy with a book which eminently suits their particular needs at the commencement of their studies.

Clinique Médicale de l'Hôtel-Dieu de Paris. Par le Professeur A. GILBERT, Membre de l'Académie de Médecine. Paris: J. B. Baillière et Fils. Pp. 312. Price 12 francs.—The medical world has been familiarised in the past with the careful and painstaking work performed in the wards of the Hôtel Dieu at Paris by the classical lectures of Trousseau and his pupil Dieulafoy. The present work by Professor A. Gilbert carries on the tradition of the Hôtel Dieu for accurate and clear exposition, with the help of all the modern aids to diagnosis, physical, chemical, and bacteriological. It contains the clinical lectures given during Professor Gilbert's first year of teaching, 1910–11, with the coördinated assistance of chefs de clinique, chefs de laboratoire, and various specialists, which is so noteworthy a feature of the Hôtel Dieu. The opening lecture, which occupies the first 36 pages, gives an illustrated historical account of this ancient hospital, which is said to have had its inception in the ninth century. This is followed by one on the general principles of therapeutics. These are followed by seven lectures on chronic nephritis, three on Raynaud's disease, two on glandular tuberculosis, four on acholuric icterus, and one on essential paroxysmal hæmoglobinuria, which give ample opportunities, well taken, for displaying the services of radioscopy, blood pressure readings, blood and urine examinations, bacteriological investigations by staining and culture, and so forth.

THE LANCET.

LONDON: SATURDAY, APRIL 26, 1913.

The Health of the Rising Generation.

MR. PEASE, in the House of Commons recently, on a vote to complete the sum of £14,000,000 for his department, made the annual statement of the President of the Board of Education, and that much of what he said was of the first importance to the medical profession will be gathered by our report of his statement last week. The children in the elementary schools of this country, on whose upbringing no less than £11,000,000 of the £14,000,000 in question is spent, are largely in the charge of the medical profession, so general have been the pathological defaults revealed by the inspection of school children. In one important direction the number of these children is undergoing a substantial reduction. In 1903 there were 613,000 infants between three and five years attending elementary schools, while last year the number had dropped to 332,000, a reduction of 45 per cent. in ten years. This reduction will not in the end lighten the burden to the ratepayers. It is true that inquiries show that the State education in the infants' department in the past has not been conducted in the best interest of the smaller children, while MR. PEASE'S readiness to adopt the advice of the Select Committee which, some four or five years ago, reported that, given a mother who could do her duty, home was the best place for tiny children, was applauded by the House of Commons. But the terrible question of environment prevents us from looking forward to the time as being very near when to leave the infant with the mother is necessarily the preferable course from the point of view of public health. Nursery schools on a large scale seem to form the proper way of dealing with the difficulty, and some such provision will probably be made.

A direct appeal to medical interest is now regularly offered by the Board of Education when reference occurs to the vast efforts for the removal of those physical disabilities which preclude the children from receiving proper benefit from State education. Simple and obvious as the proposition is, that the object of the education given to the child should be to turn him out from school sound physically as well as mentally—so that, on the one hand, he can take full advantage of what he has learned and apply it to the real education of the future, namely, the conduct of life, and, on the other hand, can gather from practical experience how to look after his own health in ordinary circumstances—simple and obvious as this proposition is, it is not often stated in so many words by educational authorities, and it is far from regularly acted upon in this country. It is necessary that the public should understand that the physical state of children of school age is not satisfactory, and it is from the medical profession that their information should be obtained, if only because the statements on the subject made by many energetic lay workers are too often damaged by over-strenuous advocacy. Wild talk about national degeneracy is actually harmful to the cause which it is intended to help, producing in the public the impression either that things have got beyond cure or that wilful exaggeration is being used with a view to frighten the country into paying for something fantastic or sentimental. MR. PEASE, it is well known, is himself a practical exponent of the theory that to enjoy physical training and exercise helps the young man to be a good citizen; and while, as ever, the main difficulty of obtaining for our State school children the healthy body in which to develop the healthy mind is presented by their home circumstances, we must on no account wait idly doing nothing because the housing question largely baffles solution. Much may be done for the physical good of our young by a judicious use of organised recreation during school hours. This must not be taken to condone that passionate devotion to sports which to our mind has been of recent years a source of national loss and a wasting of valuable energy. We are glad to see on all sides a revolt from this worship of athletics; but the onus upon all to assist the rising generation to grow up strong and healthy is felt very keenly by many who, none the less, resent the time spent by the population in playing games and, worse, in watching games being played.

The system of medical inspection of the State school children has now been in working order for some time, and has brought to the public attention the alarming amount of disease present, and present apparently with the tolerant acquiescence of a majority of the parents. As many as 50 per cent. of the children of school age have been found to suffer from serious decay of their teeth, while 10 per cent. display proofs of malnutrition, not all of whom owe their plight to destitution any more than to neglect or bad management. We lay no stress upon the occurrence of other preventable pathological conditions among the school children, for as yet we cannot estimate closely the measure of the evil. Within rough boundaries its extent is known to our readers and it is also known that there has been great difficulty in securing that medical treatment should follow upon medical inspection. In no place has the improvement of methods in this direction been greater than in London, where the difficulties in the organisation of medical treatment have been found to be so grave, and where they are now being faced with some success. The essential thing from the medical point of view seems to be to secure as far as possible that the regular attendance of the children should not be nullified by the fact that when their time of education is complete there is no particular opening in life for them, no continuation or trade schools established which would help them to make some use of the education which they have received. We have no doubt whatever that the establishment of such schools, with the provision that this would imply of regular and skilled labour, would work incalculably to the improvement of the public health of the next generation. The general feeling is becoming manifest in this direction. Last week the PRIME MINISTER received favourably a deputation, introduced by Prince ALEXANDER of TECK, composed of members of the council of the British Boys' Training Corps, an institution which proposes to provide systematic military and industrial training for boys after leaving school. Undoubtedly this institution, which is well worth pecuniary support, has for its main object the preparation of an intelligent and skilled class for the army. But what can be done for potential recruits, or for those whose manners have already earned them a visit to an industrial school, ought to be done in some large measure for the general school population.

◆

The Royal Medical Benevolent Fund.

WE have called the attention of our readers on several occasions already to the public dinner of those interested in the work of the Royal Medical Benevolent Fund and its associated Guild, which will take place on Wednesday next, April 30th, at the Hotel Cecil, London, under the presidency of H.R.H. Prince ARTHUR of CONNAUGHT. We hope sincerely that the result of the dinner will be the raising of a substantial sum of money for most deserving objects. No one can read the brief summaries that we publish from time to time of the cases which the committee of the Fund is able to relieve without recognising that here is an organisation worthy of all support, ministering in the most direct way to the needs of necessitous members of the medical profession, or to the widows and children of those of our colleagues whom death has overtaken ere they had made provision for their dependents. The Royal Medical Benevolent Fund is now in the seventy-seventh year of its working, and has granted over £160,000 to its numerous beneficiaries. At first it was a small and struggling organisation, but now its annual distributions in money amount to thousands—in 1912 nearly £6000 were granted in donations and annuities—while its auxiliary branch, the Ladies' Guild, is coming to the aid of numerous families where the provision of clothing, and the assistance of payment in school fees may make all the difference in the fight with poverty, between complete surrender and successful struggle We have no hesitation, therefore, in bringing the objects of the Fund before our readers in a prominent way, at a time when pecuniary support will be particularly acceptable to those responsible for the organisation of the Fund. The Fund is deserving of all the help that members of the medical profession can afford to give it. It has been throughout splendidly and economically administered, and is doing a great work. It is sincerely to be hoped that the opportunity of the coming banquet will be taken by many laymen to contribute to the Fund. The public supports only in the barest way the charities of the medical profession, and yet no section of the population has a more close and direct claim upon its generosity. The medical life is a hard one, the number of those who follow it who are in a position to make large donations in aid of their less fortunate brethren is very small, and the failure of many medical men to leave at their death adequate support for their wives and children is but rarely due to improvidence. The medical man marries young—in general practice this is an almost invariable rule. His chances of securing a good return in money for his efforts are jeopardised by an extraordinary number of fortuitous circumstances against which no precautions are of much avail, and these precautions are absolutely ruined by bad health. A general practitioner is often some way advanced into middle life before he can set aside from his earnings any regular sums for investment, or pay any substantial premiums to a life insurance company. To say that in these circumstances those dependent upon him would not be able, in the case of his untimely death, to retain the social and educational advantages which they had enjoyed during his life is entirely to understate the case. If no greater hardships than such were in question our plea for the support of the Royal Medical Benevolent Fund, though it would none the less be due, would be of a much less urgent nature. What we want to bring home to our readers, and through them to the public, is that in many cases a medical man through no fault of his own, and his dependents certainly through no fault of theirs, fall into absolute penury, in which plight nothing may stand between them and hopeless misery but such grants as the *Royal Medical Benevolent Fund* can make or that private benevolence may supply.

◆

Lind-af-Hageby v. Astor and Others.

THE lately concluded action for libel brought by Miss LIND-AF-HAGEBY will be identified by posterity when it consults the law reports with the name of Mr. ASTOR, the proprietor of the *Pall Mall Gazette*, in which paper appeared the outspoken and candid article by Dr. C. W. SALEEBY that gave rise to the recent unsuccessful claim for damages. The main issue, however, lay between the plaintiff and the author, and the actions launched against the proprietor, the editor, and the printer had to stand or fall according to whether Dr. SALEEBY succeeded in maintaining the position taken up by him in criticising the "antivivisection shop" in Piccadilly in the course of a review of a work by Mr. STEPHEN PAGET, the honorary secretary of the Research Defence Society. Dr. SALEEBY is, therefore, the person first to be congratulated upon the conclusion of the protracted trial brought at last to an end by a verdict for the defendants, although the expression of our satisfaction at his success must be taken to include Mr. ASTOR, Mr. GARVIN, and the printer of the *Pall Mall Gazette*.

The result was no doubt anticipated by all not blinded by prejudice who followed the evidence in the daily newspapers. The case was very fully reported, and naturally so, for the long-standing quarrel between the antivivisectionists and the exponents of scientific medicine is a matter of the first public interest. The daily reports have therefore rendered it unnecessary for us to explain at any length the questions raised upon the pleadings before Mr. Justice BUCKNILL, to describe the matter out of which they arose, or to recapitulate the incidents and features of a trial the wearisome length of which seems to require explanation

The prolixity was perhaps not altogether avoidable when the circumstances in which the case originated are considered and the nature of the observations into which Miss LIND-AF-HAGEBY read a personal libel upon herself. The enormous expense, however, of protracted litigation renders the importing into it of irrelevant matter a source of hardship to the party not responsible for its introduction, and the fact that LIND-AF-HAGEBY *v.* ASTOR became something like another Royal Commission upon experiments on animals must be held to be largely due to the consideration extended in our courts to litigants appearing in person, and such litigants do not suffer if they are women. Miss LIND-AF-HAGEBY certainly cannot complain that she did not have what sportsmen would call "a run for her money." She was occasionally stopped, it is true, but was able to inform the court, among other matters, of often-quoted opinions attributed to ROBERT BROWNING and TENNYSON, to RUSKIN, to the late Lord COLERIDGE, and to the late Lord BRAMPTON, the importance of which must fall to the ground when we find persons of equal intellectual fame and strength of character holding opposite views. We select this particular irrelevancy for special reference because we regard it as typical of sentimental reasoning. It is on a par with the cross-examination of Sir VICTOR HORSLEY, who was asked whether he was recently at variance with the majority of the medical profession. The suggestion intended to be conveyed was that because Sir VICTOR HORSLEY differed from some of his colleagues upon questions relating to medical politics, they would not endorse his opinions as to the utility of experiments on animals, or honour him as a great surgeon eminently qualified to assist any tribunal with his evidence on such a topic.

Even, however, with the aid of irrelevancy the trial just over does not appear to have advanced the cause of those who denounce all experiments upon animals. Neither the allegations put forward as facts, nor the opinions of medical witnesses appearing as experts for the plaintiff, contained anything that we have not heard before, or, for the most part, that cannot be found in the evidence which was not followed by the late Royal Commission in its report. The jury were told, as they may be told again, that HARVEY not only owed nothing to experiments conducted upon animals, but that he contributed nothing to science, being merely the man who embodied and put in order the discovery of others who made no experiments; that PASTEUR advanced science only "from his point of view" and by his treatment of rabies succeeded merely in increasing the number of cases of that fell disease; that no discovery of any value attributable to experiments upon animals was ever made by KOCH, whether with regard to tuberculosis, to pneumonia, or to tetanus; that Sir VICTOR HORSLEY has achieved nothing by experiments upon animals because the operations for which he claims utility are useless; that the action of such drugs as veronal, sulphonal, digitalis, antipyrin, and cocaine is in no way better understood from any investigation of their characteristics for which animals have been employed; that serum inoculation for plague in India has not only failed to lessen the ravages of the disease, but has actually increased them; and that experiments upon animals are not necessary to advance our knowledge of bacteriology. The reiteration of assertions like these, even when they are made under the sanction of an oath in the witness-box, does not perhaps do much harm. Such statements can be contradicted promptly by witnesses standing upon equal ground before the law. And when an issue is being fought in a court of justice, reasoning laymen are apt to inquire who are those who thrust forward strange doctrines. They weigh their names and fames in the balance against those of the men who so clearly and confidently declare them to be wrong. When this occurs it may be said with satisfaction that on the whole the progress of error is arrested, apart from the weight carried by a jury's verdict.

Of course, we do not suggest that everyone is convinced by the evidence of physiologists and surgeons whose names are household words in their professions. There will be many who will point to the medical evidence called by Miss LIND-AF-HAGEBY and to that of the various laymen whose social and other distinctions matter nothing when we consider to what their testimony was directed. There are also, we must always remember, persons from time to time found clinging to the time-honoured belief that the world is flat. No one is likely to convince a large proportion of Miss LIND-AF-HAGEBY's sympathisers and admirers that every word of her statements and suggestions is not true. They will continue to aver, as she with the support of others has averred, that experiments are conducted upon animals that are only nominally anæsthetised, and that "vivisectionists" perpetrate unnecessary acts of cruelty because—if any charity is to be accorded to them—their eagerness for their imaginary discoveries renders them oblivious of, and indifferent to, animal suffering. Fortunately, this kind of abuse defeats itself. The occasion of the trial has enabled those who are engaged upon scientific research to justify their position and to vindicate their good name; this has been observed with satisfaction by the public, who have had an opportunity to read in their daily newspapers the plain and forcible evidence given for the defence by Professor W. M. BAYLISS, Professor A. D. WALLER, Sir VICTOR HORSLEY, Dr. C. J. MARTIN, Dr. E. W. GOODALL, Dr. F. F. CAIGER, Dr. J. MACKENZIE, Dr. ALICE CORTHORN, Professor A. R. CUSHNY, Dr. W. H. EYRE, and Dr. W. BULLOCH. We give the general public credit for being able to judge whether this evidence was honestly and straightforwardly given, and whether it was in any way shaken by a plaintiff who had fully the usual opportunities for cross-examination, was mistress of her own side of the case, and who showed herself throughout the trial an able and dexterous advocate of her cause.

CIRENCESTER (GLOUCESTERSHIRE) HOSPITAL.—The Cirencester Hospital was formally re-opened on April 17th by Lady Bathurst. The old building has been brought up to modern requirements and a new wing has been added, which will increase the number of beds from 13 to 17. The cost of the undertaking was defrayed by the generosity of the late Mr. D. G. Bingham, who gave £2500 for the purpose. Mrs. Wilfred Cripps has subscribed £500 towards the endowment fund of the charity.

Annotations.

"Ne quid nimis."

YELLOW FEVER COMMISSION (WEST AFRICA), 1913.

THE Secretary of State for the Colonies has appointed Sir James Kingston Fowler (chairman), Major Sir Ronald Ross, Colonel Sir William Leishman, and Professor W. J. R. Simpson to be a Commission to study the nature and the relative frequency of the fevers occurring amongst the Europeans, natives, and others in West Africa, especially with regard to yellow fever and its minor manifestations. Mr. A. Fiddian, of the Colonial Office, has been appointed secretary of the Commission, and Mr. T. F. G. Mayer, West African Medical Staff, assistant secretary. In the absence of special reasons the Commission will not themselves proceed to West Africa, but local investigators will work under their direction at certain centres. As at present arranged those centres will be Freetown in Sierra Leone and Sekondi and Accra on the Gold Coast. The investigators at Freetown will be Major J. C. B. Statham, R.A.M.C., sanitary officer of the Command, and Dr. G. G. B. Butler, of the West African Medical Staff. Those at Sekondi will be Dr. H. S. Coghill, assistant at the Medical Research Institute, Lagos, and Mr. H. M. Hänschell, senior demonstrator at the London School of Tropical Medicine. Those at Accra will be Dr. G. E. H. Le Fanu, of the West African Medical Staff, and another. The investigation will be set on foot towards the end of April or early in May. Endeavours have been made to enlist the coöperation of all medical men practising in the British dependencies in West Africa, whether as Government medical officers or otherwise. The funds for this investigation will be provided by the West African Dependencies.

SPURIOUS FOAM.

WE called attention some time back to the fact that many beverages were made attractive by the addition of certain preparations producing a foam upon the surface of the fluid. The most frequently used substance for this purpose, we pointed out, was a preparation known as soap bark—quillaia saponaria—its property of producing a froth being due to the presence of the glucoside saponin. We entered two objections to the use of this substance in beverages. First, it is added to give to a fluid which is in reality flat, stale, and unprofitable, the appearance of healthy briskness. That is a deception which may succeed with uncritical palates in passing off an unworthy beer as sound. Secondly, although the quantity of saponin necessary for the purpose is small, yet it is equally without doubt a poisonous glucoside, and on general principles it is desirable to keep poisons out of liquids destined for human consumption. That saponin is not altogether an inert body is evident from the fact that its lather has been used to kill pediculi of the scalp, and further, though it appears to have been used as an expectorant in bronchitis, it is contra-indicated in inflammation of the intestines or stomach and in ulcerated conditions of the mucous membrane, while large quantities paralyse the respiratory vaso-motor centres. Our references to these facts in relation to the use of saponin in common beverages, such as mineral waters and beer, were generally discredited on the score that the quantity sufficient for giving a "head" was infinitesimal. In days, however, when the origin of many symptoms is obscure, it is well to have an eye to the possibilities of causation in the manifold resources of modern methods of manufacture. It is significant, at all events, that the use of saponin was some years ago prohibited in Austria, but a more recent step in the same direction, for doubtless very good reasons, has been taken by the Department of Health of the City of New York. In a bulletin issued for the week ending March 22nd last the use of soap bark in soda-water is prohibited. A preparation of soap bark (saponin), according to the bulletin, is used quite commonly in the country in the preparation of soda-water, in some kinds of "soft" drinks, and in fillings used by bakers. Soap bark contains, it is further stated, a poisonous substance, and the Health Department considers the use of a soap bark extract or of commercial saponin in foods or food preparations in any quantity whatever an injurious adulteration, and forthwith prohibits its use. We objected primarily to the false appearance of healthy effervescence which the addition of saponin gives to beverages because such an appearance implies a wholesome aerated condition of the fluid due to disengagement of carbonic acid gas. Next we raised an objection on account of the well-known irritant properties of saponin, though we were well aware that the quantity sufficing for the purpose was small. As will be seen, a complete endorsement of the views we expressed seven years ago occurs in the opening sentences contained in the weekly bulletin of the Department of Health referred to. They are as follows: "The average person who drinks soda-water, sarsaparilla, cream soda, root beer, and other so-called 'soft' drinks, probably imagines, if he gives any thought to the matter, that the creamy deep foam which tops his glass results naturally from the liberation of the carbonic acid gas therein contained. Such, unfortunately, is frequently not the case, the foam, especially when deep, white, and creamy, being sometimes produced artificially by the addition of a substance known as soap bark, various preparations of which are upon the market. 'Soap bark' is poisonous and markedly so, its toxic principle being sapotoxin. On this account the Department of Health has determined to prohibit its use, and henceforth if the cheaper grades of soda water, &c., do not present so attractive an appearance as heretofore, they will, at least, exercise no detrimental effect upon the community."

THE ARREST OF HÆMORRHAGE BY THE APPLICATION OF HORSE SERUM.

IN recent years horse serum has been injected hypodermically in the treatment of hæmorrhage due to diminished coagulability of the blood, such as occurs in hæmophilia, purpura, melæna neonatorum, and in operations in cases of long-continued icterus. A method which has been employed much less frequently is the local application of horse serum as a styptic. In the *Journal of the American Medical Association* of March 8th Dr. C. G. Levison has reported the two following cases. A man, aged 49 years, gave the history that he had suffered for several years from intermittent epistaxis which was cured only by removal of the turbinal bones. There was a moderate degree of arteriosclerosis. He had been suffering for some time from irritability of the bladder. Cystoscopic examination revealed a cyst at the internal orifice of the urethra, which was cauterised. At the time of the operation there was no hæmorrhage, but on the following night the bladder became distended with clots, which were evacuated with difficulty. Bleeding persisted for a week and then became profuse. When Dr. Levison saw the patient he was very exsanguine, and the bladder reached to the umbilicus and was firm from the presence of clots. Cystotomy was performed, and the clots were removed. The cystic tumour had been burned away, and a small bleeding area had been left. This was cauterised with the actual cautery, and the bladder was packed with iodoform gauze But the hæmorrhage never ceased for seven days, despite the application of various astringents—namely, tincture of iron, alum, epinephrin, and antipyrin, and the injection of horse serum The abdominal wound bled as persistently as the area in the bladder There was continuous oozing of bright red blood, and the patient's condition was growing exceedingly grave A flask of horse serum was poured into the bladder Almost at once the hæmorrhage ceased, and it did not recur *In the second case* the patient was a woman, aged 45 years, who had suffered for three months from persistent but not intense jaundice She had an enlarged gall bladder The coagulation time of the blood was eight minutes *Carcinoma involving the* biliary passages was diagnosed The gall bladder was exposed, and about 8 ounces of dark green bile, of the consistence of tar, were removed Cholecystenterostomy was about to be performed when the gall bladder began to bleed Nothing had been done to cause this except the introduction of a dull spoon, as the finger could not reach to the bottom of the gall bladder Bleeding became excessive, and was not controlled even when five yards of iodoform gauze had been packed into the gall bladder The hæmorrhage became alarming 20 c c of horse serum were injected hypodermically without result Then a flask of horse serum was poured into the gall bladder Coagulation immediately occurred and the hæmorrhage ceased The gall bladder was re packed and the bleeding did not recur.

MEDICAL EDUCATION IN CARDIFF.

THE medical school at Cardiff—the only medical school in Wales—is now within sight of completion, and the question of clinical instruction to the students is therefore one of immediate interest The obvious and natural place in which this should be given is King Edward VII 's Hospital, the modern institution of over 200 beds which has lately arisen out of what was the Cardiff Infirmary, and arrangements have accordingly been made with this end in view The *personnel* of the visiting staff of this hospital thus becomes a matter of the highest importance since the future of the Cardiff Medical School will largely depend on the quality of the clinical teaching to be obtained in the wards and out patient rooms of King Edward VII 's Hospital As it happens, owing to the death of Dr Arthur E Taylor, and the resignation, through the age limit, of Dr Herbert R Vachell, both physicians to the hospital, two vacancies are now impending on the honorary staff The board of management, we understand, are alive to the responsibility which thus falls upon them in filling these vacant posts, and they have expressed their intention of recruiting from among men of the highest qualifications, with a zealous regard to fitness irrespective of all other claims put forward by candidates or their supporters It follows from this that the most appropriate candidates would be those who practise as consulting physicians, and who, if possible, have already had experience of teaching We should be the last to suggest that a leading general practitioner is not often able to give clinical instruction as sound and useful to the student as it would be possible to give The point is that time and proven ability to teach should be essential qualifications for appointments in hospitals attached to medical schools It is the medical school which necessitates a specialist staff The election committee at King Edward VII 's Hospital, Cardiff, is commendably small, and its choice is final If its claim to independence and impartiality is just there should be little difficulty in making suitable appointments From now onwards those who are elected to the honorary staff of this institution will have in their charge the efficiency and good name, not only of the hospital, but also of the Cardiff Medical School.

A CRUSADE AGAINST VENEREAL INFECTION IN AUSTRALIA

INCREASING knowledge carries with it increasing responsibility Reticence in regard to the venereal diseases was acquiesced in, if not fostered by, the medical profession when the wide extent of the effects of these diseases was less known and the large proportion of innocent sufferers was unsuspected But the day has gone by when these diseases can be regarded as necessarily evidence of personal immorality, and reticence must with increasing knowledge be replaced by a judicious widespread publicity in order that adequate measures may be prepared It is very interesting in this connexion to read that steps have been taken in Australia in accordance with the wider modern views In *Bedrock* for April Dr James W. Barrett, C M G , describes how, in Victoria a general discussion between pathologists, oculists, and specialists in children's diseases on the one hand, and many members of the general medical profession on the other, as to the extent of distribution of venereal diseases, led to the passing of a resolution at the Australasian Medical Congress in Melbourne in 1908, affirming the wide extent of the infection and urging on the Government the taking of preventive and remedial measures The evidence on which this resolution was based consisted among other things of two sets of 100 necropsies, each made indiscriminately at the Melbourne Hospital on the bodies of persons who had died from varied causes In each set of necropsies 30 per cent showed pathologically syphilitic affections in the arteries and organs Ophthalmologists added their testimony as to the frequent association of certain appearances with a history and other signs of syphilis, and *in this they were supported by analogous* conclusions on the part of those who had worked largely in connexion with diseases of children The resolution of the Congress having been brought before the Victorian Government, the latter, on the advice of their medical officer, Dr Burnett Ham, established an advisory committee of medical practitioners to investigate the subject Investigation was pursued along the following lines For 12 months syphilis was made compulsorily notifiable as to age, sex, and clinical conditions , a specimen of blood for the Wassermann test was submitted in all cases of residence within 12 miles of the Melbourne Post Office, no names, however, being mentioned *Not only obvious cases of syphilis*, but conditions supposed to be indirectly due thereto were reported. By the end of the year out of 5000 cases reported and tested for syphilis 3167 (or 0 5 per cent of the entire population) proved to be syphilitic Again, during four months, at the Victorian Eye and Ear Hospital, every new case of disease of eye, ear, or throat, 550 cases in all, was submitted to the Wassermann test, with the result that of the eye cases 13 per cent , and of the ear and throat cases 15 8 per cent , were found to be syphilitic At the Children's Hospital examination of all who showed signs of syphilis confirmed the position The results of the inquiry, therefore, proved that the distribution of the disease was very wide, that the evidences on which diagnosis was based were valid, and that the resulting damage to the race was enormous. The Women's Hospital added further testimony to the effect that half their operative work was occasioned by gonorrhœa. A summary of the evidence was reported by Dr Ham to the Government, which authorised publication in the press and appointed a permanent advisory committee to deal with the situation The first difficulty in public education was seen to be the moral objection based on the mistaken premise that sufferers from venereal disease are rightly served. Therefore it was shown that while the crafty and cold-blooded offenders were often able to avoid the consequences of their acts, it was the impulsive and simple-minded who more generally suffered; and, moreover, half the sufferers from gonorrhœa, and more than half of those from syphilis, were found to be not in any way morally responsible for their plight. The aid was sought of the National Council of Women, which passed a resolution offering coöperation with the Government in any reasonable steps. The press was also appealed to and consented to publish official and unexpurgated accounts of the steps taken, and to speak out plainly, avoiding euphemisms. The clergy also allowed the medical profession to give a temperate statement of the facts in their churches. The Government now furnished and equipped wards in the Alfred Hospital and the Women's Hospital for the treatment of any persons (other than prostitutes, who were otherwise provided for) suffering from these diseases in any of their contagious forms. They also arranged with the University of Melbourne for a free application of the Wassermann test to 2000 hospital cases annually, and at a low rate for all other cases. Finally, it is proposed to introduce a modified form of a New South Wales statute, which provides that any person sentenced to imprisonment for any cause and found to be suffering from a venereal disease in a contagious form may be detained until he can be released with safety to others. With these operations at work there is reason to hope that the elimination of venereal diseases is within the region of possibility. Dr. Barrett, as a result of his observations during a recent visit to Europe, considers syphilis far more common in Europe than in Australia, and while admitting that, in consequence probably of better treatment and hygiene, the graver manifestations are less common than formerly, holds that "submerged syphilis" is just as frequent and as deadly, since syphilitic nervous disease is not decreasing. He makes the suggestion that the examination by the Wassermann test of every patient admitted to the Brompton Hospital during a sufficient period would probably settle the relation of syphilis to tuberculous infection. Professor E. H. Starling, in a prefatory note to Dr. Barrett's article, urges that since in this country the State has now fully assumed responsibility for the national health, it is right that the public should be made acquainted with the measures taken in another part of our Empire, and asks if there is any reason why similar measures should not be adopted in this country.

THE COMMON HAIRBRUSH.

THE tendency of modern times is to make civilised people much more fastidious than were their ancestors. At one time at a meal the meat was served in a dish from which each diner took with his fingers what he required, and cut it on his own plate with his knife; at an early period the knife used was that which served for many other purposes, and it was never what is now called clean. The practice of feeding from a common dish obtains to-day among the Arabs, most courteous of hosts, if not so exuberant in their attentions as the dinner givers in some savage countries, where it is considered a polite attention for the entertainer to take a toothsome morsel from his own lips and to place it in the mouth of his guest. Customs such as these must have tended to spread disease. We have changed our manners in many respects, but there are still many habits of life in which greater care might be exercised. The risk of infection is materially diminished by taking a reasonable amount of care, and this is true not only of the more serious diseases, such as the infectious fevers, but also of the slighter affections such as ringworm. It is curious that even at the present day very little care is taken to prevent infection of the scalp. Until recently even hairdressers employed the same brush to all customers without making any attempt to disinfect it or even to cleanse it. Now it is true that many hairdressers do attempt to sterilise the brushes and other implements which they employ, but it is still customary with many persons to employ almost any hairbrush which may be available. In the dressing-rooms of clubs common hairbrushes are provided, and few hesitate to employ them. Now it is generally agreed that seborrhœa of the scalp is microbic in origin, and though the resisting power of the individual is an important factor in the production of the disease, infection also plays an active part. So that it cannot be doubted that the use of a hairbrush employed by others carries risk. It is not improbable that the increase of baldness in civilised communities is associated with the greater risks of infection of the scalp which exist.

TRAUMATIC APPENDICITIS.

CASES of appendicitis attributed to injury are rare; about 100 have been recorded. The condition has been discussed by many writers who have given varying estimates of its frequency, ranging from 0·8 to 8 per cent. This difference is not surprising as relations of cause and effect are difficult to establish in medicine. The problem is often highly complex, and even industrious writers are often wanting in the logical aptitude or training necessary for an accurate conception of the word "cause." Some writers accept only cases in which appendicitis appears after direct and violent injury to the abdomen; others include such factors as a hard day's work, horn-blowing, or defæcation. Only one writer, Sprengel, denies the existence of traumatic appendicitis, and holds that the combination with trauma is a mere coincidence. Others hold that trauma merely causes an exacerbation of a latent inflammation. Still others believe that trauma alone may cause appendicitis. All except Sprengel agree that injury may cause appendicitis in persons who previously showed no signs of the disease. In the *Progrès Médical* of Jan. 11th M. G. Daniel has reported the following case. A woman, aged 18 years, was admitted into hospital on August 20th, 1912. On July 11th she was kicked in the right iliac fossa by her husband. She was knocked down, but was able to get up without assistance. For ten minutes she felt severe pain over the whole abdomen. Then the pain gradually disappeared. She did not take to bed, and on the following day made several journeys, and on the day after that resumed work. Previously to the injury she was in good health and had not suffered from any digestive trouble. On the evening of July 18th, having felt nothing abnormal in the interval, she suffered from acute abdominal pain which became worse during the night and compelled her to remain in bed on the following day. The pains were then principally felt in the right iliac fossa. There were obstinate constipation and frequent vomiting. The temperature was 102·2° F. The symptoms increased, and on the 26th the temperature was 104·5°. It remained at this level until August 6th, when the symptoms began to regress, and on the 14th the temperature was normal. However, two days later the same symptoms began again and she was taken to hospital on the 20th. On admission the temperature was 103·5°, the pulse was 120, the facies was altered, and the respiration was rapid. The whole abdomen was painful, but the right iliac fossa was the most tender. On palpation there was marked "muscular defence," which, however, did not prevent a large induration from being felt. Vaginal examination was negative. Traumatic appendicitis was diagnosed. Under medical treatment the temperature fell to normal and the symptoms improved On Sept 2nd an "interval operation" was performed On the anterior surface of the cæcum was a subserous ecchymosis In consequence of adhesions the appendix was discovered with difficulty It was rolled up in spiral fashion and surrounded by peritoneal bands, especially at its extremity, which was adherent to the ileum It was dissected out and amputated with the thermo cautery Recovery was uninterrupted On opening the appendix neither foreign body nor calculus was found, only slight hæmorrhagic blotching was observed At the free extremity the lesions were greatest; there was some pus, the wall was thinned, and the mucous membrane was violaceous M Daniel claims this case as clearly one of traumatic appendicitis in which there were no preceding lesions of the appendix But, he asks, What is to be understood by traumatic appendicitis? He accepts the conclusions of Guinard which are as follows 1 Cases of direct injury of the appendix, comparable to contusion of a segment of intestine, must be excluded from the category of traumatic appendicitis Here the effect is not appendicitis but traumatic perforation, producing peritonitis 2 Cases of appendicitis following an injury in a patient who has had previous attacks or even in one who is predisposed to infection in consequence—for example, of the presence in the appendix of a foreign body or a calculus—must also be excluded 3 Only those cases in which the appendix was sound at the time of the injury and in which direct contusion can be eliminated should be termed traumatic appendicitis Guinard considers that the injury causes the formation of little adhesions around the appendix which kink it, as in the case related above, and thus place it in danger of infection. In some cases the mechanism of a hæmatoma may be invoked, as has been done by Sonneburg Contusion of the appendix may be differentiated from traumatic appendicitis by the fact that in the former the symptoms immediately follow the injury, while in the latter there is an interval

THE TOXICITY OF THE SALICYLATES

IN the *Journal of the American Medical Association* of March 29th Dr Paul J Hanzlik reports the results of an investigation into the toxicity of the salicylates based on an examination of the clinical records of about 400 cases treated at the Lakeside Hospital, Cleveland The method of administration employed in this institution has been such as to facilitate this inquiry, the drug is given in hourly doses until symptoms of intoxication (headache, nausea, vomiting, deafness, tinnitus, &c) make their appearance The total amount given prior to these manifestations constitutes the toxic dose Averages were calculated, not by the usual means, but by arranging the doses given to a group of cases in ascending order, and taking the middle dose of the series as the mean toxic dose for that group of cases In 333 cases the drug was given in the form of the synthetic sodium salt, in 9 cases the natural sodium salt was given, in 9 methyl salicylate, in 7 aspirin (acetylsalicylic acid) and in 6 diplosal (salicylo-salicylic acid) In the case of the synthetic sodium salt the mean toxic dose for adult males was 180 grains, for females 140 grains, of the natural salt, 200 and 135 grains respectively, of the methyl salt, 120 minims alike for male and female, of aspirin, 165 and 120 grains respectively, of diplosal, 100 and 83 grains respectively The difference between the toxic dose for males and for females corresponds approximately with the average difference in body weight The toxic dose of the synthetic salicylate of soda ranged in males from 60 grains (in 16 cases) to 1300 grains (in 1 case, given as a single dose), in females from 20 to 300 grains For most individuals it lay between 100 and 200 grains No relation could be found between age and tolerance for salicylates between the ages of 16 and 75, neither was any racial susceptibility traceable. One very interesting point is brought out by an examination of the relation between the size of the toxic dose and the malady for which the drug was given, it appears from Dr Hanzlik's table that there was no greater tolerance for the synthetic salicylate in cases of rheumatic fever and subacute rheumatism than in other affections, and this seemed to be true of the other salicylates Further, the responsiveness of the case to salicylate treatment had no effect in modifying the magnitude of the toxic dose The figures tabulated bear out general experience in one important respect it was in rheumatic fever that therapeutic success most often followed administration of the toxic dose of salicylate The conclusion in respect to the influence of salicylates in albuminuria, though only provisional, is of interest, it is to the effect that albuminuria in rheumatic fever is to be ascribed to the disease and not to the action of the drug Finally, idiosyncrasy to salicylates is shown not to depend on age, sex, race, or nature of disease, indeed, in a majority of those persons who appeared to exhibit an idiosyncrasy to the drug the toxic dose varied from time to time In one respect this otherwise exhaustive investigation is disappointingly incomplete Dr Hanzlik states that in most cases the salicylate was combined with bicarbonate of soda, but he does not say whether this device had any effect in increasing tolerance to the drug To British investigators this point is one of some importance, and it is to be hoped that Dr. Hanzlik will some day complete his valuable researches by deliberation upon this point also

SMOKING IN THE THEATRE

THE suggestion to permit smoking in the theatre as an inducement to increase the number of its patrons obviously raises some points of hygienic importance It is easy enough, of course, to prove that if the suggestion were carried through the playgoing public would be submitted whether they liked it or not, to an atmosphere of burning pipe, cigar, or cigarette which cannot add to the healthiness of the surroundings Courteous smokers will respect the reasons which induce many people to refrain from the indulgence—and in not a few cases there may be decided medical reasons included—while it is certain that it does no harm to anybody to give up smoking at any time Scientific evidence is hardly needed to show that to some extent the person breathing a smoke tainted atmosphere is liable to the same evils as the person who is smoking, for the experience of a non smoker who has spent an evening in the atmosphere of a smoking concert is often that he sustains a disturbance of health similar to that sometimes complained of by the excessive smoker It is doubtful whether such discomforts arise from nicotine, they are more likely due to imperfect products of combustion, amongst which must be reckoned irritating empyreumatics and the decidedly poisonous gas carbon monoxide It is certain that if the air of a theatre in which a large company of people were smoking were examined it would show a result very far from a standard of purity The only concession that might be made would be to reserve certain parts of the theatre for smokers and to provide a special system of ventilation in those parts which would effectually prevent the smoke from annoying those who do not choose to smoke If this is impracticable, then the prohibition of smoking in theatres seems to us to be reasonable. It will, of course, be urged that smoking is permitted in the theatre of varieties or music hall, and the public appear to appreciate the privilege There are compensations, however, in regard to the theatre in which smoking is not allowed, which a good many people very properly value—namely, the atmosphere is cleaner and clearer; the floors are not bestrewn with tobacco ash, fag ends of cigars and cigarettes, and dead matches; the annoyance caused by the lighting of matches during a darkened scene is happily avoided; and the fittings are free from tobacco reek. These considerations add not a little to the enjoyment of a play.

THE MATERNITY HOSPITALS AND THE INSURANCE ACT.

IT would surely seem time that some combined action was taken by the maternity hospitals in the United Kingdom in reference to the Insurance Act. On these institutions the duty devolves of training both midwives and students, and the fact that the General Medical Council and the English Midwives Board insist—and most wisely so—that both pupil midwives and medical students must present evidence, among other things, that they have had *each* personal charge of 20 cases of labour, makes it essential that nothing should interfere with the hospitals' power of providing such teaching material. Further, in large towns, it is to the maternity hospitals that the difficult cases among the poor (insured or not) will always be sent. But now that the Insurance Act makes the poverty of many women much less, the questions arise, Should the women or their societies be expected to pay the maternities for providing them with skilled nursing and treatment? and, if so, what scale should be adopted, and should it be the same or different for extern and intern cases? These are problems awaiting solution. It would seem that at present different methods are being adopted in different teaching centres, but the establishment of some system applicable to all maternity hospitals alike ought to be possible after consultation with panel doctors, Approved Societies, and the authorities, lay and medical, of the lying-in charities.

FOUR Gresham lectures on Drugs Old and New will be delivered on May 13th, 14th, 15th, and 16th by Dr. F. M. Sandwith, Gresham professor of physic, at the City of London School, Victoria Embankment, London, E.C. The lectures are free to the public, and will begin each evening at 6 o'clock.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.—The festival dinner of this institution was held on April 16th at the Whitehall Rooms, Hotel Métropole, London. The president of the hospital, Lord Strathcona, was in the chair, and he was supported, among others, by H.S.H. Prince Alexander of Teck, Lord Justice Kennedy, the Dean of Canterbury, Sir David and Lady Ferrier, Sir Frederick and Lady Macmillan, and many members of the visiting staff. The toast of the evening, "Success to the National Hospital for the Paralysed and Epileptic," was proposed by the chairman, and was acknowledged by Sir Frederick Macmillan, chairman of the board of management, who pointed to the progress which had taken place in the past 11 years, and justified the policy of improving the equipment rather than increasing the number of beds. The health of the medical, surgical, and nursing staffs was proposed in an eloquent and discerning speech by Dr. Wace, Dean of Canterbury. Sir Victor Horsley, in reply, paid a great tribute to Lord Strathcona's benefactions to hospitals and to medical science. Modern advances in methods of diagnosis and the obscure nature of the diseases treated there produced a special strain on the finances of the National Hospital; but no medical staff ever had more support from its board than theirs had done during the past 11 years. The secretary, Mr. Godfrey Hamilton, then announced the sums collected that evening, which amounted to over £2300, and included £1000 from Lord Strathcona. Prince Alexander of Teck then proposed the health of the chairman, whom he described as a veteran in Imperial work and in the cause of charity, and Lord Strathcona briefly responded.

FREUD'S THEORY OF DREAMS.[1]

BY WILLIAM BROWN, M.A. OXON., D.SC. LOND.,
HEAD OF THE PSYCHOLOGICAL DEPARTMENT, KING'S COLLEGE, UNIVERSITY OF LONDON.

(Concluded from page 1118.)

III.

BEFORE setting out Professor Freud's elaborate "Psychology of Dream Processes" as given in the concluding chapter of the "Traumdeutung," and using it as the basis of criticism of his theory from the point of view of modern psychology, it will be well for us to consider two rather obvious objections which, if valid, would stultify the theory from the very outset. In the first place it may be contended that the memory for dreams, which is our only source of knowledge of them, is notoriously fallacious. Not only is it fragmentary, showing complete forgetfulness of whole stretches of the dream-experience, but it falsifies those parts that are retained. If a person is asked to describe his dream at different periods after the actual dream-experience, the various accounts which he gives are found to be not only different, but even in many respects inconsistent with one another. He also feels very uncertain about the precise nature of the events described. Morton Prince regards this difficulty in remembering as merely a special instance of "amnesia for dissociated states of consciousness," and a proof that dream-experiences are nothing but such dissociated states brought about by the condition of sleep. But such an explanation can hardly be valid, since Freud and others have found that if they wake up from a dream in the course of the night, interpret it by their method, and then fall to sleep again, they are the next morning often unable to remember either the dream or its interpretation. Now the interpretation is not a "dissociated state," so that Morton Prince's explanation here falls to the ground. The true explanation in Freud's view is that the forgetting is due to the action of the "censor," which in such cases as these suppresses the memory, not only of the dream, but also of its interpretation. It is merely the continuation in the waking state of that process of distortion and secondary elaboration which we have seen to result from the activity of the censor throughout the dream-experience. And since the laws of these processes are known, the amnesia and falsification present no insuperable difficulty to analysis and interpretation. The fragments of the dream that remain in the memory are as a rule sufficient to give the clue to the underlying dream-thoughts when submitted to the technique of psycho-analysis. The feeling of uncertainty which the dreamer often has about the memory of his dream is also to be attributed to the action of the censor, and only by rigorously ignoring this feeling and treating all his memories as on the same level of reliability can he hope to overcome the resistance sufficiently to penetrate to the dream-meaning. Freud has often found, in the case of his hysterical patients, that a dream which the patient has apparently quite forgotten may suddenly rise to memory in the course of a psycho-analysis where a resistance connected with the patient's symptoms has at last been overcome, showing most convincingly that the amnesia for the dream must have been due to a similar, if not the same, resistance.

The second objection is aimed at the reliability of the method of psycho-analysis. It is contended that a chain of free associations starting from any particular portion of the dream may end anywhere, and that then, when another portion is submitted to the same treatment, the associations are no longer completely "free," since they are to some extent, however slightly, determined and constrained by the result of the previous association series. Consequently it is no wonder that in the final result the various chains of association are found all to converge to one and the same system of dream-thoughts.

To this we may reply, firstly, that the interconnexions discovered by this method between the manifest and the latent contents are far too complex and far too full of surprises, cross-connexions, and remarkable coincidences to be regarded as merely the products of the method itself. But, secondly, the method is not with complete accuracy called one of *free* association. All associations without exception are *dominated by some interest or purpose*, and when the subject's voluntary and conscious purposes are allowed to fall into abeyance in the non-critical attitude adopted in psycho analysis, unconscious purposes take their place and guide the course of the ideas It is because of this fact that psycho analysis is able to give us an insight into the nature and structure of the unconscious

---

[1] A paper read before the Listerian Society at King's College Hospital on Jan. 21st, 1913.

The other great method that has been found successful in the same task is that of hypnotism, but Freud's objections to hypnotism are that it is not sufficiently universal—only a small proportion of patients are amenable to hypnotism—and also that, although it overcomes some resistance and so widens the field of mental life open to observation, it accentuates the resistances at the border of this field and thus makes complete analysis of the unconscious in any direction impossible As is well known, Professor Jung, of Zürich, has improved on Freud's method by employing lists of words, previously selected and arranged, and calling them out to the subject The subject is told to reply to each as quickly as possible with the first word that comes into his mind The times taken in replying—the association times as they are called—are measured in fifths of a second by means of a stop-watch, and are as valuable as the associations themselves in revealing the workings of the unconscious Those words which strike on an unconscious emotional "complex" or system of ideas give prolonged association times—in hysterical patients as long as six or seven seconds instead of the normal one and a fifth seconds Sometimes the subject is quite unable to give any associated word Such failure or difficulty in responding reveal the resistances to which the ideas in the unconscious are exposed The ideas themselves can only rise to consciousness when these resistances have been completely overcome A combination of the original more natural method and that of Jung is probably the best for the dream analysis of normal persons Certain refinements on Jung's technique are possible, which it is unnecessary for us to consider here

Freud has attempted to give a theoretical explanation of dream processes, which, he thinks, is identical with showing their relations to the better known processes of waking consciousness Considering the structure of the mind on the model of a reflex apparatus receiving sense impressions at the one "end" and controlling the muscular activity of the body at the other, he postulates a number of psychical systems or "*instances*" arranged in definite order—occupying relatively fixed "psychical localities'—between these two limits The excitation corresponding to mental activity passes, in ordinary cases from the sensory to the motor end—i e, in the progredient direction Immediately adjacent to the motor end is the fore conscious, to which the direct control of motility is limited Behind this is the unconscious, separated from the fore conscious by the censor "as by a screen", behind this, again, a series of memory systems whose function it is to retain the after-effects of perception in different forms of interconnexion, the memory system immediately adjacent to the sensory end of the whole apparatus representing memory traces connected merely by associations of contiguity others in front of this corresponding to the same traces related according to similarity, contrast, and other forms of association or logical connexion Freud compares the apparatus to an optical instrument, such as a telescope or microscope, whose lenses would correspond to the subsidiary systems or "instances" above mentioned, and he takes care to emphasise the metaphorical nature of his description The systems have no more real physical positions one behind the other, than have the virtual images produced in certain circumstances by refraction of light through lenses, but their activities are related to one another according to a certain order, and the spatial metaphor is used simply to express this order Now, whereas the normal processes of waking consciousness correspond, as above mentioned to a progredient direction of the flow of excitation through the apparatus of the mind many peculiarities of dream consciousness are explained on the assumption that the course of the excitation is in part "regredient" Owing to the resistance of the censor and the lowered excitability of the fore conscious, the excitation process corresponding to the sleepless working of the unconscious is reflected backwards, and reaches eventually the sensory end of the apparatus, traversing the various memory systems in doing so As a result of this process of "regression" the dream not only acquires sensory or hallucinatory vividness, but its thought relations become replaced by the most superficial forms of association—namely, those of contiguity and similarity In this way the censor is not so much overcome as circumvented, the dream reaching consciousness at the sensory instead of at the motor end In ordinary remembering and waking reverie a similar regression takes place, but it is incomplete and does not pass beyond the memory systems What aids the dream process to actually reach the terminal perceptual system is partly the cessation of the progredient stream of excitation continually passing from the sensory to the motor side of the apparatus of the mind during waking life, but mainly the processes of *displacement* and *condensation* which we have already seen to be characteristic of dream experience, and are peculiarities limited to the working of the unconscious The psychical intensities of unconscious ideas are displaceable so that they can be accumulated upon one single idea or a relatively small number of ideas which thus acquire a sufficient intensity to attract the attention and so become conscious But even these do not become conscious in their own form, but *attract*, or are attracted by, corresponding ideas from the fore conscious, and endow [illegible] with their psychical inten[illegible] hallucinatory vividness [illegible] "selective attraction" to explain the hallucinations of mental disease (other than those resulting from organic lesions), which he thinks are also due to the activity of the unconscious

Speaking in less metaphorical language, the unconscious and the fore conscious correspond to two fundamentally different modes of activity of the mind, of which the former is the more primitive, and it is because the unconscious can only wish and is incapable of any other form of mental activity that dreams have as their innermost meanings wish fulfilments, and wish fulfilments only Freud's attempt to prove this thesis theoretically cannot be regarded as successful, and its lack of plausibility is my excuse for not quoting it in this paper It may as a fact be true, but that is another matter In my own view, fears, anxieties, and antipathies are equally primitive and equally prone to appear as the inner meaning of dreams Nor can I verify from my own experience the view of some of Freud's followers that the wishes forming the dream thoughts or latent contents of dreams are always of a sexual nature Freud himself does not go so far as this, although he is inclined to think it probable It should not be forgotten that he approached the problem of dreams from the side of abnormal psychology Having been led by his studies on hysteria to a new theory of the nature and workings of the unconscious in this class of mental disorder, he then found, or thought he found that the same theory could be made to include the dreams of normal persons, the dreams corresponding to the symptoms of the hysteric in being disguised fulfilments of repressed and therefore unconscious wishes or tendencies And since he found that these wishes in the case of the hysteric were invariably of a sexual nature, dating from early childhood, he was tempted to the view that the wishes fulfilled in dreams are always infantile sexual wishes, and his disciples contend that the results of psycho analysis applied to thousands of dreams bear out this theory All that one can say in reply to this is that these investigators seem somewhat overpowered by the feeling of partisanship and have probably allowed their findings in many cases to be influenced by their expectations Unbiassed psychologists, who have been trained to observe impartially the workings of their minds, are unable to support this extreme view On the other hand, the critics of the Freudian school show an even more pronounced and irrationa[illegible] come fro[illegible] adopted [illegible] Freud's sexual t[illegible] understanding [illegible] in the wide sens[illegible] a much more important part in the mental life of the individual and of the race than is generally recognised, and Freud has made a most valuable contribution to psychology in emphasising its significance and supporting his theory by such a wealth of concrete facts

To return to our problem of dreams Every dream fulfils at least *two* wishes, one originating in the unconscious, the other in the fore-conscious. The fore-conscious wish is the wish to sleep, so that the dream is a compromise between this wish-fulfilment and those of the unconscious. Similarly in the case of hysteria Freud has observed that not only is an unconscious wish fulfilled in a disguised form by the hysterical symptoms, but that a wish originating in the fore-conscious, and generally of the nature of a self-punishment, is also fulfilled by the same symptoms; in fact, the symptoms are so chosen that they conform to both wish-fulfilments and constitute a compromise just as the dream does. Anxiety dreams and anxiety neuroses represent a breaking-down of this compromise and indicate the real purpose of the compromise—viz., to prevent the arousal of the painful feeling known as anxiety. Further discussion of this question belongs to pathological psychology and does not fall within the scope of our present inquiry.

The essence of Freud's dream-hypothesis from the purely theoretical point of view is his distinction of two kinds of mental mechanism, a primary and a secondary. It is the laws of the secondary mechanism that are given in ordinary text-books of psychology. Those of the primary mechanism are in some respects very different. They include the processes of condensation, transference, "draining-off" of energy or intensity from one idea to another, and finally regression, as we have described it earlier in this paper. Freud claims to find the same processes active in cases of hysteria, and seems to regard his view of each of these two classes of facts as confirmatory of the other. All these processes, although psychical in nature, may occur independently of consciousness. Consciousness, in Freud's view, is merely a kind of sense-organ which does or does not perceive these psychical processes and products according to the distribution at the moment of the mental energy which we call attention. This account of consciousness will hardly satisfy psychologists, but many of them will be ready to admit the real existence of the unconscious in the Freudian sense, as well as of the fore-conscious. Many of Freud's difficulties are difficulties of terms rather than of facts. We may accept his facts and value them as new discoveries, while rejecting some of his terms and descriptions as misleading. The term "censor" corresponds to a verifiable fact, but the figurative use which Freud makes of it is not without danger. The censor is not an entity existing by itself and in its own right, nor is it really intelligible apart from all reference to consciousness, as Freud would have it to be; and when he speaks of a second censor between the fore-conscious and consciousness, one feels a still greater difficulty in knowing exactly what meaning to attach to the word. Yet the term is useful as emphasising the fact of repression, and for descriptive purposes is well-nigh indispensable.

One is continually tempted, while reading Freud, to correlate his distinction of a primary and secondary mental mechanism with the physiological distinction of the lower and upper motor circuits in the nervous system, especially as he limits the function of inhibition and the power of facing painful experience, and not merely turning away from it, to the secondary mechanism. But this would be an error, since the distinction corresponds to one within the upper motor circuit—indeed, within the physiological mechanism of the cerebrum itself. The primary process is a process of wish-phantasy which one can easily observe in the mental life of young children. It represents the stage of mental evolution when ideation, as distinct from merely perceptual experience, first became possible, and Freud's work has served to throw a great deal of light upon the nature and mode of working of this obscure and unduly neglected phase of mental life. No psychologist, unless he is hide-bound in tradition and prejudice, can fail to be attracted by the prospect of further psychological advance opened up by this work. Unless Freud's critics are ready to put themselves to the trouble of mastering his technique and giving the method of psycho-analysis an honest trial they do not deserve a hearing, and by their irrational attitude of blind opposition they bring into discredit psychology itself.

ROYAL INSTITUTION.—On Tuesday next (April 29th) at 3 o'clock Professor William Stirling begins a course of three lectures at the Royal Institution on "Recent Physiological Inquiries." Owing to the illness of Professor Bateson, his course of lectures on "The Heredity of Sex and some Cognate Problems" has been postponed.

THE FINAL REPORT OF THE ROYAL COMMISSION ON UNIVERSITY EDUCATION IN LONDON.

I.

IN the following short series of articles we propose to abstract the final report of the Commissioners on University Education in London, which was noticed on its appearance in a leading article in THE LANCET last week. But, although it is our intention to give the gist of the Commissioners' findings and recommendations, the report is so exhaustive and so closely written that our readers must understand that reference to the document itself is indispensable. The whole report is deeply interesting, and should be read by all who are interested in education and in the future of the University of London, while there are innumerable references in it, both direct and indirect, to the medical aspects of the problem.

The Royal Commission on University Education in London was appointed early in 1909

> to inquire into the working of the present organisation of the University of London and into other facilities for advanced education (general, professional, and technical) existing in London for persons of either sex above secondary school age; to consider what provision should exist in the metropolis for university teaching and research; to make recommendations as to the relations which should in consequence subsist between the University of London, its incorporated Colleges, the Imperial College of Science and Technology, the other schools of the University, and the various public institutions and bodies concerned; and further, to recommend as to any changes of constitution and organisation which appear desirable, regard being had to the facilities for education and research which the metropolis should afford for specialist and advanced students in connexion with the provision existing in other parts of the United Kingdom and of His Majesty's Dominions beyond the Seas.

With their final report the Commissioners issue as an appendix of 300 pages the minutes of evidence given before them from February to December, 1912.[1] It will be remembered that on four previous occasions they issued minutes of evidence, and that in December, 1911, they made an interim report upon the question of a University site. Reference to these documents have been made from time to time in THE LANCET. The late Sir William Allchin's unfinished "Account of the Reconstruction of the University of London," undertaken by request of the Commission and very warmly praised in the final report, has also been noticed in our columns.[2]

The final report is preceded by a valuable analysis of its contents which occupies 24 closely printed pages, while the remainder of the Blue-book consists of 218 pages of foolscap.

Part I. opens with a concise statement of what the Commissioners conceived to be the duties imposed upon them by the terms of reference quoted above. In their opinion they had to ascertain: (I.) How the present organisation of the University of London works, and what provision the University of London makes at present for University education—general, professional, and technical. Upon this they were to determine by consideration and inquiry. (II.) What provision should exist in the metropolis for university teaching and research. In deciding this question they were to keep in mind, among other things, that London is the capital of the Empire, and that it may be right to provide there special facilities for education and research for specialist and advanced students in connexion with the provision existing in other parts of the Empire. (III.) When the facts referred to in I. had been ascertained, and the questions to be considered in II. had been determined, they were to make recommendations with regard to the following matters:—

> What, if any, changes in the constitution and organisation of the University are necessary—
> (*a*) To ensure that the University will work harmoniously and well.
> (*b*) To enable the University to make, manage, and develop the provision for university education and research which in our opinion is necessary or desirable.

The two fundamental questions of the reference appeared to the Commissioners to be:—

> How does the present organisation of the University of London work? And what provision ought to be made in London for university teaching and research?

---

[1] Cd. 6718. *Price 2s. 5d.*

[2] THE LANCET, vol. i., 1911, p. 1363.

Their task they therefore shortly state as follows :—

To examine the existing provision for university education in London in the light of what we think ought to exist, and to make practical recommendations towards the realisation of the ideal.

With regard to the working of the present organisation of the University the Commissioners state :—

[illegible] recognised for University purposes.

In addition to the difficulties which arise from these two main [illegible] nt machinery of government [illegible] ad to difficulty and delay in [illegible] ct of organisation, but it is [illegible] arise from the second main ground we have mentioned might have been overcome, or at least greatly reduced, if the University had been in possession of substantial funds, and had wisely administered them with these ends in view.

A historical retrospect follows, in which it is shown how the original desire and intention to found a University for London upon the lines of Oxford and Cambridge Universities had to be diverted into the establishment of an [illegible] ked [illegible] An [illegible] the University of London from its foundation to the present time. The Selborne and Gresham Commissions, appointed in 1888 and 1891 respectively, each came to the conclusion that the problem was how to coördinate the recognised teaching institutions of London under a central university. The petition of the Royal Colleges of Physicians of London and Surgeons of England to the Privy Council for a charter was referred to the Selborne Commission and rejected by them. The reason for this petition was the small number of university degrees in medicine obtained in proportion to the number of students and the opportunities for clinical teaching in London. The report of the Gresham Commission was followed by a period of controversy. Four and a half years later the Act of 1898 was passed, containing in a schedule the terms of the compromise arrived at.

The Gresham Commission recommended the Administrative County of London as the university area.

[illegible]

Dealing with the present relations of the internal and external sides of the University the report before us lays it down that the defects in the present organisation of the University, arising from the relations of the internal and external sides, are largely due to departures from the recommendations of the Gresham Commission, and originate in the provisions of the schedule to the Act of 1898. These provisions, as worked out in the Statutes, hamper, without restricting the executive powers of the Senate, by obliging it to invite and receive a report from one or both of two Standing Committees (i.e., the Academic Council and the Council for External Students) before making any decision affecting internal or external students. The following extracts are from the analysis of the report :—

The Academic Council and the Council for External Students having advisory powers only, and the executive authority being the Senate, neither council can get anything done without the consent of the other, unless it obtains the support of members of the Senate independent of both. The result is that questions on which the two councils are most divided are decided in the Senate by the votes of those who have been least able to consider the merits of the case. The machinery of government has [illegible] prevent duplication of institutions—e g., schools of engineering and medicine. Representation of the University on the governing body of [illegible]

Among other defects which the Commissioners find to be connected with the machinery of government of the University is the limited power given to the faculties by the statute. The Faculty of Medicine in particular, the report says, has become too large for effective work, even within the limited sphere assigned to it.

Part II. of the report forms a masterly essay on the aim and scope of modern university education. Its theme is the essentials of a university in a great centre of population. The nature of the provision required in London for university education and research is first discussed, as a necessary preliminary to constructive proposals. We only quote briefly again from the analysis :

[illegible] university [illegible] under full [illegible]

Still dealing with general principles, the Commissioners touch on the subjects of university education for evening students, technological instruction, and working men's classes. Proceeding to the question of degrees and examinations the report contains matter of fundamental importance.

The granting of degrees is one of the chief characteristics of all universities, although it is not the real end of its existence. ...... The [illegible] or [illegible] sity [illegible] it [illegible] been [illegible] a [illegible] are also distinctions.

The examination test, which is the main test in English universities, is discussed from various points of view. External examinations associated with a wide or detailed syllabus of subjects are condemned as tending to uneducational methods of work. The Commissioners object to the whole system of external examination; they say it is based on want of faith in the teachers.

> The present internal examinations are practically external owing to the number of institutions involved and the demands of the common syllabus. Degrees should not be awarded upon examination alone, but should, subject to proper safeguards, be practically the certificates [illegible] of the student's work. [illegible] of a lower standard or [illegible] the standard is equal to its own, until there is general understanding of the true meaning of a university education. But this recognition must not hamper the development of the teaching over which the university has complete control.

The report then proceeds to lay down the conditions necessary for the realisation of the foregoing ends. These, very briefly stated, are as follows: (1) A previous sound general education, giving the power of accurate expression and orderly thought; (2) homogeneity of university classes; (3) a university quarter where the constituent colleges and university departments are grouped together; (4) university hostels and societies, extending the influence of the university over its students; (5) a university professoriate, its own teachers appointed, paid, pensioned, and dismissed by the university; (6) professorial control of teaching and examination; and (7) complete financial control by the University of all the institutions within it.

The following extract from the analysis shows the scheme of government of the University proposed by the Commissioners:—

> The supreme power of the University should be vested in a widely representative Court. The argument that a large and heterogeneous body would have no power is due to confusion of thought between legislative and executive functions. The Court would have final control over the statutes, the admission of institutions as constituent colleges, and the recognition of others as schools of the University.
>
> The Senate should be so constituted as to be able to work out a care- [illegible] intenance and development of univer- [illegible] of its members should be nominated [illegible] other bodies, nor should it consist as to any large part of teachers. Sudden reversals of policy would be guarded against by the legislative control vested in the court, and by its power of bringing public opinion to bear upon University policy.
>
> The Academic Council should be a body of University teachers to which the Senate might delegate some executive functions, and so con- [illegible] s to ensure that the Senate [illegible] niversity professoriate upon [illegible] ersity as a whole.
>
> [illegible] should be provided for the [illegible] e statutes should be simple [illegible] to be settled by regulations [illegible]
>
> [illegible] institutions the principles [illegible] s of the professorial type everywhere else would establish a standard to which institutions for the moment excluded from the University would ultimately be raised. For some institutions meantime a looser form of connexion must be provided and opportunity for graduation offered to the external student.

They sum up by adding that any reconstruction less fundamental than that proposed would be useless.

(To be continued.)

A COLLIERY GARDEN VILLAGE.—The first colliery garden village in South Wales is being formed in Gilfach Goch, a district which, though not actually in the Rhondda valleys, is almost adjoining and very closely associated with that locality. About 70 acres of land have been acquired upon which it is proposed to erect 1000 houses, each of which will have a garden containing some 300 superficial feet. Every house is to have a water-supply, and a hot-water supply will be in each house provided with a bath. The houses are to cost from £200 to £250 each, and will be erected in blocks. The estimated total cost of the undertaking is about £116,000, two-thirds of which will be borrowed from the Public Works Loan Commissioners. It is hoped that between £4000 and £5000 will be taken up in shares by prospective tenants, and £35.000 will be raised by loan stock. The collieries in the vicinity of the village are turning out 200,000 tons of coal yearly, and it is anticipated that with the sinking of other pits this amount may be multiplied four or five times over.

Public Health.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

St. Austell Rural District.—A good deal of public attention has been drawn to the sanitary condition of villages in Cornwall in recent years, and Dr. A. T. Nankivell's report on the district of St. Austell shows that many parts of it require more attention than they have hitherto received in such matters as water-supply, public scavenging, diminution of overcrowding, and improvement in the condition of working-class dwellings. The population of St. Austell is now estimated at over 33,000, and the conspicuous diminution in the number of inhabitants which set in with the decline of tin mining in 1880 has now been checked in consequence of the rise in prosperity of the china clay industry. The latter has led to a demand for house accommodation which is not met by local supply. The lack of houses tends to restrict the progress of the chief local trade while making it increasingly difficult for any sufficient action to be taken by the local authorities in the case of houses which ought to be closed as unfit for human habitation. The difficulties are increased by the immigration of casuals and tramps, of whom some 1300 pass through the workhouse in the year. Dr. Nankivell states that there is already a house famine and nowhere to put tenants who would be displaced by closing orders, and with a view to determining the places in which working-class dwellings are most needed he has made a special survey which should facilitate the task of the district council if it decides to use the Housing Acts to provide working-class houses in suitable situations. It appears from the report that building schemes could be undertaken with great advantage to the district, and probably with little pecuniary loss to the council. Shortage of working-class houses, and dwellings which are structurally unfit for human habitation, are met with conspicuously in the picturesque little town of Fowey, which also suffers from a deficient water-supply, incomplete sewerage, and unsatisfactory scavenging. Fowey is now to be constituted a borough, and so will be separated from the rest of the district, and in future have its own town council and sanitary officers. When it is considered that the population of the place is barely 2300, and that a penny rate produces only £43, it is doubtful whether the privilege of incorporation, however satisfactory on political or sentimental grounds, will work for better sanitary government. St. Austell district, like so many others in Cornwall, has no isolation hospital, and in this and in many other matters it is to be hoped that the local authority will give attention to the recommendations in this report, which obviously represents a great amount of labour. Dr. Nankivell must, however, allow us to quarrel with one sentence in it: "It has been possible to root out leprosy from this and other countries, and it is equally possible to banish tuberculosis." It may be pathologically correct to compare the leper and the consumptive, but in other respects we think the analogy is to be avoided.

Borough of Barnstaple.—Dr. Herbert C. Jonas's report on this old Devonshire town has several points of interest. Antiquity, which is often pleaded as an excuse for inaction in sanitary matters, hardly condones the dumping of town refuse on the outskirts of the borough in a place where it causes serious annoyance to the inhabitants and is constantly rooted over by pigs. In this, and in the provision of covered ashbins in place of filthy ashboxes in the town, there is room for considerable improvement. An inspection of the water-supply early last year led to the discovery of several dead ends to water mains which were provided with ball hydrants, which gave rise to danger of pollution of the supply by insuction, and it is satisfactory to read that these are being replaced by efficient valves. The River Taw is seriously polluted by sewage, the whole of the Barnstaple sewage being discharged untreated into the tidal portion of the stream. It is suggested that the present temporary isolation hospital should be enlarged, and that neighbouring districts should then share in its use. No hospital accommodation is available for small-pox cases, and Dr. Jonas points out that the population now growing up is largely unprotected by vaccination. In the last three and a half years practically 75 per cent. of the children born are unvaccinated. Great improvement is reported in the condition of the districts with worst housing. Out of 216 dwellings inspected for the purposes of Section 17 of the Housing and Town Planning Act as many as 182 were considered to be in a state dangerous or injurious to health; in 112 of these the defects were remedied without the making of a closing order; in 21 the closing order was made, and in 8 the houses were demolished. Looking to the size of the town and to the conditions described by Dr. Jonas this seems to indicate very satisfactory progress, especially if the town council accompany it by the provision of suitable new working-class accommodation.

Borough of Reigate.—In a preface to his annual report Dr. Arthur E. Porter observes that, "the modern tendency of public health administration appears to be to impose large administrative duties upon county councils, while leaving much of the spadework to be carried out by the constituent authorities." He considers it arguable whether this is a desirable arrangement in a county like Surrey, where the standard of public health administration is relatively high. In Reigate much useless clerical work is entailed, while the reciprocal benefit received is quite negligible. Dr. Porter goes on to criticise the Milk and Dairies Bill from this point of view, pointing out that in Surrey reference to the county headquarters is singularly inconvenient for the important districts situated in its eastern half. A hybrid arrangement whereby administrative and executive duties are shared by the larger and smaller authorities in his view cannot fail to be accompanied by overlapping, by regrettable delays, and unnecessary clerical and other work. Most of the houses in the district are supplied by the East Surrey Water Company, the population of whose statutory area now amounts to something like 90,000 persons. The supply, estimated at 25 to 30 gallons per head per diem in Reigate, is derived from deep wells bored about 125 feet into the chalk at Purley and Kenley, where it is softened to 4° Clark or thereabouts. So long as it maintains its high degree of purity it must be placed in the front rank of public water-supplies, but Dr. Porter points out that the chalk which forms the gathering ground is yearly becoming more and more built over, and that while the larger centres are drained to sewers, cesspools are attached to the more scattered groups of dwellings. He considers that the risk that at some future date fissures from which the company's wells derive their water may become polluted by domestic drainage should be guarded against. This is probably more necessary now that the company has obtained Parliamentary sanction to erect additional pumping machinery at their Purley station. In regard to "holiday children" from London Dr. Porter states that stringent measures have been adopted for some years to inspect the houses to which the children are sent, and that every year various societies in London are asked whether they propose to send children to the borough, and if so to furnish a list of the proposed lodgings. It has been found that since this system was adopted the number of holiday children that come to Reigate has been steadily reduced year by year.

REPORTS OF SCHOOL MEDICAL OFFICERS.

Durham County Council.—The work of this education district extends over 622,000 acres, with a population of 707,000 (estimated middle of 1910). There were 138,303 children on the roll attending at 397 schools with 694 departments. To do this work Dr. T. Eustace Hill, the school medical officer, has the help of eight assistants, three of whom are women, and of three school nurses. During 1911, 26,885 children were inspected, 25,302 being routine and 1583 special cases. The tenor of the reports from the different examinations is satisfactory. The percentage of girls with verminous heads was reduced from 48·7 per cent. to 37·4 per cent. and of boys from 1·2 per cent. to 0·69 per cent. Legal proceedings were sanctioned by the education committee against parents whose children were persistently verminous. In only 8 cases out of 30 were prosecutions instituted, 3 were withdrawn, 1 was dismissed on technical grounds, the parent getting a severe reprimand from the chairman of the bench, and in 4 cases convictions were obtained and fines imposed varying from 5*s.* to 20*s.*, plus costs. Scabies was unfortunately very prevalent during the year. Cases with ringworm of the head are allowed to attend school if wearing a washable linen cap. The medical officer calls special attention to the need for the provision of facilities for treatment of this ailment. And attention is also called to the need for reasonable encouragement to teachers to obtain a practical knowledge of hygiene, and further to the need for the provision of open-air classes or schools. Among special reports is one by Miss Cooper Hodgson, health visitor for the central district, who notes that chronic absentees, presumably away from school "to get fresh air," are usually found "hanging about in the house, untidy, depressed-looking little drudges nursing heavy babies, scrubbing floors, or helping with the family washing, or perhaps bread-baking." Dealing with 34 verminous families Miss Hodgson says "in only four cases can the parents be regarded as normal," and enumerates the "parental defects" in the 30. But the classification is too sweeping and too much a matter of individual opinion to be of scientific value. Its publication gives an impression of exactitude probably not deserved. A medical officer has been appointed especially to do refraction work, and has dealt with 366 cases from Sept. 25th, 1911, to Dec. 15th.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 96 English and Welsh towns with populations exceeding 50,000 persons at the last Census, and whose aggregate population at the middle of this year is estimated at 17,852,766 persons, 8960 births and 5420 deaths were registered during the week ended Saturday, April 19th. The annual rate of mortality in these towns, which had been 16·9, 15·6, and 15·2 per 1000 in the three preceding weeks, rose to 15·8 per 1000 in the week under notice. During the 13 weeks of last quarter the mean annual death-rate in these towns averaged 16·9 per 1000, against a corresponding rate of 17·5 in London. The death-rates last week in the several towns ranged from 4·6 in Ealing, 6·1 in Enfield, 6·6 in Ilford, 7·2 in Leyton, and 7·5 in Bournemouth, to 21·7 in Hastings, 21·8 in Stoke-on-Trent and in Carlisle, 21·9 in Stockton-on-Tees, 22 3 in Dewsbury, and 24·0 in Wolverhampton.

The 5420 deaths from all causes in the 96 towns were 225 in excess of the number in the previous week, and included 412 which were referred to the principal epidemic diseases, against numbers steadily declining from 464 to 394 in the five preceding weeks. Of these 412 deaths, 203 resulted from measles, 74 from whooping-cough, 65 from infantile diarrhœal diseases, 41 from diphtheria, 17 from scarlet fever, and 12 from enteric fever, but *not one from small-pox.* The mean annual death-rate from these diseases last week was equal to 1·2 per 1000, and coincided with that recorded in each of the three preceding weeks. The deaths attributed to measles, which had been 208, 215, and 213 in the three preceding weeks, fell to 203 last week, and caused the highest annual death-rates of 1·9 in Willesden, 2·3 in Wigan, 2·6 in Bolton, 2·9 in Southend-on-Sea, 3·1 in St. Helens, 3·3 in Wolverhampton, 3·8 in West Bromwich, *and 6·2 in Gloucester. The deaths referred to whooping-cough,* which had steadily fallen from 83 to 50 in the five preceding weeks, rose to 74 last week, and included 26 in London and 3 each in Southend-on-Sea, in Birmingham, in Manchester, in Leeds, and in Merthyr Tydfil. The fatal cases of diarrhœa and enteritis (among infants under 2 years of age), which had been 71, 53, and 63 in the three preceding weeks, were 65 last week; 18 deaths occurred in London and 3 each in Stoke-on-Trent, in Wolverhampton, and in Middlesbrough. The deaths attributed to diphtheria, which had been 37, 35, and 36 in the three preceding weeks, rose to 41 last week, of which number 11 were registered in London and 3 each in Bradford, in Leeds, and in Stockton-on-Tees. The deaths referred to scarlet fever, which had been 19, 23, and 19 in the three preceding weeks, were 17 last week, and included 5 in Birmingham, 3 in London, and 2 in St. Helens. The fatal cases of enteric fever numbered 12 last week, against 8, 16, and 13 in the three preceding weeks.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and the *London Fever Hospitals,* [illegible] 2112 to 1357 in the 16 pre- [illegible] to 1334 on Saturday last; [illegible] during the week, against 168, 167, and 148 in the three preceding weeks. These hospitals also contained on Saturday last 851 cases of diphtheria, 754 of measles, 260 of whooping-cough, and 38 of enteric fever, but not one of small-pox. The 1424 deaths from all causes in London were 136 in excess of the number in the previous week, and were equal to an annual death-rate of 16·4 per 1000. The deaths referred to diseases of the respiratory system, which had steadily declined from 453 to 285 in the seven preceding weeks, rose to 329 last week, and were 84 above the number recorded in the corresponding week of last year. The deaths attributed to influenza numbered 28, against 45 in each of the two preceding weeks.

Of the 5420 deaths from all causes in the 96 towns, 171 resulted from different forms of violence, and 389 were the subject of coroners' inquests. The causes of 50, or 0·9 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in London and in its 14 suburban districts, in Leeds, Bristol, Hull, Nottingham, Portsmouth, Salford, and in 55 other smaller towns. Of the 50 uncertified causes of death, 9 were registered in Birmingham, 7 in Liverpool, 4 in Stoke-on-Trent, 4 in Warrington, 3 in Bootle, 3 in St. Helens, and 3 in Sheffield.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland, with an aggregate population estimated at 1,199,180 persons at the middle of this year, 661 births and 481 deaths were registered during the week ended Saturday, April 19th. The annual rate of mortality in these towns, which had been 23·8, 23·3, and 22·5 per 1000 in the three preceding weeks, further declined to 20·9 per 1000 in the week under notice. During the 13 weeks of last quarter the mean annual death-rate in these Irish towns averaged 22·2 per 1000; in the 96 large English towns the corresponding rate did not exceed 16·9, while in the 16 Scotch towns it was equal to 19·1 per 1000. The annual death-rate last week was equal to 24·1 in Dublin (against 16·4 in London and 17·3 in Glasgow), 16·9 in Belfast, 22·4 in Cork, 12·7 in Londonderry, 29·8 in Limerick, and 11·4 in Waterford, while in the remaining 21 smaller towns the mean death-rate was 23·1 per 1000.

The 481 deaths from all causes in the 27 Irish towns were 36 fewer than the number in the preceding week, and included 42 which were referred to the principal epidemic diseases, against 39 and 37 in the two preceding weeks. Of these 42 deaths, 18 resulted from measles, 10 from infantile diarrhœal diseases, 6 from whooping-cough, 5 from diphtheria, and 3 from scarlet fever, but not one from enteric fever or from small-pox. These 42 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·9, against 1·2 per 1000 in the 96 large English towns. The deaths attributed to measles, which had been 17, 14, and 14 in the three preceding weeks, rose to 18 last week, and included 10 in Wexford, 4 in Belfast, and 2 in Newry. The deaths of infants (under 2 years of age) referred to diarrhœa and enteritis, which had been 8, 11, and 10 in the three preceding weeks, were again 10 last week, of which number 8 were registered in Dublin. The fatal cases of whooping-cough, which had been 10, 5, and 3 in the three preceding weeks, slightly rose to 6 last week, and included 5 in Dublin. Of the 5 deaths attributed to diphtheria, which were equal to the average in the five preceding weeks, 2 occurred in Dublin, 2 in Londonderry, and 1 in Belfast. The 3 deaths referred to scarlet fever were recorded in Belfast. In addition to the above diseases a fatal case of typhus was registered in Dublin.

The deaths referred to diseases of the respiratory system, which had been 122, 142, and 109 in the three preceding weeks, further declined to 92 in the week under notice. Of the 481 deaths from all causes, 152, or 32 per cent., occurred in public institutions, and 8 resulted from different forms of violence. The causes of 22, or 4·6 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 96 large English towns the proportion of uncertified causes of death last week did not exceed 0·9 per cent.

VITAL STATISTICS OF LONDON DURING MARCH, 1913.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the ten diseases specified in the table was equal to an annual rate of 4·8 per 1000 of the population, estimated at 4,518,191 persons in the middle of the year; in the three preceding months the rates were 5·5, 5·3, and 4·8 per 1000 respectively. The lowest rates last month were recorded in Hammersmith, Chelsea, Hampstead, the City of London, and Shoreditch; and the highest rates in Southwark, Bermondsey, Battersea, Wandsworth, Camberwell, Deptford, and Lewisham. The prevalence of scarlet fever showed a considerable decline last month; this disease was proportionally most prevalent in Poplar, Bermondsey, Lambeth, Battersea, Camberwell, and Deptford. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals, which had been 2088, 1717, and 1639 at the end of the three preceding months, had further declined to 1436 at the end of last month; the weekly admissions averaged 153, against 226, 196, and 189 in the three preceding months. Diphtheria was rather more prevalent than it had been in the preceding month; among the several metropolitan boroughs the greatest proportional prevalence of this disease was recorded in Paddington, St. Pancras, Stepney, Southwark, Bermondsey, Battersea, Wandsworth, Lewisham, and Woolwich. The Metropolitan Asylums Hospitals contained 901 diphtheria patients at the end of last month, against 959, 925, and 913 at the end of the three preceding months; the weekly admissions averaged 122, against 120, 122, and 118 in the three preceding months. The prevalence of enteric fever showed a slight decline last month; this disease was proportionally most prevalent in Paddington, the City of Westminster, St. Pancras, Bethnal Green, and Bermondsey. There were 42 enteric fever patients under treatment in the Metropolitan Asylums Hospitals at the end of last month, against 37 and 44 at the end of the two preceding months; the weekly admissions averaged 7, against 7 and 6 in the two preceding months. Erysipelas was proportionally most prevalent in Chelsea, Finsbury, Bethnal Green, Stepney, Southwark, Camberwell, Deptford, and Greenwich. The 31 cases of puerperal fever notified during the month included 7 in Islington, 3 in the City of Westminster, 3 in Finsbury, 3 in Stepney, 2 in Fulham, and 2 in Lambeth. The 11 cases of cerebro-spinal meningitis included 5 in Stepney; and the 2 cases notified as poliomyelitis belonged respectively to the City of Westminster and Hampstead.

The mortality statistics in the table relate to the deaths of persons actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the several boroughs in which the deceased persons had previously resided; the death-rates from all causes are further corrected for variations in the sex- and age-constitution of the populations of the several boroughs. During the four weeks ending March 29th the deaths of 6105 London residents were registered, equal to an annual rate of 18·5 per 1000; in the three preceding months the rates had been 12·5, 17·8, and 19·0 per 1000 respectively. The death-rates last month ranged from 12·4 in Lewisham, 13·4 in Hampstead, 13·6 in the City of London, 14·3 in Wandsworth, 16·1 in Holborn, 16·2 in Greenwich, and 16·3 in Fulham, to 20·1 in Bethnal Green, 20·5 in St. Marylebone, 21·2 in Islington and in Finsbury, 21·4 in Bermondsey and in Deptford, 22·2 in Southwark, and 22·7 in Shoreditch. The 6105 deaths from all causes included 506 which were referred to the principal infectious diseases; of these, 284 resulted from measles, 8 from scarlet fever, 34 from diphtheria, 93 from whooping-cough, 1 from enteric fever, and 86 from diarrhœa and enteritis among children under two years of age. The lowest death-rates from these diseases were recorded last month in Hampstead, St. Pancras, Stoke Newington, Holborn, the City of London, and Lewisham; and the highest rates in Hammersmith, St. Marylebone, Bethnal Green, Southwark, Bermondsey, and Battersea. The 284 deaths from measles were slightly below the average number in the corresponding period of the five preceding years; this disease was proportionally most fatal last month in St. Marylebone, Bethnal Green, Southwark, Bermondsey, Lambeth, and Battersea. The 8 fatal cases of scarlet fever showed a decline of 19 from the corrected average number, and included 2 in the City of Westminster. The 34 deaths from diphtheria were 15

† The death rates are corrected for variations in sex- and age-constitution of the populations of the several boroughs, the population of England and Wales being taken as the standard.

fewer than the corrected average number; this disease was proportionally most fatal in St. Marylebone, Stepney, Deptford, and Woolwich. The 93 fatal cases of whooping-cough were 53 below the corrected average number; the highest death-rates from this disease were recorded in Paddington, Hammersmith, Fulham, Finsbury, Bermondsey, Camberwell, and Deptford. Only 1 death from enteric fever was registered in London last month, the corrected average number being 10. The mortality from diarrhœa and enteritis among children under two years of age was proportionally greatest in Finsbury, Shoreditch, Stepney, Bethnal Green, and Bermondsey. In conclusion, it may be stated that the aggregate mortality in London last month from the principal infectious diseases, excluding diarrhœa, was 19·4 per cent. below the average.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

Surgeon-General A. W. May has taken up duty in the Admiralty Medical Department preliminary to taking over the Director-Generalship of the Department on May 11th.

Surgeon-General A. J. J. Johnston has succeeded Surgeon-General May in the medical charge of the Naval Hospital, Chatham.

In accordance with the provisions of His late Majesty's Order in Council of August 11th, 1903, Surgeon John McCutcheon has been allowed to withdraw from His Majesty's Naval Service with a gratuity (dated April 13th, 1913).

The successful candidates at the April examination for the Naval Medical Services, whose names were announced in THE LANCET last week (p. 1124), have been entered as acting surgeons and appointed to the *Victory*, additional, for a course of instruction at the Naval Medical School, Royal Naval College, Greenwich, and at Haslar Hospital.

ROYAL ARMY MEDICAL CORPS.

Captain David S. Buist is seconded for service with the Egyptian army (dated Feb. 26th, 1913).

Surgeon-General L. E. Anderson has been appointed to the Administrative Staff of the forthcoming Irish Command Staff tour.

Colonel H. M. Sloggett has been selected for appointment as Assistant Director of Medical Services to the Belfast District. Colonel F. J. Jencken has been granted one month's leave of absence.

Brevet-Colonel Sir William B. Leishman has been appointed a member of the Advisory Medical and Sanitary Committee for Tropical Africa.

Lieutenant-Colonel J. D. Ferguson, D.S.O., has been, selected for appointment to the Straits Settlements. Lieutenant-Colonel W. T. Mould has been granted three months' leave of absence. An exchange of positions on the roster for service abroad has been approved between Lieutenant-Colonel N. Manders, at the Curragh Camp, and Lieutenant-Colonel M. T. Yarr, of the London District, who will now proceed abroad during the coming trooping season. Lieutenant-Colonel F. W. Hardy has taken over charge of the Military Hospital at Allahabad Cantonment.

Major W. L. Bennett has been appointed to the Northern Command. Major H. A. Hinge has taken up duty in the Aldershot Command. Major P. S. O'Reilly has been granted eight months' leave of absence home from India. Major J. F. M. Kelly has arrived home for duty from Potchefstroom. Major G. Dansey-Browning has embarked for a tour of duty at Gibraltar. Major A. L. Scott has been transferred from Aldershot to Deepcut. Major J. Matthews has taken up duty at Secunderabad Cantonment. Major H. Herrick has arrived home on leave of absence from India. Major R. L. Argles has been transferred from Cahir to Tralee. Major E. F. Q. L'Estrange has been selected to command the Military Hospital at Cannanore. Major J. Poe has arrived home from South Africa. Major E. W. Siberry has been appointed to the London District. Major J. E. Brogden has been transferred to Malta from Gibraltar. Major W. P. Gwynn has been granted eight months' leave of absence home from Burma.

Captain A. G. Wells has been selected as Specialist in Operative Surgery to the Third (Lahore) Division of the Northern Army. Captain A. C. Vidal has arrived home for duty from South Africa. Captain A. Dawson has been appointed to the Irish Command. Captain T. E. Harty has been selected as Specialist in Dermatology and Venereal Diseases at the Military Hospital, York. Captain J. A. Clark has been selected for service with the Egyptian Army. Captain J. L. Wood has arrived home on leave of absence from Naini Tal. Captain H. Harding has taken up duty in the Eastern Command. Captain E. H. M. Moore has been transferred from the Military Hospital at Chatham to Shoeburyness. Captain G. De la Cour has been appointed to the Dublin District. The following Captains have been notified that they will be required for service abroad during the coming trooping season: L. Cotterill, J. McKenzie, A. H. Hayes, H. J. Crossley, R. Storrs, R. L V. Foster, J. A. Turnbull, J. G. Bell, T. S. Coats, and J. C. G. Carmichael. Captain F. R. Laing has embarked for a tour of service in India. Captain M. B. H. Ritchie has been transferred from the Military Hospital at Campbellpore to Mhow Cantonment. Captain F. A. McCammon has been appointed to the Irish Command. Captain G. B. Churchill has taken up duty at the Military Hospital, Bulford Camp. Captain A. W. Bevis has taken up duty in the Belfast District. Captain A. H. Bond has been transferred from the Military Hospital at Fermoy to Queenstown for duty. Captain W. Davis has taken up duty at the Military Hospital, Meerut Cantonment. Captain R. F. O'T. Dickinson has arrived home on leave of absence from Bareilly Cantonment. Captain G. A. K. H. Reed has been selected as Specialist in Physical Training to the Aldershot Command. Captain H. Stewart, Captain C. T. Edmunds, and Captain E. J. Kavanagh have been appointed for duty on board the transport s.s. *Plassy*.

Lieutenant R. B. Phillips has taken up duty in the Cork District. Lieutenant J. S. Levack has embarked for a tour of service in India. Lieutenant B. H. H. Spence has been transferred from the Royal Herbert Hospital to the Royal Army Medical College. Lieutenant G. O. Chambers has left Lichfield for a tour of service in Egypt. Lieutenant B. Biggar has been transferred from London to Windsor. Lieutenant J. M. Elliott has taken up duty at the Military Hospital, Hilsea.

INDIAN MEDICAL SERVICE.

Lieutenant-Colonel E. Wilkinson has been granted leave of absence from India for one year and nine months. Lieutenant-Colonel G. A. W. Hall has been selected for the increased rate of pay under Article 7 of the Royal Warrant for Pay and Promotion. Lieutenant-Colonel F. J. Dewes has returned to duty in Burma. Lieutenant-Colonel B. H. Deare has taken up temporary duty as Officiating Principal of the Medical College at Calcutta. Lieutenant-Colonel D. T. Lane has been appointed Civil Surgeon at Ambala.

Major R. Bryson has been selected for appointment as Officiating Surgeon to the First District Madras and Superintendent of the Royapuram Medical School in Madras City. Major F. V. O. Beit, on relief by Lieutenant-Colonel F. J. Dewes, has been selected as Civil Surgeon at Meiktila Cantonment, Burma, in succession to Captain H. W. Farebrother, R.A.M.C. Major L. E. Gilbert has been selected for appointment by the Government of Burma Major W. H. Kenrick has been granted leave of absence home from India. Major C. A. Sprawson has been selected for appointment as Professor of Obstetrics on the staff of King George's Medical College at Lucknow. Major Bhola Nauth has arrived in London on leave of absence. Major R B B. Foster has been selected as District Medical Officer at Malabar and Superintendent of the Lunatic Asylum at Calicut.

Captain L. Hirsch has been granted combined leave of absence home, with study leave, for one year and a half. Captain R. D. Saigol has been appointed Ophthalmic Surgeon to the General Hospital, Rangoon, during the absence of Captain E. A. Walker. Captain E. T. Harris has been transferred to Bassein. Captain J. Woods has arrived home on leave of absence. Captain S. C. Poe has been selected as Substantive Medical Officer to the 108th Regiment of Native Infantry, stationed at Bombay, in succession to Major W. H. Cox, D.S.O. Captain N. S. Simpson has been appointed to the Benares District as Plague Medical Officer, in succession to Captain J. S. O'Neill. Captain C. F. Marr has been granted an extension of his leave of absence.

TERRITORIAL FORCE

Royal Army Medical Corps

2nd Welsh Field Ambulance Royal Army Medical Corps. John Sydney Rowlands to be Lieutenant (dated March 12th, 1913)

Attached to Units other than Medical Units—Lieutenant Robert Lindsay to be Captain (dated Dec 5th, 1912)

For attachment to Units other than Medical Units—George Francis Raw [illegible]
Major, Cheshire Field [illegible]
Royal Engineers) to [illegible]
Josiah Walker to be Lieutenant (dated March 18th, 1913)

FLYING PAY FOR ROYAL NAVY OFFICERS

An Order in Council sanctions the following arrangements —(1) Medical officers who obtain the certificate of the Royal Aero Club at their own expense to be eligible for the gratuity of £75, provided the permission of the Admiralty to undergo such training has first been obtained, (2) medical officers trained at the Central Flying School or at a naval flying school to be paid half the authorised rate of flying pay while under instruction, (3) after attaining such standard of proficiency as may be laid down, medical officers to be paid the authorised rate of flying pay. (*a*) for any days on which they may be required to fly on duty, (*b*) for days on which it may be necessary for them to carry out practice flights, not exceeding two per month

HEALTH OF THE UNITED STATES ARMY IN 1911

[illegible]

ending June 30th, 1912 The mean strength of the troops was 72748 for whom the ratio of admission to sick report was 935 74 per 1000, the constantly non effective rate 33 28, the death rate 4 77, and the rate of discharge for disability (invaliding) 13 85 per 1000, the admission and constantly non effective ratios are the lowest hitherto recorded, and the death rate lower than in any previous year except 1910, when it was 4 46 per 1000 During and since the Spanish American war in 1898 exposure to tropical climates and the conditions consequent upon occupation of new territory caused considerable increase in sickness, this has been steadily diminishing with increase of knowledge *of tropical diseases and preventive medicine and the establishment of more sanitary conditions of living* in the recently acquired tropical possessions The bulk of the troops (55 240) serve within the area of the United States, their admission rate to hospital was 887 8 per 1000, while the ratio for "discharge on certificate of disability" and the death rate were 15 0 and 4 72 respectively In the Philippine Islands the garrison consisted of 12 454 men, for whom the respective ratios were 1218 24, 11 64, and 5 30 In Hawaii were stationed 2014 troops, with corresponding ratios of 1080 44 13 9, and 2 98 In Alaska the garrison consisted of 1119 men, with an admission rate of only 418 23 per 1000 and a discharge rate of 4 47, the *death rate* however, was 6 26 per 1000 A table of the rates for death and discharge (i e, invaliding) in the army of the United States compared with the armies of other Powers shows that the American death rate in 1911 (4 72) was higher than that of any of the other armies noted—viz British (in the United Kingdom) 2 42, French, 3 75, *Prussian*, 1 78; *Bavarian* 2 26, *Spanish*, 3 71, Russian, 4 07, Japanese, 3 57 The discharge or invaliding, ratio (15), on the other hand was lower than that of any other army except the British (11 07), the other ratios are French (35 34) Prussian (41 1) Bavarian (49 3) Spanish (44 2), Russian (41 7) Japanese (26 94) [illegible] refer to 1909 For the British [illegible] ed In 1911 the British ratios [illegible] 78 invaliding discharges per 1000 Another interesting table shows the comparative prevalence of certain diseases in various armies Ty[illegible] fever caused 0 80 admissions per 1000 and 0 11 d[illegible] per 1000 in the United States army In the Br[illegible] army (at home and abroad, 1910) the admission [illegible] was 2 2, in the French army (1909) it was 2 95, the Spanish, 3 24, in the Japanese, 5 47; and in the Russian 5 6 per 1000, while in the Austro-Hungarian army *the ratio was only 1 3, in the Prussian 0 35*, and in the Bavarian only 0 21 per 1000 The typhoid death rate in the British army (at home and abroad, 1910) was 0 28 per 1000, in the French it was 0 47, Spanish, 0 82, Japanese 0 55, Russian, 0 78, in the Austro Hungarian, 0 20, Bavarian, 0 06, and Prussian *only* 0 03 *per 1000 Of the causes of* death in the American army tuberculosis comes first with a ratio of 0 52 per 1000 strength After this measles, 0 45, pneumonia, 0 32, organic heart disease, 0 29, typhoid *fever*, 0 11, *tertiary syphilis*, 0 11

Typhoid fever has markedly decreased within recent years among the troops in the United States There were 44 cases with six deaths in 1911, the ratios per 1000 being 0 76 and 0 10 respectively The corresponding ratios for 1910 were 2 42 and 0 17, and for 1909 they were 3 03 and 0 28 There was no epidemic prevalence, the greatest number of cases at any one station being five at Fort Logan, Colorado In the Philippines there occurred 12 cases (0 88 per 1000) with no death Antityphoid vaccination is now practised universally, the prophylactic being administered to all officers and men under 45 who have not had the disease or already received protection It is considered that immunisation by this means is a thoroughly practical measure, and its protective value only second in importance to vaccination against small pox. In the Philippine islands in 1910 there had been 31 cases *among American troops with 2 deaths*, and 13 among native troops with 1 death In 1911 there were 12 among American and 12 among native troops with no deaths A large number of the American troops had been immunised, but none of the natives Hence probably the reason for the greatly reduced incidence among the former, while *among* the latter *there was no obvious improvement* Typhoid prophylaxis is now also compulsory in the United States Navy

Venereal diseases unfortunately, show no decrease in 1911 compared with the previous year, in spite of the efforts made to instruct recruits, to prevent exposure to infection, and to prevent infection after exposure The admission ratio was 185 13 (compared with 174 95 in 1910) and the constantly sick rate 10 14 (compared with 11 51) Gonorrhœa and chancroid have diminished but the number of syphilis cases has increased owing to the use of the Wassermann reaction which has revealed the syphilitic nature of many cases not previously recognised Prophylactic measures have been energetically carried out by means of the Slee *tube (calomel ointment and solution of argyrol or protargol), or by means of a disinfectant ointment (calomel phenol* and camphor) devised by Colonel L. M. Maus In certain areas "physical examinations" were made of all unmarried enlisted men fortnightly with the view of detecting venereal disease The preventive measure most advocated by army surgeons is that known as the "hospital method" this consists in a thorough cleansing after exposure to infection, with injection of argyrol or protargol, carried out at hospital by one of the hospital staff At Jefferson barracks it was found that only 15 infections occurred among 1675 prophylactic treatments, indicating a degree of *protection greater than* 99 *per cent* The opinion both of commanding and of medical officers is almost unanimous in favour of punishment and stoppage of pay in venereal cases The Secretary for War concurs in this opinion and recommends legislative action to carry it into effect Congress has now enacted that absence from duty "on account of disease resulting from intemperate use *of drugs or* alcoholic liquors or other *misconduct*" shall entail loss of pay for the period of such absence This stoppage of pay will, it is believed, do more than anything else to lessen the venereal rate in the army Malarial fevers continue to decrease steadily in prevalence In 1907 the admission rate was 31 per *1000* for white troops, *in* 1910 it was 17, in 1911, 15 47 In 1902 the ratio was as much as 96 per 1000 Fort Washington had the highe[illegible]t admission rate in 1911—viz, 333 per 1000 The post is surrounded by dense brush and timber, and continuance of [illegible] table unless vigorous measures are [illegible] n of the surrounding country [illegible] prevalent in 1911 than in the [illegible] 89 admissions per 1000 and [illegible] tios [illegible] 0 25 [illegible] The loss by discharge from [illegible] 2 85, compared with 4 01

Vancouver barracks at Washington showed the high admission rate of 21·96, exceeded only by the stations of San Francisco (41·20) and Fort Bayard, New Mexico (64·00). At this latter station there is a special hospital for the treatment of this class of cases, which appears to account for the high admission rate of the post. For alcoholism the admissions were 20·31 per 1000, a material improvement on the preceding year, when they numbered 23·51, and a lower ratio than in any year (except two) since 1870.

In regard to sanitation, it is noted that to each divisional headquarters a medical officer has been asssigned as "sanitary inspector" to assist the chief surgeon. The institution of a fortnightly "physical inspection" of the troops is also an important measure. The inspection includes examination of the teeth, of the body and clothing, of the feet and footwear, and in addition the detection of venereal diseases. The service cap that has been in obligatory use is of such a pattern that the top of the crown fits directly on to the head: it is therefore obviously unfit for use in hot climates, and in consequence of medical recommendations the wearing of the campaign hat has now been authorised during very hot weather. As the result of inquiries and trials by a board, presided over by Major E. L. Munson of the Medical Corps, a new pattern of shoe (by which, we presume, is meant boot, in our phraseology) has been evolved, which is stated to be most satisfactory; hitherto the supply of shoes of each size and width has not been sufficient at the various army posts to enable company officers to fit their men properly; also, it appears that recruits have been furnished with only a single pair of boots on enlistment. This defect has now been remedied. An interesting observation is recorded by Major Ashford as to the occurrence of uncinariasis at Porto Rico. Fifty men were found to have ground itch as the result of a single practice march. Microscopic examination of fæces was made immediately, and ova of uncinaria were found in 30 cases; the remaining 20 men were examined every ten days thereafter until ova appeared, as happened in 18 cases. None of these men had exposed their bare feet to infestation, but all were undoubtedly affected by muddy water, which had percolated through their shoes and leggings. There would seem to be no preventive but the wearing of rubber boots, which would be impracticable.

The improvement in the health of the troops in the Philippine Islands continues; there was, however, an admission rate of 1218·24 per 1000. The average constantly sick rate was 43·15, slightly lower than in 1910, when it was 45·45. The chief causes of sickness were venereal diseases (305 admissions per 1000), dengue (115·9), and malarial fevers (75·56). As a result of change in dietary beri-beri has practically disappeared from among the native troops. In 1908 the admission rate was 121·5 per 1000; in 1909 it was 103·9; in 1910 it dropped to 11·0, and in 1911 it was 0·57 per 1000; there were only 3 cases. The Tropical Diseases Board reported in 1911 that the neuritis-preventing principle of the rice extract must be contained in that portion of the solids which is dialysable; is soluble in water, in 95 per cent. alcohol, and in 0·3 per cent. hydrochloric acid; is easily decomposed by heat, and possesses a strong affinity for bone black. The same or a similar substance is contained in a decoction of white beans. In a report of January, 1912, the Board states that this principle is not phosphorus, is insoluble in ether, is absorbed by animal charcoal, and cannot be removed from the charcoal by maceration with water, absolute alcohol, or ether. Fifteen nursing infants suffering from the disease (as were their mothers) were treated with 20 drops of an extract of rice polishings every two hours while awake. "The results were truly marvellous. Improvement is immediate. The vomiting stops in 24 to 36 hours. The child, who has not passed any urine for several days, urinates five or six times freely. The œdema disappears in the course of a few days. ...... It can be said that this extract is a 'cure' in the true sense of the word, just as lime juice is a 'cure' for scurvy." It has been known for some time that the ultra-violet rays of the spectrum kill bacteria in a few seconds, and water sterilisers on this principle have been constructed by the Westinghouse Cooper Hewitt Company, of London and Paris. Recent experiments by the board show that these rays also destroy amœbæ, whether motile or encysted, and balantidia; and further tests of the practicability of using these radiations in water sterilisation are being carried out. Experiments on the fineness of mesh necessary to keep out mosquitoes showed that 16 mesh netting kept out all malaria carriers in the Philippines, but did not keep out stegomyia calopus, an extremely annoying species and a potential source of danger in case yellow fever should be introduced into the archipelago. Many other topics of interest are dealt with in this report, which is of great value to sanitarians and epidemiologists. It is most admirably printed.

ARCHIVES DE MÉDECINE ET PHARMACIE NAVALES

In the January number is a long and interesting account of the explosion in the *Liberté* at Toulon on Sept. 25th, 1911, from the pen of Dr. Gazeau, apparently principal medical officer of that fleet, a deputy surgeon-general. On the day in question, at about 5.30 A.M., several muffled explosions were heard by the fleet in the fore part of the *Liberté*, and smoke was seen coming from the port fore casemate, soon replaced by flames. There was at first a panic on board as the wounded came groaning from below, but this ceased when the men were sent to fire stations, and some who had gone overboard swam back to the gangways and climbed inboard again. Boats were sent from other ships, but as the fire was not got under it was obvious there would be another explosion. The pumps of the *Liberté* were put out of action by the explosion, and the chief petty officers, who were struggling with the flooding valves, died suffocated at their posts. The second explosion came at 5.53. The upper works of the great ship opened and lifted, a column of smoke and fire shot up to the sky and a pall of smoke fell back and for a few moments hid the disaster from the fleet. Not that they had time to gaze merely; 83 of their own people had been killed and 164 wounded by flying scraps from the *Liberté*, or were drowned or struggling in the water by the ruin of their boats, and these had to be rescued. The wounded were looked after by the medical officers on guard (four are mentioned in a fleet of 20 ships), and were then sent to the Naval Hospital, St. Mandrier. The injuries of the men of the *Liberté* were remarkably uniform, mainly contusions of the head. Apparently, as the decks were burst up by the explosion, those standing on them were thrown violently against the deck above and so got the contusions. Then they ran the risk of suffocation or of drowning when thrown overboard in a state of shock. After fractures of the vault, the most frequent class of injury was burns, and then fractures of the limbs. Many suffered from multiple injuries. One man was found still alive in the wreck of the *Liberté*; to free him from the wreck it was necessary to amputate his foot which was jammed between two pieces of iron, but he died from fracture of the skull when on the way to hospital. The bodies were very carefully identified; those that could not be removed were injected with formalin and covered with a lime paste. The last to be removed, five months later, was then able to be identified. A quartermaster of the *Foudre*, with a small wound of the back of the right chest, died with purulent pleurisy, and at the necropsy a rivet was found on his liver with pieces of his shirt and jersey. No case of carbonic oxide poisoning was reported amongst the injured, nor any of intoxication by other products of combustion of nitro-powders.

THE MILITARY SURGEON.

In the *Military Surgeon* (Chicago) for March Captain L. C. Duncan gives an account of the work of Letterman, who is held in honour in the army of the United States, as Larrey in the French service. Letterman appeared on the scene in July, 1862, as McClellan's principal medical officer. Armies had become too large to be managed on any system developed from the regimental. The medical system was regimental and was discredited. The wounded from Bull Run in July, 1862, had remained, some of them, three days on the field without food or shelter. There was no medical organisation behind the regiment. Letterman saw where the mistake lay, took their ambulances away from the regiments and gave them to the ambulance corps, whose business it was to collect the wounded and take them to the field hospitals he also established. In December, at Fredericksburg, by the new system 10,000 wounded were taken off the field in the first night. Letterman's predecessor gave a most ridiculous but instructive opinion on regimental hospitals, which he considered just the thing unless the army were on the march or in battle. In other words, he preferred the organisation he knew to be only fit for peace time and did not prepare for the needs of war as one would have expected. Captain A. G. Love, Medical Corps, U.S. Army, shows the rapid decrease in enteric fever in the army in India, which he ascribes to antityphoid inoculation. Theirs, in the United States army, is, he nevertheless states, more effective, as they use an agar, not a bouillon, culture, and inject patients thrice, not only twice. (It is interesting to note that Captain A. H. Hayes, R.A.M.C., discussing these same figures,[1] ascribes the fall in enteric fever rates (1) to antityphoid inoculation; (2) to sanitary administration; but (3), and above all, to the segregation of enteric convalescents at Naini Tal and Wellington.) An excellent article on armies, and the medical officers' work, by Lieutenant-Colonel W. B. Banister, Medical Corps, U.S. Army, will repay perusal.

THE MEDICAL MANŒUVRES IN INDIA.

The *Allahabad Pioneer* and other prominent Indian papers commenting on the recent medical manœuvres held at Rawal Pindi under the direction of Lieutenant-General Sir James Willcocks, commanding the Northern Army in India, draw attention to the great need of the army in India for trained and disciplined *dhoolie* bearers. In order to complete the bearer *personnel* of *one* division alone, some 600 hired coolies had to be collected from the Rawal Pindi bazaars; and, as might have been expected, they were in no way fitted either physically or otherwise for their duties. Some of them deserted at an early stage of the manœuvres, while when a deluge of rain fell on the third day of the operations the men told off to two Field Ambulances vanished altogether. The experience thus gained was a very valuable one, and it is obvious that proper measures will have to be taken by the military authorities to remedy this grave defect in organisation that has been disclosed The case of this one division is typical of what would happen with the whole ten divisions of the Indian army, and we cannot run the risk of Indian Field Ambulances being stranded in the field for want of bearers to carry the sick and do other duties. The Army Bearer Corps will have to be expanded and put on the proper footing it had when Colonel D. Shearer initiated it under the orders of Lord Kitchener.

THE ORDER OF THE HOSPITAL OF ST. JOHN OF JERUSALEM.

Among the recipients of the Service Medal of the St. John Ambulance Brigade at a special meeting of the Chapter-General of the Order of the Hospital of St. John of Jerusalem, presided over on April 22nd by the Grand Prior, the Duke of Connaught, were District Surgeon E. B. Pooley, Corps-Surgeon and Superintendent J. Broomhead, and Corps-Surgeon R. Clegg.

Correspondence.

"Audi alteram partem."

THE GERMAN MEDICAL STUDY TOURS.

To the Editor of THE LANCET.

SIR,—The following communication from the German Central Committee, which organises tours abroad for purposes of medical study, has been addressed to me as President of the General Medical Council. I shall be obliged if you will give it publicity, and I express the hope that the medical authorities and the profession generally may be prepared to offer a welcome to our German brethren when in August they visit the localities mentioned.

I am, Sir, yours faithfully,
London, W., April 21st, 1913. DONALD MACALISTER.

[ENCLOSURE.]

"The German Central Committee for Medical Travel has the honour to inform you that the programme for this year's tour, in connexion with the meeting of the International Medical Congress in London, includes visits to England, Scotland, and Ireland. The following places will be visited: London, Scarborough, Leith, Edinburgh, Aberdeen, Stornoway, Oban, Glasgow, Belfast, Dublin, Jersey, and Guernsey.

"In intimating this visit, we would add that the German Medical Study Tours, which have now been in operation for 13 years, and in which over 3000 German and other practitioners have taken part, are intended to subserve purely scientific purposes.

"We request you, therefore, as President of the General Medical Council, to be good enough to further our objects by informing the profession of our intended visit, in order that in the various localities indicated we may have the privilege of access to, and inspection of, universities, hospitals, hygienic and philanthropic institutions, sanatoria, &c.

"We send a copy of our constitution and list of members, from which you will gather the composition of our committee.*

"With thanks in advance for your kind coöperation and with the expression of our distinguished regard,

"I am, very sincerely yours,
"Sanitätsrat Dr. A. OLIVEN."

* Presidents: Professor Dietrich (Berlin), Professor Glax (Abbazia), Professor His (Berlin), Professor von Strümpell (Leipzig). General secretary: Dr. A. Oliven, 134B Potsdamer Strasse, Berlin W. 9, to whom inquiries and invitations should be addressed.

THE ROYAL COMMISSION ON UNIVERSITY EDUCATION.

To the Editor of THE LANCET.

SIR,—In your very able leading article of to-day on the Report of the Royal Commission on the University of London you say: "They propose no concentration into two or three institutes of instruction in anatomy, physiology, and pharmacology, recognising the obvious advantages of training the medical student in these early professional subjects at places where he is in touch with clinical and pathological work."

I read the report rather differently, for Section 279, which deals with this part of the recommendations, definitely states that the "intermediate medical sciences should be in close connexion with the medical college," at which clinical instruction is given. Inasmuch as elsewhere the report contemplates the selection or foundation of three centres at which clinical instruction will be given, it seems obvious that there will also be three centres for the teaching of the intermediate subjects and we are expressly told in the same section that two of these centres "must for the time at least" be University College and King's College.

While it is true that the new scheme does not entail the separation of intermediate from clinical teaching, it does seem to revive in the most definite way the three-centre policy of concentration as it affects intermediate teaching, and reasserts the claims of University and King's Colleges, which, in the opinion of the late Sir Henry Butlin and many other supporters of the original scheme for concentration, really wrecked that scheme. Sir Henry Butlin very clearly stated the position in his evidence (Third Report, p. 276). When it became clear, in 1906, that University College and King's College were to be two of the three centres contemplated for the teaching of preliminary and intermediate subjects—

Because the schools objected to being forced to give up to two competing rivals a number of their best students, they are accused by the Commission of "jealousy" towards King's and University Colleges. The charge reminds one of the ancient couplet—

Le chat est un animal méchant,
Quand on l'attaque il se défend.

The *méchanceté* of the schools is certainly not likely to decrease when they learn that the despoiling of their advanced students is to be added to the despoiling of their intermediate students, and that their present representation on the Faculty of Medicine, by which they have been able in the past to defeat this particular encroachment, is to be taken away while being reserved for the collegiate teachers.

---

[1] Journal of the Royal Sanitary Institute, March, 1913, p. 118.

The report invites criticism on many other points: I select this one issue because your scrupulous fairness and impartiality lend authority to a statement which I do not think can be sustained by reference to the report. Intermediate teaching is to be sequestrated from all the schools except University College, King's College, and one problematic and unnamed third school, if this Commission has its way, I am, Sir, yours faithfully,

London, W., April 19th, 1913. E. GRAHAM LITTLE.

THE MEDICAL PROFESSION IN INDIA.

To the Editor of THE LANCET.

SIR,—In THE LANCET of March 8th you have in a leading article commented on the relations between the Indian Medical Service and the non-official practitioners of India, and your conclusions are frankly dependent on the views of a Special Correspondent who is "intimately acquainted with the facts." If I can show you that his "facts" are often incorrect and his implications as frequently unfair, I trust you will feel at liberty to reconsider your views. I propose to deal with that part of the service in which I am working, not because I believe that the case there is any stronger than it is in other parts, but because I can give you facts regarding it at first hand. I trust that you will accord to my communication an equal publicity to that given to the remarks of your Special Correspondent.

He divides the ordinary run of I.M.S. officer in civil employ into district surgeons and civil surgeons, and is indeed at some pains to prevent their being confused. This is his first inaccuracy. The whole of British India is divided into districts, and each district contains in the vast majority of cases one I.M.S. officer only. In Madras he is called the "district medical and sanitary officer," and over the rest of India "the civil surgeon." These are merely different names for officers performing the same duties. There are in Rangoon two civil surgeons, who are, I believe, practically presidency surgeons, and there are a few cantonments in which an officer in military employ is given the title of civil surgeon; but apart from these I know of no instance where the civil surgeon is not in charge of a district. This error does not imply an intimate acquaintance with the facts.

The second matter on which no man "intimately acquainted with the facts" would make an error is in stating that the usual fee in India is Rs. 15. Certainly over the whole of the north of India it is invariably Rs. 16.

The third matter is an omission, and a serious one in face of the statement that the medical cost of a lengthy illness is not inconsiderable. I refer to the system taken advantage of by most Europeans and some Indians of paying a fixed yearly sum to the civil surgeon for the care of their families, whether well or ill, a form of insurance which is usual and which entails no hardship on anyone.

This leads naturally to the fourth mis-statement, made and repeated—namely, that families of Government servants are in certain cases entitled to the free services of the civil surgeon. Civil Government officers are not entitled to the services of any medical officers for their families, though military officers are; so that the affecting picture of the official paying in disgusted silence the reluctantly attending civil surgeon in order to induce the latter to give more willingly a service to which the former is entitled as a right for his family is entirely a work of imagination. This, however, does not make the implication any the less galling, even though it is accompanied by the obviously false imputation that the official in India is not sufficiently honest to see anything dishonourable in drawing a hugely inflated travelling allowance toll.

Fifthly, we come to another affecting picture—that of the subordinate who is not entitled to the services of the civil surgeon, but requires them, pays for them, and is silent. The sting is in the word "silent." It implies that there is something underhand about the proceeding. Of course there is not. Is the civilian doctor, who is, we are told, going to replace the service officer, going to treat for nothing any but those entitled to his services? Of course not. The position is precisely that which obtains in England: there is always the hospital for those who cannot pay, and where the civil surgeon may be consulted by the poorest. As a matter of fact, hospital abuse is becoming a very serious factor in India, and is a matter on which the independent medical practitioner of India has a very real grievance against hospital officers, although your correspondent gives no indication of the fact.

Sixthly, it is necessary to speak plainly on the matter of colour. Your correspondent imagines that the white population will not be averse to a stationary civilian surgeon. Obviously, if the independent profession is to be local, this officer will in nearly every case be an Indian. You may or may not sympathise with it, you may or may not understand it, but you cannot ignore the intense repugnance with which the European in India views the suggestion that his wife should be examined and conducted, let us say, through a confinement by an Indian. The matter introduces far-reaching political questions on which I have no intention of touching, but I have had to introduce it in order to give your correspondent's suggestion a flat contradiction.

Seventhly, we come to what is really the crux of the whole matter. I refer to the two statements which supplement and explain one another—namely, first, that the interests of the I.M.S. and of the independent local profession are opposed to one another; and, secondly, that "it must be understood that he (the civil surgeon) acts in most cases as a general practitioner in attendance on the patient and not merely in a consultative capacity to his subordinate." It is no use my giving merely a direct denial to this statement; it can only be controverted by facts, and there is no possible way of presenting these except by giving a personal experience. The station and district of which I am civil surgeon is acknowledged to be a "good" one. I divide my patients into two sets, European and Indian. To Europeans I frankly act as a general practitioner; and were I not a medical man I should strongly resent any suggestion that I and my family should be treated in any other way. My practice among Indians is, as practices outside the Presidency towns now go, a "good" one, but in spite of this fact I have seen, since I came here about 17 months ago, three Indian patients, and three only, to whom I have not been called as a consultant by a member of the independent local profession. All these cases had come in from the district urgently ill, and obtained my advice before calling in one of the general practitioners of the town. I did not see them again except in consultation. With the exception of these three visits and of the household of a Government ward, who has been placed by Government directly under the care of the civil surgeon, I have not seen an Indian here except in consultation. My practice among Indians depends entirely upon my being called in by members of the independent local profession, either at their own instance or at that of the patient or his friends, and I may add that any reduction of my usual fee is entirely at the discretion of the practitioner who calls me in. I absolutely deny any opposition in interest between myself and the members of the independent local profession. I absolutely deny that "their efforts at private practice are frustrated by the existence of the subsidised private practitioner of the Government" as represented by myself. On the contrary, I merely provide them with the consultative aid which they wish, and which both they and their patients have every right to get. To refuse to the sick and to their medical attendants consultative aid from one who is in nearly every district marked out by experience and qualification as the person best able to give it, would surely be an act of folly and one which would be strongly resented by the very people whom it is supposed to benefit. It would seem that your correspondent is disposed to look on the improvement of the local independent profession as an end, and not as merely a means, towards the betterment of the lot of the sick Indian. Would anyone in England seriously suggest that the public should be debarred from the advantage of the experience gained by the physicians and surgeons of our great British hospitals, unless they be hospital patients? You cannot justly suggest that conditions should be different in India.

If the facts I have given were singular they would have no value. I am only, however, one of many in precisely similar case, and I have merely brought in those personal matters as being the only way of showing that your correspondent most decidedly is not "intimately acquainted with the facts" He has not been fair to the Service either in fact or in implication If the I M.S officer is debarred from private practice his suggestion obviously is that you will get an equally good man as a consultant If the matter is reasoned out it comes to this Is it to be expected that you will get the same professional standard from a man who is to be dependent entirely on the fees now made by the civil surgeon, as from one who has both his pay and fees to live upon? One can scarcely expect to get in the future an article of equal value for from half to one third of the cost now paid As a matter of fact it would not suit those who want later to replace the Indian Medical Service officer as civil surgeon to have the right of private practice now taken away from the civil surgeon.

Your Special Correspondent is not only inaccurate, but he is also ungallant, for he has entirely omitted all mention of the ladies In this part of India the purdah system is dying, so far as doctors are concerned. The lady doctor is nearly always in direct competition with the male, except in the matter of obstetric and gynæcological work, and even here the man is coming in so rapidly that the woman's monopoly will, in my opinion, be broken by the time that the next generation has grown up Possibly to his ignorance in other matters your Special Correspondent adds that of the fact that the suffragette has not yet invaded India, so that he has covered his rudeness to the ladies by taking refuge behind the purdah of anonymity

I am, Sir, yours faithfully,
Clayton Lane, M D Lond ,
Berhampore Bengal April 2nd, 1913 Major I M.S , Civil Surgeon.

THE POSITION OF ASSISTANT MEDICAL OFFICERS IN ASYLUMS.

To the Editor of The Lancet.

Sir,—Your anonymous correspondent who signs himself "Reform," writing in The Lancet of April 12th on the above subject, states that "in nearly all asylums even a minor operation requiring an anæsthetic is performed by an outside surgeon specially employed" He adds that "in few asylum infirmaries is there any trained nursing as ordinarily understood," and he emphasises the disadvantages generally of asylum service owing to the "infrequent vacancies for superintendents" Whilst deprecating the tone of "Reform's" letter may I quote an extract from my report of last year relating to the Claybury Asylum to the committee of the London County Council responsible for its administration. It is as follows "Of the medical officers who have served here, seven are medical superintendents of asylums in England and Wales (I might add, with salaries commencing at from £500 to £1000 a year, and a pension after so many years' service or attaining the age of 55 years) and of the other officers six are clerks or stewards or both eight are or were matrons of other institutions five of them being in the London County Asylums In addition, there are many of our staff enjoying high promotion in at least five other places at home and abroad" In addition to the above medical officers there are several enjoying lucrative private practices, and tasting prosperity both at home and abroad Although this is a satisfactory record it is not the best, as one other of the London Asylums boasts of even a greater success for its assistant medical officers During last year which is the twentieth year of the history of the asylum, the following operations were performed by the medical staff of the institution (1) An operation for the relief of traumatic epilepsy by trephining the skull at the site of a scar over the left frontal area (the patient later was able to be transferred to his friends in Australia), (2) for the relief of strangulated hernia, (3) a similar operation upon a male patient aged 82 years, (4) for symptoms of internal strangulation, (5) for chronic periostitis of the femur; (6) for the excision of extensive tubercular glands in the neck, (7) for a troublesome double inguinal hernia with occasional symptoms of strangulation, (8) for a volvulus of the sigmoid flexure, (9) for cataract, (10) for inguinal colotomy to relieve a cancerous stricture which gave her eight months of life in comparative comfort, and (11) for internal strangulation caused by a band Only one operation, and that for prostatectomy, was performed by an "outside" surgeon. In addition to the above, there were many minor incidents requiring either a local or a general anæsthetic As to the "monotonous leisure," several of my younger colleagues have taken their M B, M D, and F.R C S degrees or diplomas, and one obtained a gold medal at his M D thesis during this monotony.

The greatest enemy to any institution is "the idle man" whom the sage of Chelsea described as "the one monster in the world" I consider that a short experience of life in a large institution is the most useful service that any young practitioner can experience It teaches him the usefulness of "give and take"—the man of compromise in the long run gets most of his own way—the necessity for method, the value of organisation, the great importance of moral treatment, the therapeutic value of various remedial agencies perseveringly administered He can investigate morbid phenomena under conditions rarely met in "outside" practice, and he can engage in research connected with the body or the mind in a way that will not only interest him but will recompense him for his study and observation If medical officers, as they do in my experience devote themselves to the better training of their nurses asylum infirmaries should become places where the best treatment and the best work can be seen, work which is destined to become more appreciated than has been the case in "Reform's" experience I agree with the writer that the service should be improved in every way possible, and a paper read before the Medico Psychological Association recently by Dr J B Spence aims at efforts in this direction In the meantime, I trust the best men will not be discouraged from entering asylum service by the pessimistic record of your anonymous contributor

I am, Sir, yours faithfully,
Robert Jones, M D Lond
Claybury Asylum Woodford Essex April 15th, 1913

To the Editor of The Lancet

Sir,—Dr F R P Taylor seems to have been fortunate in his lengthy experience of asylums but many of his statements would appear to merit a somewhat closer examination It is quite true that the assistant medical officers give lectures to the staff on their general duties, and a man's personality and abilities may do much The female staff, however, are mainly recruited from the domestic servant class and the male staff from agricultural labourers, ex privates in the army &c Most excellent people, indeed, but often very deficient in the preliminary education so necessary if they are to benefit from instruction in nursing The population of an asylum is, in the nature of things, largely a healthy one, and junior medical officers in the larger institutions, when not in charge of the infirmaries, see little serious illness in many of the sections The infirmaries are organised for dealing with the sick, and it is there they go, and properly so from every point of view, except that of the man looking for experience that may be useful afterwards I am sure Dr Taylor has seen occasional operations performed by the staff Such opportunities do not occur three times a year, and therefore what use are they as a training? Midwifery is practically non existent, and infectious disease, with the exception, perhaps, in some places of colitis and an occasional phthisis case, is infrequently seen Greatly to the credit of the management a serious accident is one of the rarest things imaginable Is this a training for a general practitioner? Does the study of the mental peculiarities of his patients compensate him for the time spent away from the real work of general practice, and in spite of his access to a laboratory, if it is his intention not to continue lunacy work would he not be better employed either in the wards of a general hospital, Poor-law infirmary, or assisting a senior man in general practice? I can only repeat what I said before, that lunacy work has little reference indeed to general practice and is a very poor training for it

I am, Sir, yours faithfully
Reform.
April 18th, 1913

To the Editor of The Lancet

Sir,—I quite agree with the remarks made by "Reform" All assistant medical officers are not so fortunate as Dr F R P Taylor, who evidently has been encouraged to work I myself was in one of the Metropolitan Asylums Board asylums for nine months. There were three assistant medical officers, and surgical work was discouraged. One example is sufficient. A patient on the female side had a strangulated hernia, and the senior assistant medical officer and myself decided to operate. The medical superintendent was present. A general anæsthetic was administered, and I attempted to reduce by taxis; that failed. Everything was ready, and I asked the sister for a scalpel. The superintendent would not allow me to proceed further. He admitted that he could not operate himself, but thought I was too young, so to save the situation he called in an outside doctor. The doctor came in about seven hours, and after a "consultation" with the superintendent deemed it would be unwise to operate, as the patient was just dying. The patient lived for 36 hours after that.

Naturally the whole proceedings were revolting to me, and I did not remain longer in the service than I could help, neither did the superintendent encourage me to remain.

I am, Sir, yours faithfully,
April 19th, 1913. SYMPATHETIC.

MEDICAL OFFICERS OF HEALTH (SUPERANNUATION) BILL.

To the Editor of THE LANCET.

SIR,—From all parts of England and from the north of Scotland replies to my letter in THE LANCET of April 12th have reached me. Every one of them strongly urges the necessity of including in the Bill school medical inspectors and tuberculosis officers. Widespread discontent with the remuneration at present offered, especially to school medical inspectors, is almost invariably commented on in these replies. Those who have written have also brought the Bill to the notice of their Members of Parliament.

I have sent the appended letter to Sir Philip Magnus (presenter of the Bill), Sir Henry Craik, Mr. Lough, Mr. Charles Bathurst, Sir Henry Norman, Mr. Godfrey Locker-Lampson, and Mr. Glyn-Jones, supporters of the Bill:—

I have the honour to request your attention to, and consideration of, the following amendment, which, I hope you will see, has a strong claim for insertion in the Bill during the Committee stage.

Amendment:—

That the words "Medical Officers of Health" in the title and throughout the Bill include "School Medical Inspectors and Tuberculosis Officers."

Reasons:—

(1) Medical Inspectors and Tuberculosis Officers have salaries ranging on the average from a fourth to a half of that paid to Medical Officers of Health.
(2) Being whole-time officers they are precluded from augmenting their salaries by engaging in other work.
(3) About 3 out of every 4 Medical Inspectors and Tuberculosis Officers will not receive promotion from their present position because their numbers are so much greater than those of Medical Officers of Health.
(4) They form the junior branches of the Public Health Service.
(5) All the arguments adduced in the Bill in favour of Public Health Officers apply in the case of Medical Inspectors and Tuberculosis Officers.

A copy has also been sent to the Secretary of the Society of Medical Officers of Health, to the Secretary of the British Medical Association, and to Dr. Addison.

I am, Sir, yours faithfully,
ALEXANDER GRAHAM,
West Ham, E., April 21st, 1913. School Medical Inspector.

PROFESSOR BIEDL'S TREATISE ON "THE INTERNAL SECRETORY ORGANS."

To the Editor of THE LANCET.

SIR,—I should not have deemed it necessary to reply to Professor Biedl's letter in your issue of April 12th were it not that the whole transaction contains a lesson both to translators and publishers, of which they will do well to take heed.

The facts related in my letter which appeared in your issue of April 5th are not in dispute. Professor Biedl now supplies some further facts, from which your readers are apparently intended to infer that I undertook to do the translation, and failed to make good my undertaking. This is not the case. The English publishers asked me to translate the book into English. To this I replied that I had no time for such an undertaking, and referred them to Mrs. Linda Forster, who by her translation of Professor Max Braun's "Handbook of Practical Parasitology" (Bale and Sons, 1910) and other foreign scientific works had proved herself a careful and accurate translator with a lucid and agreeable English style. Mrs. Forster consented to undertake the responsibility on the condition that she might seek my opinion on doubtful points; and to this I agreed.

Then followed the happenings which I recounted in my last letter; Professor Biedl's corrections, sometimes helpful, but more often hypersensitive, of the translator's rendering of the original text, but also, and far more frequently, his painstaking Germanising of her English; the translator's protest; the Professor's insistence; and, finally, the crowning discipline of reconverting the professorial corrections into idiomatic phraseology. In such circumstances it is not surprising that some mistakes should creep in. But then translators are notoriously unreasonable people; they have no sense of propriety.

Nor, seemingly, are publishers much better, as witness the behaviour of the English publishers in the matter of the preface. They begged me, these misguided people, to write a foreword to the English edition—an honour which, as in humility bound, in all humility I declined. In the end, however, by dextrous flattery of my vanity, soothingly applied in person by a member of the firm, I became so much puffed up with pride that I went so far as to sacrifice their interests by yielding to his solicitations. And blushingly I wrote that foreword.

Professor Biedl is doubtless quite right in his conviction that a translation of the original preface by Professor Richard Paltauf would have been of more interest to the English reader. That those responsible for the sale of the English edition should have been so benighted as to hold a contrary opinion is certainly not my fault. But then publishers, like translators, are curiously obstinate and wrong-headed people. To a grievous lack of all sense of propriety they add a lamentable ignorance of their own business. It is very deplorable. I am, Sir, yours faithfully,
Harley-street, W., April 18th, 1913. LEONARD WILLIAMS.

ABDOMINAL OBESITY AND ITS TREATMENT BY LOW-FREQUENCY OR LEDUC'S CURRENTS.

To the Editor of THE LANCET.

SIR,—In an article on the efficiency of the high-frequency currents combined with light baths in the treatment of obesity, which appeared in the *Annals of Electrobiology* in June, 1911, I remarked that obesity is more frequent in Egypt than elsewhere on account of climatic conditions and the sedentary and inactive lives of the upper classes. It is a very common spectacle in the streets of Cairo to see a number of men with extremely prominent abdomens, as large as, and even larger than, those of women in the later stages of childbearing, and for the most part the possessors of the bulk are proud of it, and if any remark is made on their appearance they answer that their stoutness is a sign of a strong constitution and flourishing health, and that nothing in the world would induce them to do anything to diminish it. But during the last few years, though very rarely, I have been consulted from time to time by corpulent patients concerning a treatment which would relieve their infirmity. I began first by applying vibratory massage, but was obliged to abandon it on account of the fatigue to which I exposed myself, as well as my assistant, before I had come to any conclusion as to its efficacy.

J. B., 45 years old, arthritis, neurotic, and for the past five years suffering from a dilated stomach, came to consult me on March 30th, 1911. The stomach could be traced below the umbilicus. The patient wanted to return to his home in Upper Egypt as quickly as possible, and could not follow a long treatment. I applied Leduc's currents with electrode cushions, as they are applied by Professor Doumer, at Lille. The length of each application was ten minutes, and the treatment was given daily except on Sundays. On the twelfth day, besides an amelioration of the stomach symptoms the patient had lost four kilogrammes, and his abdomen had so diminished in volume that his trousers were much too large.

Since then I have looked for the chance to put in practice in cases of obesity this method of treatment by current of feeble tension and perfect regularity, interrupted rhythmically and precisely. It seemed to me that it would be very efficacious.

My experiences, although not numerous enough to justify
any del
to me
follow t
further cases

1 G P, 28 years of age, corpulent, his abdominal girth being 1 10 metres (3 ft 8 in) came to consult me on August 1st, 1911 I applied low frequency currents at an intensity of 40 to 60 milliamperes, and obtained energetic contractions of the abdominal muscles without any unpleasant symptoms The treatment, which lasted 15 minutes, was given for the first six days consecutively, and afterwards repeated three times a week On the twelfth application the abdominal girth had diminished by 8 centimetres

2 A H 40 years old, corpulent, measuring 1 16 metres (3 ft 10½ in) in girth, began abdominal treatment by the Leduc's currents on August 8th, 1911 In ten succeeding days' treatment his abdominal perimeter diminished by 10 centimetres

3 M K, 55 years old, gouty, corpulent, weighing 105 kilos, with an abdominal perimeter of 1 2 metres (4 ft), began treatment by Leduc's currents on August 11th, 1911 At first he had ten uninterrupted applications, and afterwards received treatment three times a week On the twentieth application, which took place in the second week in September, 1911, his perimeter had been reduced by 12 centimetres —I am, Sir, yours faithfully,

Cairo, Jan 25th, 1913 Dr S C DAMOGIOU

VIVIPUNCTURE OR VIVISECTION?

To the Editor of THE LANCET

SIR,—Considering that all forms of experimental operation *upon the living animal are at present comprised* under the term vivisection and that the public makes no distinction between division of the tissues and simple injections, I venture to ask whether it would not be advisable to restrict the use of the word vivisection to the grosser operations and to introduce a new word for the slighter—which indeed constitute about 99 per cent of the whole I suggest the word *vivipuncture*, which is formed on the same lines as acupuncture It is true that the tables differentiate between the severe and the slight form, but the antivivisectionists do not, and it is important to hammer into the public mind that the vast *majority of experiments subject the animal only to* an operation which the human subject is always prepared to undergo himself, and indeed often demands

I am, Sir yours faithfully,

Ebury street S W, April 16th, 1913 RALPH W LEFTWICH

ROYAL MEDICAL BENEVOLENT FUND.

To the Editor of THE LANCET

SIR,—His Majesty the King was graciously pleased last year to confer on the Fund the title of "Royal" To celebrate this event it has been arranged to hold a dinner of those interested in the Fund and its Guild H R H Prince Arthur of Connaught, K G,
The dinner will take place
at the Hotel Cecil We h
complete success

It is not necessary to refer in detail to the work of the Fund, for this is fully set forth in the monthly reports of the cases relieved which you kindly publish in your journal The average *grants are at their best but small, yet, small as they* are, they are in many cases all that stand between the recipient and destitution The grants would be greater if the annual income from subscriptions and donations upon which they depend were increased Except for the working expenses, which are a little over 5 per cent, all that is received in the year from donations and subscriptions is expended upon the objects of charity, legacies being invested for the purpose of providing annuities The demands upon the Fund are heavy and constantly increasing Every little helps, and even small subscriptions are acceptable, for if every member of the profession subscribed only a few shillings a year the resources of the Fund would be largely increased, and much more could be done to relieve the poverty and distress than is at present possible

Though the Fund is mainly supported by members of the medical profession it has strong claims upon the general public also, for which the profession does so much with often a very inadequate return Medical men should therefore take advantage of every opportunity which might offer to press the claims of the Fund upon their grateful and well to do patients, who are often only too glad to know of a deserving charity which they can safely support

May we ask you to render another service to the Fund by publishing this letter

We are, Sir, yours faithfully,
JOHN TWEEDY, President
SAMUEL WEST, Hon Treasurer

Subscriptions and donations may be sent to the treasurer, Dr Samuel West 15, Wimpole street, London, W.

11 Chandos street, Cavendish square, W, April 23rd, 1913

QUIS CUSTODIET IPSOS CUSTODES?

To the Editor of THE LANCET

SIR,—I read with interest Dr J Walter Carr's letter in your issue of April 12th It would be interesting if he were to get his hospital colleague to make another blood examination under similar circumstances I have shown[1] that in patients affected with pulmonary tuberculosis there is a remarkable variation in the number of leucocytes from day to day, and even from hour to hour

A male patient aged 42, under Dr Hugh Walsham at the City of London Hospital for Diseases of the Chest, showed the following remarkable variation On the two days in question the patient—who had tuberculosis of upper lobe of both lungs—was kept strictly in bed, and his temperature was taken each time a leucocyte count was done

	Hour	Temperature	Leucocytes	
9/12/10	10 A M	97 1°	18 000	Right ear
	11 A M	98 1°	23 000	Left ear
	12 noon	98 1°	19 000	Right ear
	1 P M	98 1°	12 600	Left ear
	2 P M	98 5°	27 600	Right ear
	3 P M	93 5°	17 400	Left ear
	4 P M	98 2°	26 600	Right ear
	5 P M	98 5°	16 800	Left ear
			15 900	Right ear
	6 P M	98 5°	25 400	Right ear
			24 300	Left ear
	8 P M	98 0°	15 000	Left ear
			13 800	Right ear
	11 P M	96 8°	11 200	Left ear
			12 000	Right ear
10/12/10	8 A M	97 2°	11 600	
	10 A M	97 5°	12 200	
	11 A M	96 0°	14 500	
	12 noon	98 0°	13 000	
	1 P M	98 0°	18 500	
	2 P M	97 5°	15 200	
	4 P M	99 0°	19 000	

The blood was taken from the lobe of the ear, each ear being taken alternately but at 4 P M on 9/12/10 the leucocyte swing seemed to indicate inflammation of the right ear, so at 5 P M, 6 P M, 8 P M, and 11 P M counts were made from each ear, the one being a control for the other, yet the counts were the same from both ears, thus eliminating any fallacy due to inflammation

I am, Sir, yours faithfully,

Watford April 19th, 1913 THOMAS MARLIN, M D

A QUESTION IN LUNACY CERTIFICATION.

To the Editor of THE LANCET

SIR,—Will you allow me to point out that your correspondent Dr Robert Jones in THE LANCET of March 29th has mistaken my meaning, probably from careless reading he confuses the present and future tenses of the verb *to be* I took no exception to his statement "that reception orders signed by a justice not specially appointed *will be* invalid unless signed within 14 days by a justice so appointed" I simply pointed out that they *are* valid for a time, and that patients can be admitted on them and kept for 14 days, but I did not suggest that they could be detained longer unless the order were approved and signed by a judicial authority My desire was to point out to brother practitioners that private patients can be admitted on orders signed by any J.P., a knowledge of which fact may save them time and trouble.

---

[1] Journal of Clinical Research May, 1912.

In defence of magistrates who may not be aware that they are "specially appointed," I may say that in some counties, notably in Durham, all the county magistrates are *ipso facto* "specially appointed," and this being done *en bloc* they may not have their special responsibilities pointed out to them. I do not see that I have "failed to comprehend the interpretation of a valid order," or that I have "walked into a pitfall of the Lunacy Act."

I am, Sir, yours faithfully,
L. HARRIS-LISTON.

Middleton St. George, co. Durham, April 12th, 1913.

IODOFORM INJECTIONS IN PULMONARY TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—I have noticed the inconveniences referred to by Dr. Frank Crosbie and also minor ones which for obvious reasons I could not mention in a short letter. If petroleum is omitted from the injections they are not attended by paroxysms of coughing, except in those who are highly sensitive to ether.—I am, Sir, yours faithfully,

Bournemouth, April 19th, 1913. E. CURTIN.

NATIONAL MEDICAL UNION.

To the Editor of THE LANCET.

SIR,—A meeting of the executive committee of the National Medical Union was held at 5, John Dalton-street, Manchester, on April 16th. There was a large attendance, and an important discussion took place with regard to the present position under the National Insurance Act as it affects those practitioners who have not taken service. Numerous inquiries which have been made by doctors all over the country with regard to membership were reported. Many of these had written to say that they had retired from the panel, and others expressed their determination to do so at the first available opportunity. For example, 12 men from the Salford area alone have notified that, having removed their names from the lists, they wish to join the union. A Huddersfield member stated that he knew of two instances in his district of the non-acceptance of "sickness certificates" given by non-panel men. He was requested to lay full particulars before the committee at its next meeting, with a view to action being taken in the matter.

The honorary treasurer reported that the finances of the association were in a satisfactory condition. It was decided that a general meeting of the union should be held shortly, arrangements for which will be made at the next meeting of the committee. A subcommittee was appointed to deal with the organisation of the Union with a view to concerted action in the future.

I am, Sir, yours faithfully,
J. WEBSTER WATTS,
Secretary.

Manchester, April 22nd, 1913.

THE MEDICAL PROFESSION AND THE NATIONAL INSURANCE ACT.

To the Editor of THE LANCET.

SIR,—The following may be of interest to you. On April 1st a representative of the National Medical Guild had occasion to interview an official at the Insurance Commissioners' offices. The interview was arranged with regard to other matters, but in the course of conversation it transpired that the Commissioners were aware that certain Insurance Committees in the north of England were allowing "own arrangements" under the Insurance Act to be made with herbalists who had no sort of medical training. Allowing these arrangements means, of course, that the committees in question were prepared to pay for them.

On the same day a letter was sent from the National Medical Guild in which among other matters appeared the following sentence, viz.: "May I also state that I am informed that certain Insurance Committees in the north of England are permitting insured persons to make arrangements for medical treatment with herbalists and others not being medical men. May I ask whether this is legal, and if not, by whom and what action should be taken in the matter?" This letter was sent in order to obtain written verification of the fact.

On April 7th a reply was received from the Commissioners in which, again among other matter, appeared the sentence: "There is nothing in the National Insurance Act or the Regulations as to medical benefit which required that an insured person shall only be allowed to make his own arrangements for medical treatment and attendance on condition that these arrangements are made with a duly qualified medical practitioner."

On April 10th Sir J. D. Rees, M.P., asked a question in the House on the subject, which was as follows, viz: "Whether, under any section or subsection of the National Insurance Act or Regulations relating to such Act, the Commissioners will recognise and sanction the medical treatment of insured persons by unqualified individuals, such as herbalists and Christian Scientists; and, if so, whether, seeing that herbalists and other unqualified persons cannot administer anæsthetics, perform operations, treat fractures, or give death certificates, he will say why this class of treatment is recognised under the Regulations?"

Mr. Robertson replied for Mr. Masterman as follows (this is taken from the official Parliamentary report), viz.: "There is no provision in the regulations dealing specially with those cases, but, subject to the conditions therein prescribed, it is open to an Insurance Committee to allow insured persons to make their own arrangements instead of receiving medical attendance and treatment from a duly qualified medical practitioner on the panel."

Sir J. D. Rees then asked: "Can the honourable gentleman answer the question as regards the death certificates? How can Christian Scientists give certificates?"

Mr. Robertson replied: "It will rest with the Insurance Committee, if they are satisfied."

Putting the facts very shortly, they are as follows: We learnt from the Commissioners' Office that arrangements with "quacks" were being made. In reply to a letter they said there was nothing to prevent them being made. In the House of Commons they said the same.

We are, Sir, yours faithfully,
THE NATIONAL MEDICAL GUILD.

Villiers-street, Strand, W.C., April 14th, 1913.

To the Editor of THE LANCET

SIR,—Are members of the medical profession at last beginning to appreciate the unsoundness of the principles which underlie the insurance business in which they have allowed themselves to become partners? The capitation fee is none other than a premium to cover such attendance as an insured person may demand, when freed of more cost to himself; not simply what he actually requires because of illness or injury. There is no ruling that he may not clean his boots or weed his garden whilst demanding medical attendance.

A definite premium, payable in advance (usually annually), to cover a specified risk, is an integral condition of insurance as it is generally understood. We are forced to meet a portion of our risk first, and then receive a fractional part of our premium. And in case this is not sufficiently unbusinesslike, various fragments of this premium are to be sacrificed (ordinary mileage, &c.), and we are to be deprived of the remainder of the fee, when Providence has seen fit to remove certain of our patients during the year, if it happens before the last quarter. I am, Sir, yours faithfully,

WM. SPETTIGUE, M.B. Edin.

Wellington, Somerset, April 22nd, 1913.

To the Editor of THE LANCET.

SIR,—Your Special Commissioner on Medical Practice under the Insurance Act, in THE LANCET of April 5th, p. 989, quotes a remark of a Carlisle panel doctor which supports the gloomy prognoses as to the probable degrading effect of the Act on the scientific practice of medicine. The aforesaid practitioner congratulates himself on the fact that under the Act "we can treat the disease and not the people." Could anything more perniciously retrograde be conceived? Moreover, the Commissioners, who did not see their way to grant to the medical profession freedom from lay control because they were expending public money, and so were responsible for the way in which it was spent, now admit that this same public money may nevertheless be paid to herbalists and other quacks for "adequate medical treatment" such as the Act requires. Truly, beguiled by another Sinon, we *have accepted sacratâ arce a new monstrum infelix*, and even now—

> Inclusos utero Danaos et pinea furtim
> Laxat claustra Sinon.

I am, Sir, yours faithfully,

London, April 11th, 1913. PANTHUS.

THE GERMAN SURGICAL CONGRESS.

(FROM OUR BERLIN CORRESPONDENT.)

THE annual Congress of the German Surgical Association was held in Berlin from March 26th to 29th, Professor VON ANGERER presiding.

Tuberculosis of the Bones and Joints.

Professor GARRÉ (Bonn) gave a report of the definitive results of 2000 cases of tuberculosis of the joints treated by him during the past 19 years. He said that the choice between conservative treatment and the removal of the diseased parts by an operation depended partly on the seat of the affection and partly on the patient's age and social position. Tuberculous affections of the shoulder-joint were treated in the majority of cases by injections of iodoform, but in serious cases by resection according to Langenbeck's method. The cases treated conservatively became for the greater part ankylosed. The ultimate results of resection with regard to the restoration of function were better than *might have been expected, so that the indications for* resection should be extended. In the elbow-joint of children injection of iodoform and fixation were as a rule sufficient; in adults resection was preferable, the conservative treatment being less efficacious for such patients. Ankylosis followed resection in 50 per cent. of the cases. On the wrist-joint the results of conservative treatment were rather favourable. Resection should be avoided as much as possible; and when an operation became necessary only the affected parts should be removed. Coxitis ought generally *to be treated according to a conservative method* by plaster-of-Paris bandages, allowing the patient to walk, and by injections of iodoform into abscesses. In contractures a reduction must be tried, not forcibly, but by gradual extension. When the joint had then become painless a leather appliance was indicated; Hessing's splints had no special advantage. An attempt must be made to produce ankylosis. Resection should be reserved for cases in which no other procedure gave any ground for hope, because the results of resection were extremely unfavourable, one-third of the patients dying from tuberculosis, and only 50 per cent. of the remainder having a useful limb. In the knee-joint conservative treatment did not give a good result even in mild cases, for only 51 per cent. of the patients recovered, and most of them had an ankylosed joint; the results of resection were much better, as 92 per cent. recovered. In children resection was recommendable in *serious cases, because contraction was apt to follow ortho*pædic treatment. In the ankle-joint resection was performed in serious cases only, as conservative treatment generally gave good results. Abscesses were never opened by an incision but always by a puncture, and injections of iodoform were used. Radiotherapy had not been successful, because the rays were superficial in their action, and, moreover, exercised an injurious effect on the skin. Great attention must be given to general treatment, especially to life in the open air and to heliotherapy. Professor Garré made a reference to the brilliant results which had been obtained in Alpine climates, especially at Leysin, in Switzerland.

Dr. VULPIUS (Heidelberg) said that Alpine and seaside climates were not absolutely necessary for the successful treatment of tuberculosis, because fresh air and light could be obtained also elsewhere. He spoke in favour of special sanatoriums in which patients suffering from external tuberculosis could receive surgical treatment combined with physical and orthopædic remedial measures.

Dr. VON WRESZNIOWSKI (Czenstochau, in Russian Poland) explained his method of operation. He said that he made a wide opening so as to obtain access to the tuberculous focus; he then, after removal of all the affected parts of the bones and the soft tissues, plugged and fixed the joint. No sutures were inserted, so that at every change of dressing *the wound could be thoroughly examined and any new* foci of disease removed. The advantages of his operation were that the incisions healed up without the formation of fistulæ and that a useful limb remained; the drawback was the long duration of the treatment.

In the discussion Professor BIER (Berlin) recommended conservative treatment even in serious cases. He said that he avoided fixation, but used removable splints and passive congestion, and administered iodine internally in large doses. Under this treatment there was no formation of abscesses.

Professor DE QUERVAIN (Basle) said that he had seen excellent results in Alpine sanatoriums; the tuberculous lesions healed up without leaving fistulæ, and cicatrisation was rapid. In the Alpine sanatoriums operations were not often required.

Professor KÖNIG (Marburg) said that he had obtained good results by exposing the lesions to the rays of the mercury-quartz lamp, which might replace heliotherapy.

Professor WILMS (Heidelberg) said that Roentgen rays were efficacious, especially in affections of the upper extremity and of the glands. In patients giving a slight Pirquet reaction treatment by means of tuberculin was recommendable.

Dr. ISELIN (Basle) said that he had treated 367 patients by the Roentgen rays. Dry cases were less fit for this treatment than cases with profuse secretion. Spondylitis was a contra-indication, because deformity might arise from absorption, which was favoured by the X rays. Sometimes telangiectasia and ulceration developed even a year and a half after the Roentgen treatment.

Professor FRIEDRICH (Königsberg) warned surgeons against the too prolonged administration of iodine to children because of the damage which might be done to the ovaries and testes.

Duodenal Ulcer.

Professor KUTTNER (Breslau) said that he had collected 800 cases from his own clinical material and from that of other surgeons. The frequency of duodenal as compared with *gastric ulcer* was in the ratio of 3 to 5, but according to some authorities the ratio was more correctly stated as 1 to 3. The symptom of pain developing some time after taking food was not characteristic of the disease, as it might happen also in adhesions, cholelithiasis, ulcer of the stomach, and cancer of the stomach, and might be absent in duodenal ulcer. The presence of relapsing hyperacidity and intermitting motor insufficiency was of importance, and so were the results shown by Roentgen photographs. Some points of difference between gastric and duodenal ulcer were that in the latter the danger to life was greater, and there was less prospect of spontaneous recovery than in the former; at the same time, however, a development into cancer was less frequent in duodenal than in gastric ulcer. Internal treatment was of temporary effect only. Resection was not indicated unless cancer was suspected. Gastro-enterostomy with occlusion of the pylorus was the best treatment. Perforated ulcers must be operated upon as early as possible, and the perforation must be closed by the omentum; gastro-enterostomy must be performed at once when the condition of the patient allowed—otherwise it ought to be delayed until the subsidence of the urgent symptoms. Profuse acute hæmorrhage must be treated conservatively, but chronic hæmorrhage by operation.

Dr. VON DEN VELDEN (Düsseldorf) recommended for profuse acute hæmorrhage intravenous injections of hypertonic solutions of common salt. In chronic hæmorrhage gelatine injections were preferable.

Professor VON BERGMANN (Altona) drew attention to the connexion of duodenal ulcer with gastric neurosis. In 30 cases of ascertained duodenal ulcer local or general neurotic stigmata could be found, from which an affection of the visceral nerves could be inferred. The pains in duodenal ulcer were for the most part caused by spasm of the pylorus.

Dr. HAUDEK (Vienna) gave a description of the appearances fou [illegible] duodenal ulcer and said that [illegible] that the [illegible] gastric ul [illegible] of the diagnosis of duodenal ulcer; if clinically an ulcer was assumed, a normal finding made the presence of duodenal ulcer more likely than that of a gastric ulcer.

Dr. GUNDERMANN (Giessen) gave an account of attempts which he had made to produce ulcers in animals. By ligaturing the left branch of the portal vein he could produce in dogs numerous gastric ulcers, and in certain cases also duodenal ulcers. He considered that they were caused by toxic substances which in the normal liver cell were retained and destroyed, but were discharged when the liver cells were damaged. Ulcer of the stomach and the duodenum was, in his opinion, due to some imperfection in the function of the liver.

Professor FRIEDRICH drew attention to the connexion of diseases of the pancreas with those of the duodenum, a connexion which was observed in 6 out of 14 cases. In 3 of these cases cancer could be ascertained.

Professor SCHMIDT (Halle) said that in every case of hyperacidity it was necessary to look for an ulcer; there was a so-called "vicious circle" established between gastric ulcer and neurosis, the ulcer, however, being the primary symptom. Duodenal ulcer might heal up under internal treatment; it had been said that a healed duodenal ulcer was never seen in post-mortem examinations, but this did not prove anything, because the cicatrices were very difficult to find in the mucosa.

Cellulitis Attended with Evolution of Gas.

Professor MÜLLER (Rostock) reported a case in which resection of the knee-joint was followed by rapidly spreading gangrene attended with evolution of gas in the tissues and urgent toxic symptoms. He performed insufflation of oxygen into the subcutaneous tissue under high pressure, so that the skin from the knee upwards was inflated like a cushion. This was done three times within five days; on the tenth day an abscess formed in the gluteal region, and other abscesses followed, so that incisions became necessary, but the progress of the cellulitis was arrested after three insufflations and the severe clinical symptoms abated.

Treatment by Rhythmic Passive Congestion.

Dr. THIES (Giessen) recommended in the treatment of acute inflammation the use of passive congestion, established not in a continuous manner, according to Professor Bier's system, but in a rhythmical manner, so that between two congestions lasting for one or two minutes an interval of the same duration was interposed, and so on for as long as required. He had constructed an apparatus by which the rhythm could be regulated. The advantage of his method compared with permanent passive congestion was that it could be applied without interruption for many days, and that neither troublesome œdema nor pyrexia was produced.

Operations for Obstinate Constipation.

Dr. SCHMIEDEN (Berlin) said that in chronic constipation those cases were proper subjects for operation in which the seat and the cause could be ascertained. He gave clinical details of a case of extreme atony and dilatation of the colon with congenital extension of the mesentery. By Roentgen photography fæces were shown to be retained for days in the transverse colon. To remedy this condition he made a new passage by establishing a double anastomosis between the transverse colon and the bottom and the top of the sigmoid flexure.

(To be continued.)

PRESENTATIONS TO MEDICAL MEN.—At the Constitutional Club, Newton Abbot (Devon), on April 5th, Mr. Richard Henry Grimbly, M.R.C.S. Eng., L.S.A., was presented with a silver salver and soup tureen, suitably inscribed, as a mark of respect and esteem, on his relinquishing, after ten years' service, the chairmanship of the Mid-Devon Constitutional Club.—The members of the Bere Alston (Devon) parish council have presented Mr. Rowland Hill, M.R.C.S. Eng., with a framed illuminated address in recognition of his valuable services as chairman of the council for the past 12 years.—The members of the St. Breward men's branch of the Red Cross Society recently presented Mr. William Robert Newton Cole, M.D., M.Ch. R.U.I., of St. Tudy (Cornwall), with a silver mounted blotter, as a mark of appreciation for his services as lecturer to the class.

MEDICAL PRACTICE UNDER THE INSURANCE ACT.

(BY OUR SPECIAL COMMISSIONER.)

(Continued from p. 1128.)

VII.—GLASGOW ACQUIESCING IN THE ACT.

The New Terms Readily Approved.

GLASGOW, like Carlisle, was from the first considered a danger spot by those who were eager to "fight the Act" at all costs. The British Medical Association was warned by some of its best informed representatives in that city, when the capitation fee was increased, that anything like general resistance at Glasgow would be impossible. Certainly the majority of the medical profession at Glasgow were opposed to the Bill in its original form and voted steadily against working the Act, but on Dec. 17th, when the increased pay was offered, there was a very rapid change of front. All the points brought forward by the British Medical Association may not have been, in their view, conceded by the Government, but enough had been done to secure adherence.

Calling on a well-known practitioner in the West-end of Glasgow, who stood to lose, and indeed has lost, many private patients in consequence of the working of the Act, he nevertheless, and at once, expressed himself as fairly satisfied with the results up to date. The men, he said, who were still opposed to the Act were in many cases chiefly dissatisfied because they had not many insured persons on their list. Here there was a grievance, for while some had little to do, others were overworked to the detriment of science and at the risk of accidents due to strain and haste. The fact that at Glasgow there is a practitioner with about 4500 insured patients on his list was, both he and I considered, a very serious matter. The law, however, does not impose a limit, and it is difficult to see what can be done until the patients themselves complain, and this they do not seem in the mind to do. My informant went on to explain that he had joined the panel for the purpose of taking charge of his own patients only. If this were done universally many more practitioners would be reconciled to the working of the Act. He said that he relied on the stipulation that the allocation of other patients was to be carried out with due respect to arrangements made with the practitioners. Altogether he had now on his list about 1500 insured persons, and he was still keeping together a good private practice. This certainly meant an increase of work, but, he allowed, probably a larger income. There was, he found, a great increase of frivolous cases; many insured persons consulted him because they wanted a tonic, and one patient called because he was fearful lest he should be getting bald. On the other hand, 1500 persons, paying him 7*s.* a year each, would represent a larger sum than he used to obtain from this class of patient in fees. Thus, there was one family who had been his patients for 20 years. Some years none of them would be ill. Other years there might be a bill of £1, and at most £2. To-day five members are insured persons; and that meant a steady income of 35*s* a year, a much larger average than he ever received before.

The Improved Conditions of Contract Practice.

I have now in consideration a practitioner holding a high position in the local profession and established in one of the most fashionable parts of the city. It was natural that he should have very little contract practice in connexion with the old system of clubs and Friendly Societies. Under the Act, however, he has quite a large contract practice. This change was explained by the fact that, before the Act, if the medical officer of a club offended one member of a club he might lose the entire club; to-day he would only lose that one offended person. Then, again, if he was on friendly terms with the managers of a club he might offend individual members with less risk of dismissal. This was unfair to the patients. The Act, however, has placed the practitioner and the patient face to face. The patient can no longer threaten his medical attendant with the anger of the officers of his organisation, and the doctor can no longer shelter himself behind the friendliness of any of the managing committee of the club. Hence many medical men are now taking contract practice who previously had no such patients. The Act had simplified the relations between patient and doctor, said this informant; these were now strictly personal, and neither the one nor the other could secure the intervention of a club or the managing committee of a club. Nor could a patient in a moment of anger about what might prove to be an imaginary grievance dismiss his medical attendant. Time has to elapse and formalities have to be complied with before a change of medical attendant can be effected. *I think it will be allowed that during the interval* for reflection which procedure under the Act entails misapprehensions may be removed, irritation calm down, and a reconciliation happily effected. The change from contract practice for clubs and Friendly Societies to contract practice as a panel doctor under the Act is in this way a great improvement, and in some respects I think this more than any [illegible] the great claim of the Act to [illegible] practitioners who are used to [illegible] much opposition to the Act still prevails even among Glasgow practitioners. Many object to the idea of compulsion, and on professional grounds contract practice is also condemned. Many, at least in theory, continue to condemn compulsion and contract practice, but consider it right to sink their personal prejudices. I was told by another practitioner that many of his patients had expressed their satisfaction that he had rendered it easy for them to keep him as their medical adviser by joining the panel. And he pointed out that now he enjoyed the certainty of a fixed income, and could, in all sincerity, wish his patients good health, for it meant he would have less work and not less pay.

Why Resistance Failed.

Calling upon the secretary of the Local Medical Committee, I found he agreed that at first the medical profession at Glasgow were opposed to the Act, but he said that they rapidly changed their opinions when the better conditions were offered. The Medical Committee had been formed according to the Act to elect medical representatives on the Insurance Committee and to represent the medical men practising in the city as extended last November. The Greater Glasgow then created must have a population of about 900,000. Though probably more names appear on the register there are about 600 active practitioners. Of these, on March 14th 374 were on the panel and they had 203 panel chemists at their service. The number of insured persons was then 351,000—a good third of the entire population. Certain districts of Glasgow are densely populated by insured persons, but the panel doctors are not distributed according to this population; and, therefore, the panel doctors who happen to live in these crowded districts are more likely to be selected by the insured. This rendered it more difficult to secure unanimity in the ranks of the profession. It follows, of course, that the practitioner in a district where nearly all the inhabitants are insured persons will view the Act in a different light from those practitioners who live in residential suburbs where there are but few insured persons. To try to bring about a common agreement many meetings and discussions were held. The most important meeting was at Christmas, 1912, when the members of the West of Scotland Branch of the *British Medical Association* were convoked. This includes Ayrshire, Lanarkshire, and other counties. Some four to five hundred members attended, and opinions were so divided that a resolution to accept the new terms offered in regard to the Act was only carried by the casting vote of the chairman. The resolution did not approve of the Act, but said that as no satisfactory alternative was forthcoming it had better be accepted. The real weakness of the situation was due to the fact that only half of the members of the profession took part in this effort, and no one could tell what the absentees would do. But it was fairly well known that 80 or 90 practitioners were prepared to go on the panel, and this was in itself quite sufficient to render effective resistance impossible. A good deal of club contract practice existed on the East side of Glasgow, and obviously contract practice under the Act would be a great improvement. A large number of practitioners, attracted by the prospect—in fact, by the certainty of earning a larger income in a more pleasant manner—were sure to join the panel, and this would lead many others who were not quite so convinced as to the advantages. Hence the resistance to the Act became seriously weakened.

In Glasgow, of course, allowance was made by the m thoughtful members of the profession for the fact that there might be among the young and newly qualified medical men quite a number looking forward to whole-time appointments. This was for the latter a golden opportunity. Instead of painfully and patiently building up a practice, if they joined the panel and judiciously selected a district where there was most need of panel doctors, they might easily start life with a certainty of at least £300 and perhaps more in 7*s*. *capitation fees from insured persons.* Never before in the history of medicine has there been so brilliant a prospect for beginners as that offered by these circumstances. This must be allowed, even while we wonder what such bright commencements will proceed to or end in. Medical men who have grown grey in the slow process of building up a practice have been not a little shocked to see unknown youths jump into good incomes and extensive practices in the course of a few weeks. Such quick change feats go against every prudent instinct and engender forebodings as to the evil consequence that must ensue upon the wreckage of well established and well-tried precedents. In the meanwhile, practitioners who had but few private patients, and many club patients who only paid from 2*s*. 6*d*. a year to 4*s*. at most, are delighted to find that they have now 2000 and some even close upon 4000 insured persons on their list, each bringing in 7*s*. a year. They may grumble at the excessive amount of clerical work this has entailed, but those whose income has thus been doubled and more than doubled in the course of a few weeks can put up with some inconveniences.

As a further source of congratulation practitioners among the poor are getting paid now for work that had never before been remunerated. At Greenock, notably, I heard of three medical practitioners who never expected to receive more than 50 per cent. of the very modest fees they charged their *patients. Now that the entire population from which such* patients were drawn are paying 7*s*. a head, their medical attendants are able to afford motor-cars.

The Poorest Pay for the Best Work.

Nevertheless, and in spite of these golden stories, there is the other side. Wages are rising, trade is just now very brisk; and on the Clyde they are building the largest ships in the world. When there is a shortage of money, will the Act work as easily? There are to-day many able practitioners on the Glasgow panel who have but few insured persons on their list. This is due to the fact that they have no consulting room or surgery in a neighbourhood where panel patients particularly live. Also, however high the standing of a medical practitioner may be, it is possible that his reputation is not widely spread among the class of persons likely to be insured. Many doctors with a middle-class practice have suffered. The sons and daughters of well-*to-do parents* may be earning, as clerks and typewriters, £1 or £2 a week. When they fell ill, their parents paid full fees for medical attendance, but now they are insured persons. [illegible] ts, their family physician [illegible] at the children of well-to-[illegible] They expect just about the same careful attendance they had before when their parents paid full fees for them, and they are not numerous enough to ensure a good income for their medical attendant. Here a good class of medical practice is receiving very poor pay. To treat a patient as club patients used to be treated pays well, and the poorest sections of the community have not been accustomed to more elaborate treatment. *But patients for whom the parents used to pay* 3*s*. 6*d*. or even 5*s*. a visit are not to be so easily satisfied. Their medical attendants must avoid the appearance of giving rough-and-ready treatment, which may be at bottom every whit as good as any supplied with greater observance *of ceremony*, lest they should get a bad name and so lose *patients* (the parents, for example) who are not insured and continue paying full fees. Thus, it will be seen that the better-class practice may well be the worst paid.

A Serious Danger.

On the other hand, so abundant is the remuneration in comparison with the trouble taken in attending to the poorest sections of the community that one *medical man in* Glasgow is giving up a large private practice because he finds practice under the National Insurance Act pays so much better. This panel doctor's list is so long that he is credited with having one birth per day. There is obviously in this a very great danger. Some measure should at once be enforced to prevent the creation of a vested interest in lists that are too long for efficient service. This I brought prominently to the notice of the secretary of the Medical Committee and the secretary of the Insurance Committee. Both readily recognised the evil, admitted its existence in Glasgow, and the risks to public health it entails. The secretary of the Medical Committee thought that to limit the lists more experience must be acquired. There must be clear evidence that the work is not done properly. Then what was too much for one man was barely enough for another, the personal factor counting for so much in the management of a practice. In a congested area, again, many more visits can be paid than in a widespread district with but little increase of trouble or outlay. The secretary of the Insurance Committee, on his side, hoped things would find their proper level by reason of the complaints that would be made. There would be inquests, and investigations, and scandals, and the panel doctors would exercise pressure upon each other. The patients on their side would also help by withdrawing their names from overburdened lists To this I naturally objected that, in the meanwhile, vested interests would have been created; and however just the cause of complaint it was always extremely difficult to remove a vested interest. In any case there was not a likelihood of many complaints. The poorest, the most forlorn sections of the community, those who have the best cause for complaining, were often lacking in the courage or capacity to take action, particularly if the complaint had to be made in a formal manner and in writing. Is it necessary to wait till several preventable deaths have occurred before attempting to check what, on all hands, is recognised to be a danger and an evil? Some exceptions could be made while matters were adjusting themselves; but it might at once be proclaimed that no panel doctor will be allowed to permanently keep on his list more than, for instance, 2000 names unless he can show that he has good claims for being able to organise his services to the real advantage of a larger number.

(*To be continued.*)

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Rise in Price of Food in Relation to Wages.

THE *Manchester Guardian* has made some interesting inquiries as to the rise in the price of staple articles of food in recent years. It is contended by some writers that though nominal wages are higher the purchasing power of wages has actually declined. The prices stated below are the prices at the port, and 25 per cent. or thereabouts must be added to cover the additional costs. I may tabulate a few items:—

Per lb.	1906.	1912.
Bacon	6·64*d.*	7·21*d.*
Butter	12·82*d.*	13·95*d.*
Cheese	6·55*d.*	7·47*d.*
Flour	1·09*d.*	1·24*d.*
Lard...	4·89*d.*	5·77*d.*
Meal...	1·18*d.*	1·44*d.*
Sugar	1·83*d.*	2·08*d.*
Tea	15·42*d.*	15·85*d.*

The duty on sugar was reduced in 1908 from 4*s.* 2*d.* per cwt. to 1*s.* 10*d.*, and that on tea from 6*d.* to 5*d.* per pound last year. During the last six years the round increase is 10·4 per cent., and the same result is obtained if 25 per cent. is added to get the retail prices. Thus, 22*s.* must be paid for what would have cost only £1 six years ago. If the period of comparison is carried back to 1898 the increase is 16·33 per cent. Potatoes have gone up fully 50 per cent. The price of fish has also greatly increased, while as to English meat the rise in price is reckoned as from 10 to 15 per cent. The average price of coal at the pit mouth has risen in the same period from 10*s.* 9*d.* a ton to 14*s.* 9*d.*, an increase of 37 per cent. As to wages in Lancashire, in many occupations—clerical workers, warehousemen—the great mass of unorganised labourers—the increase, if any, has been only trifling. In the cotton trade an advance of 5 per cent. was given to cardroom operators in June, 1907. The average wages for men are from 29*s.* to 34*s.*, for women from 19*s.* to 28*s.*, and for girls from 9*s.* to 13*s.* Weavers earn from 24*s.* to 33*s.* per week. Carpenters a year ago obtained an increase from 9½*d.* to 10*d.* per hour. The position of organised carters has been improved, for they now have a minimum wage of 25*s.* It is clear that it is more difficult to-day for workers to maintain the same standard of living as five or six years ago.

Infantile Mortality and Women Workers in Mills and Factories.

A survey of the courts and alleys of Warrington by members of the Health Week Association has demonstrated the success attending the provision of more light and air and a purer atmosphere by the local authorities. Dr. J. C. Hibbert, the medical officer of health, in a lecture urged the people to coöperate with the authorities in procuring for themselves the safeguards of modern sanitation. Mr. P. M. Oliver, speaking of the heavy infantile mortality, stated that at Burnley 60 per cent. of the married women under 35 years of age worked at occupations away from their homes, and 20 per cent. of their children died before they were one year old. At Bury 45 per cent. worked away from their homes, and 16 per cent. of their children died during their first year. In Burton, where the percentage of women employed was only 2, the infantile mortality in the first year was 12 per cent. Mr. Oliver concluded: "You send the woman to the mill and you send the child to the grave." From recent investigations it would appear that about 70 per cent. of the infantile mortality is caused by (1) unsatisfactory feeding, (2) mismanagement and exposure, and (3) defective physique of the mother—to each of which causes the daily absence from home is contributory. These conclusions confirm Dr. Reid's 20 years' investigations in the potteries.

The Sanitary Condition of the Hayfield District.

In his final report before retiring Mr. C. J. Bennet, of Buxton, for nearly 40 years medical officer of health for the Hayfield district, says that in the district, which should be one of the healthiest in England, scarlet fever and diphtheria are endemic, while one person in every 100 houses is suffering from tuberculosis. He impresses on the authorities the terrible waste in money, life, and economic efficiency thus entailed.

Insurance Act Abuses.

In the Hyde district it is stated that there is considerable abuse of the Insurance Act by women mill-workers. Many seem to think that so long as they get a doctor's certificate they can do anything except go to the mill. Some do their own washing, baking, and general housekeeping; some go to picture palaces when they are reported "sick" and are drawing sick pay. Against 2½ per cent. of male members drawing insurance money, the percentage of female workers is between 5 and 6. In the Accrington district, while there have been abuses of the Act, the number of cases is small, probably because immediately the Act came into operation the District Weavers' Association appointed a sick visitor and a sick steward, whose work it is to go round daily, at any hour, paying surprise visits to those in receipt of sick pay, by way of showing what those on the sick list cannot do under the Act.

April 22nd.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The late Mr. Jordan Lloyd.

AT a special meeting of the general committee of the Queen's Hospital the following resolution was passed:

> That the General Committee of the Queen's Hospital record with the deepest sorrow the sudden and untimely death of Mr. Jordan Lloyd, who since 1879 has been closely associated with the work of the institution, first as house surgeon, 1879, then as casualty surgeon, 1881, and as honorary surgeon from 1883 until his death. They gratefully recall his devotion to his duties, and his unfailing kindness to all with whom he came in contact. By the death of a surgeon of such eminence, skill, and distinguished reputation, the public, the hospital, and the medical profession suffer a grievous loss. The committee desire to tender to Mrs. Jordan Lloyd and the members of her family their most sincere and heartfelt sympathy.

A subcommittee was appointed to consider how the services of the late Mr. Jordan Lloyd may be perpetuated.

Birmingham Health Week.

Two mass meetings will be held in the town hall on April 28th and 29th, at which the Bishop of Birmingham, Dr John Robertson, the medical officer of health, and Professor H Gilbert Barling, the Vice Chancellor of the University, will speak A large number of clergymen and ministers have promised to preach health sermons on the Sunday, and addresses will be given in over 60 adult schools and P S A 's on the same day Lectures will be given at each of the branches of the General Dispensary The baths committee has arranged for special exhibitions of swimming and life saving in the city baths during the week Many other meetings in various places are also arranged

April 22nd

BRISTOL AND WESTERN COUNTIES

(FROM OUR OWN CORRESPONDENTS)

Bristol and Sanatorium Treatment

THE health committee has adopted a scheme for the treatment of tuberculosis on a civic basis, and has sent it to the Insurance Committee for consideration before submitting it finally to the city council It is proposed to establish two dispensaries, one in Portland square and the other in Redcliffe Parade (this dispensary has already been at work for over a year on a voluntary basis) As to sanatoriums, to the 21 beds already available for Bristol cases at Winsley 29 more are to be added, while three new blocks of 20 beds each are being built at Ham Green These latter will include accommodation for advanced and after-care cases The estimated annual cost per bed is £78 at Winsley and £69 14*s* at Ham Green The health committee is prepared to appropriate 55 beds, 40 of them at Winsley, for insured persons The medical staff will consist of 1 A tuberculosis officer to control the clinical work of the dispensaries, to act as expert clinical adviser to the Insurance Committee, and as consulting officer for purposes of domiciliary treatment , salary £400, rising by £50 a year to £500 2 A resident medical officer at Ham Green , salary £300, rising by £50 a year to £400, with board and lodging, less any sum received for the treatment of insured persons 3 An assistant medical officer to live at Ham Green, and to help both in sanatorium and dispensary work , salary £200 rising to £250 The whole scheme will be administered by a consultative committee, consisting of six members of the health committee, four of the Insurance Committee, and two of the Civic League Practically the whole of this scheme has already received the approval of the Insurance Committee

Bristol Eye Dispensary

The report for 1912 which was presented at the annual meeting of this institution, contained several items of interest The number of new out patients seen during the year was 3309, a considerable increase on previous years Owing to the large increase in refraction work falling on the staff as a direct consequence of the medical inspection of school children, it has been found necessary to refuse to undertake the ordering of spectacles for patients coming to the dispensary as a result of school inspection Mr P J Worsley has resigned the chairmanship an office which he has filled with conspicuous success for nearly 20 years Mr E H E Stack also has resigned his surgeonship which was filled by the promotion of the senior assistant surgeon, Mr A Fells

The Insurance Medical Service in Bristol

The opening of the second quarter of the operation of the medical benefit organisation of the Insurance Act finds almost 10 000 persons who have neglected to choose a doctor for themselves, these, unless they make haste will be assigned to panel practitioners by the Insurance Committee The number of panel practitioners will not alter materially , several have resigned, but their places will be filled by others who had not heretofore joined the service

The Decrease of Vaccination in the West of England

At a recent meeting of the Warmley (Gloucestershire) board of guardians the chairman said that the whole system of vaccination was in a wretched state The clerk added that the more the vaccination officers worried people with unvaccinated children, the greater were the number of exemptions granted The diminution of vaccination in the West of England is undoubtedly serious

Increase of Salary for Medical Officer of Health

At a meeting of the Somerset county council held last week it was decided, on the recommendation of the public health and housing committee, to increase the salary of the medical officer of health by the sum of £100 per annum

Death of Mr George Alfred Harrison, L R C P Lond , M R C S Eng

Mr G A Harrison, who died recently in his forty seventh year at Eltham, New Zealand, from blood poisoning contracted in the performance of his professional duties, was the son of Dr A J Harrison, consulting physician to the Bristol General Hospital He was educated at Clifton College, Pembroke College, Cambridge, and St Bartholomew s Hospital He took the Conjoint qualifications of London in 1893 Mr Harrison had been in practice for several years at Eltham, where he was highly esteemed He leaves a widow and two sons

LIVERPOOL

(FROM OUR OWN CORRESPONDENT)

Liverpool Scheme for a Proposed Sanatorium for Tuberculosis

As the outcome of a deliberation at a special meeting of the port sanitary and hospitals committee of the Liverpool corporation it was decided to ask the city council to allow the committee to advertise for competitive designs for a sanatorium for tuberculous patients, and to offer three premiums—viz , first £150 , second, £100 , and third, £50 The committee considered all aspects of the question, and was unanimous in its recommendation, which will come up for consideration at the next meeting of the council The sanatorium proposed to be erected will be altogether separate from the present hospital at Fazakerley, and will provide accommodation for 250 patients The cost of the building will be partly borne out of the grant provided for in the Budget of 1911 The committee s expectation is that the amount forthcoming from this source will be approximately two thirds of the total The need for the sanatorium is very urgent and the committee hopes that the scheme will pass the council without opposition so that the work of construction will proceed with the least possible delay —Dr W C Oram has been appointed by the education authority to the charge of the new clinic for X ray treatment of ringworm

Liverpool Royal Infirmary and its Need of Radium

The need for a supply of radium for use in cancer cases has long been felt by the director of the electrical department at the Royal Infirmary It is with pleasure that I am able to record that the matter has been taken in hand by the proprietors of the *Liverpool Daily Post and Mercury* A leading article appeared a few days ago in the columns of that newspaper appealing to the generosity of the Liverpool public for contributions towards a supply of radium with the object of the appeal e publication of the article It will enable the committee to purchase the necessary quantity £800 have already been promised, and it is hoped that in a few days the whole amount will be forthcoming

Changes in the Honorary Staff of the David Lewis Northern Hospital

At a meeting of the election committee held on April 16th Dr John Owen honorary assistant physician, was elected honorary physician , and Mr George C F Simpson honorary assistant surgeon, was elected honorary surgeon Dr Owen takes the place of Dr W B Warrington, who has joined the honorary staff of the Liverpool Royal Infirmary, while Mr Simpson succeeds Mr Damer Harrisson whose term of office has expired

Liverpool Medical Institution

At the last ordinary meeting of the session the president, Mr Robert Jones, proposed "that the congratulations of the members of this society be tendered to Dr William Blair Bell on the occasion of the Hunterian medal having been awarded to him by the Royal College of Surgeons, England." The proposition was carried with acclamation

WALES.

(FROM OUR OWN CORRESPONDENT.)

Diminishing Entries to the University of Wales.

CONCERN is being expressed in certain quarters at the falling off in the number of candidates who enter for the matriculation examination of the University of Wales. In 1908 there were 867 entries, and in 1912 only 408. Various explanations have been put forward to account for this reduction, though possibly it is due to more than one cause. The fees for the Welsh examination are a little higher than those at the Scottish universities and at some of the English universities, but it is hardly likely that this has an appreciable influence on candidates in their choice, and it is contended that the high percentage of failures indicates a more difficult examination than elsewhere, though this fact cannot wholly account for the great drop in the number of entrants. The most probable explanation is that owing to the large number of graduates who have left the University in former years it is found that the possession of a degree is not of so much assistance as it formerly was in obtaining lucrative positions, and that young men are finding they can spend the years which would be given to their university life to better purpose in commercial careers.

Retirement of Dr. H. R. Vachell from the Cardiff Hospital.

Under one of the general rules of the King Edward VII. Hospital, Cardiff, requiring the retirement of members of the medical staff at the age of 65 years, Dr. Herbert R. Vachell has resigned his position of senior honorary physician. Dr. Vachell was first associated with the hospital as long ago as 1877, when he was elected house surgeon, an appointment which he held for three years. From 1885 until 1895 he was out-patient medical officer, and in the latter year was elected an assistant physician, becoming full physician in 1902. Some idea of the development of the hospital during the 36 years in which Dr. Vachell has been officially connected with it may be gathered from the statement that in 1877 the number of in-patients treated was 493, and the number of out-patients 4918, while last year these numbers were multiplied by five. The income, which was under £3000 in 1877, is now five times that amount. At the meeting of the board of management at which Dr. Vachell's resignation was tendered, tribute was paid to the zealous, conscientious, and able manner in which he had carried out his duties as a member of the medical staff during the whole of the lengthy period of his connexion with the hospital.

Insanitary British Ships.

In his annual report to the Newport (Mon.) port sanitary authority the medical officer of health, Dr. J. Howard-Jones, once again draws attention to the inadequacy of the sanitary supervision of British ships by the Board of Trade. In two newly launched vessels which arrived at Newport from the north the crew's spaces contravened the regulations of the Board, although both of them had been certified as satisfactory. During 1912 there entered the port of Newport 1809 "coastwise" vessels, and no fewer than 281, or 15·5 per cent., were found to be insanitary in some respects, the percentage of steamships being double that of sailing ships. The suggestions in the report are that regulations should be made for ensuring a higher standard of hygiene on the part both of masters and members of the crew; that there should be an increase in the staff of Board of Trade marine surveyors in order that the regulations of the Board might be efficiently enforced; and that as the accommodation provided on many new vessels is very unsatisfactory and antiquated greater attention should be given to the elementary principles of domestic hygiene in the designing of the crews' spaces on new vessels. Dr. Howard-Jones again urges the desirability of appointing an inter-departmental committee of the Board of Trade and Local Government Board for considering the whole question of the hygiene of the merchant service. Among the diseases to which sailors are peculiarly liable he includes those associated with the peculiar environment of seamen, such as damp forecastles, contaminated water-supplies, and the close association of the sick with the healthy in the confined quarters on shipboard. It is against these diseases that the efforts of the port sanitary authority for improving the sanitation of vessels should be directed, more especially having regard to faulty construction, wear and tear, lack of cleanliness, and forms of nuisance generally on board.

April 22nd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

National Health Week.

IN many parts of the country last week was observed as the National Health Week. The object of the movement is to arouse an intelligent interest in health even among the most thoughtless and ignorant members of the community, and to secure increased support for the local health authorities and voluntary societies. One of the latest towns to take it up in Scotland is Wishaw, and a start was made in the beginning of the week, when special sermons were preached in most of the churches on Sunday. During the week the children in the schools had short and simple addresses given to them; cookery demonstrations were given each evening at suitable centres, where exhibitions of gas fires, cookers, &c., also took place; the local cinematograph halls showed in the afternoons instructive films illustrative of some appropriate health topic; and suitable literature was distributed throughout the burgh by the Boy Scouts. The movement was largely supported, and prominent public men interested themselves by presiding at the various gatherings.

The Kirkcaldy Small-pox Outbreak.

Dr. G. W. McIntosh, medical officer of health of Kirkcaldy burgh, has just issued an interesting report on the recent small-pox outbreak, which occurred about the end of September last and was responsible for 42 cases before the end of the year. As no case of small-pox was known of in Scotland about the time the outbreak occurred, Dr. McIntosh was forced to the conclusion that the flax at the spinning mill, among which the boy who first contracted the disease worked, was most likely to have borne the infection to him. During the outbreak free vaccination was offered, and medical practitioners vaccinated 6395 persons at a cost of £639 10*s.* to the town. In addition to this number, 500 were vaccinated by Dr. McIntosh, and 300 at their own expense, giving a total of at least 7195, thus showing that more than one-sixth of the entire population had been recently vaccinated. Had this outbreak of small-pox been delayed another five years a large number of unvaccinated children, exempted through the loophole of the conscientious objection clause, would have been attending the schools, and the consequences might have been appalling.

Vaccination at Buckie.

The local medical officer reported to the Buckie town council last week that something like three-fourths of the population of the burgh would be unvaccinated shortly through conscientious objections.

A New Whole-time Appointment in Orkney.

At a meeting of the secondary education committee for the county of Orkney at Kirkwall last week Dr. R. P. Heddle was appointed medical officer for Orkney under the scheme for the inspection of school children. By arrangement with the county council it is proposed that Dr. Heddle will retain his appointment as medical officer of health for the county, but he will relinquish his private practice and devote his whole attention to the duties of public health and medical inspection of school children.

The National Insurance Act at Work.

Interesting figures have lately been published regarding the working of the Act in the rural parish of Strichen, through the local secretaries of the Free Gardeners Society and of the Strichen branch of the Farm Servants Union. No attempt to make deductions from the limited numbers is made, but the facts are interesting as being probably typical of other rural parishes in the north-east of Scotland. The great majority of the employees in the district are insured with these two societies. The former has 250 of both sexes and of all classes of workers on its books, and the latter has 94 of both sexes, all farm workers, making a total of 344 insured persons. The Free Gardeners administered sickness benefit during the quarter to 18 State insured members, 13 men and 5 women, the men receiving a total of £11 5*s.* 2*d.*, and the women a total of £3 15*s.* Each male got an average of 17*s.* 3*d.*, and each female an average of 15*s.*; the average for both sexes combined works out at 16*s.* 8*d.* each. This is equal to a return of about 1*s.* 2*d.* to each of the total insured persons, the males receiving about 1*d.* more each than the females. Six cases of maternity benefit were paid £9. There are in addition the medical benefit and drugs; but no attempt has been made to set down the value of medical attendance or consultation and drugs in figures dealing with one quarter. The length of sickness among the 13 males ranged from 4 to 39 days, and totalled 170 days; the loss among all insured males amounted to a fraction less than one day, while the loss among all insured females amounted to slightly more than one day. Roughly speaking, 9 per cent. of male farm servants were in receipt of sickness benefit, as compared with 4 per cent. of all other males; 8 per cent. of female farm workers were in receipt of sickness benefit, as compared with 7 per cent. among all other female servants. With regard to the figures shown by the Farm Servants Union, with its 86 men and 8 women, all farm workers, none of the females received sickness benefit. Five of the men obtained an average of 9*s.* 10*d.* each, as compared with the 17*s.* 3*d.* of the Free Gardeners. Each of the 94 members had returned to him or her, therefore, about 6*d.* on an average, as compared with the 1*s.* 2*d.* among the gardeners. Maternity benefit was given in two cases.

April 22nd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Medical Certification under the National Insurance Act.

A MEETING of the Advisory Committee to the Irish Insurance Commission was held on April 15th, when the chairman, Mr. P. D. Glynn, made a detailed statement concerning the reception of the scheme for medical certification put forward by the Commissioners. Up to the previous day the Commissioners had received the names of 610 doctors to act on the panels. *Of these, 14 had afterwards withdrawn.* It would appear from Mr. Glynn's statement that panels have been constituted in about one-third of the country. In a few of the areas—e.g., Belfast, Antrim, Armagh, and Donegal—the panels seem to be adequate. In other areas, as in Clare and Mayo, the panels, though declared "complete," are certainly inadequate. The Advisory Committee discussed the matter in private, and resolutions were carried that in areas where the panels have failed to fill the Commissioners, after consultation with the Approved Societies and Insurance Com- [illegible] paid *per capita* in accordance with the number of members of these societies in those areas covered by the first part of the resolution. The Commissioners are therefore convening, in each of the areas referred to, conferences between representatives of the Insurance Committees and the Approved Societies.

Women's National Health Association.

At the annual meeting of the general council of the Women's National Health Association held last week in Dublin, Lady Aberdeen said that there were 19,000 members and 151 branches. Eleven branches had been dissolved, but 11 new ones had been formed. The annual subscriptions amounted to £994 9*s.* 11*d.* In addition the branches had raised approximately £4000. The association had been entrusted with a Government grant for providing sanatorium accommodation for patients under the National Insurance Act. Between 80 and 90 schools were receiving meals from bra[illegible] A number of branches were [illegible] couraging agricultural and [illegible] special report of the Collier Memorial Dispensary would give an idea of what might be done by those dispensaries when they were fully established. 1700 patients had been registered at the dispensary, and 4831 persons had been brought under the influence of tuberculosis nurses. The dispensary having been transferred to the corporation of Dublin, the balance of the Collier donation would be applied towards the erection of a pavilion at the Peamount Sanatorium. A resolution was passed asking the Government to strengthen the existing laws dealing with the disinfection, and, in proper cases, the destruction of infected dwellings.

Vacancy on the Council of the Royal College of Surgeons.

There is a hot canvass for the vacancy on the council of the Royal College of Surgeons, created by the death of Sir Henry Swanzy. Several Dublin practitioners are candidates, while, on the other hand, a memorial has been widely and influentially signed urging the election of a country Fellow. The unexpired term of office is brief.

The Extension of Medical Benefit to Ireland.

At a meeting in Dublin, on April 18th, of the Irish County Councils' General Council, a resolution of the executive committee that medical benefit under the National Insurance Act should not be extended to Ireland—except the urban centres—unless accompanied by a revision of the Poor-law medical system, was adopted. This resolution, taken in conjunction with the declaration of the actuary to the Insurance Commissioners that extension to the county boroughs and not to the rest of the country is "actuarially impossible," appears to render unlikely the proposed project of extending medical benefits to Ireland. A conference will assemble in London on April 30th to consider the question.

The Final Census Returns for Ireland.

A Parliamentary Blue-book of over 600 pages, just issued, gives the corrected figures of the lately taken Census of Ireland. The total population of Ireland, which in 1901 showed a total of 4,458,775, is now (1911) 4,390,212, indicating a loss in the decennium of 68,556, or 1·5 per cent. One in every 57 of the population is returned in 1911 (as compared with 1 in 44 of 1901) as receiving Poor-law relief. The number of emigrants during the ten years ending March 31st, 1911, amounted to 345,159 (171,875 males and 173,284 females), which is a smaller number than in either of the two preceding ten-year periods. There are only three cities in Ireland with populations over 50,000—viz., Belfast, 386,947; Dublin, 304,802; and Cork, 76,675. During the ten years 1901–11, the population of Belfast has increased by 37,767, that of Dublin by 14,164, and that of Cork by 551.

Irish Emigration in 1912.

During 1912 there were 29,79[illegible] a decrease of 1229 as compared [illegible] below the average for any year [illegible] for which records are available. Of the emigrants, 6·9 per 1000 were from Munster, 7·5 from Ulster, 10·6 from Connaught, and 3·3 from Leinster. Over 20,000 went to the United States and nearly 6000 to Canada. Since May 1st, 1851 (*when statistics of emigration were first begun*), 4,247,360 Irish people have emigrated, and of these 2,207,637 were males. This number represents 81·4 per cent. of the average population of Ireland, Munster's contribution to the total equalling 109·9 per cent. of her average population, Connaught's 89·7 per cent., Ulster's 69·2 per cent., and Leinster's 55 per cent. Roughly, two-thirds of last year's emigrants were between 15 and 25 years of age, and one-quarter were between 25 and 35—that is, it is the very *flower of the people who are emigrating.*

Londonderry Doctors and the Friendly Societies.

Owing to the failure of the Federation of Londonderry *Benefit Societies to arrange terms* with the local doctors, it was decided on April 7th to import to that city a number of medical men who had applied for appointments. This dispute has gone on since the doctors resigned their contract appointments with Friendly Societies in January last.

Death of John McGee MacCormac, M.D. Durh.

Dr. John McGee MacCormac, of Belfast, dropped dead suddenly from heart disease on April 20th while out walking. Dr. MacCormac was born at Ballynahinch, co. Down. He was educated [illegible] Queen's Colleg[illegible] of the Royal C[illegible] After practisin[illegible] attended the London hospitals. In 1885 he became M.D. of Durham. Returning to Belfast, he *established a considerable* practice in nervous diseases in the North of Ireland, and in 1896 he founded the Hospital for Nervous Diseases, of which he was honorary physician at the time of his death. He was a Fellow of the Royal Society of Medicine and a member of the Neurological Society of London. He wrote considerably on nervous diseases in the medical journals, some of the articles appearing in THE LANCET. He is survived by his widow and by one daughter, who is married to Dr. J. B. Lendrum, of Oldham.

April 22nd.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Professor Landouzy.

ON April 14th Professor Landouzy, doyen of the Faculty of Medicine of Paris, was elected, by 42 out of 55 votes, a free associate Member of the Académie des Sciences.

Lesions of the Semilunar Cartilages.

M. Quénu, the eminent surgeon, recently said at the Société de Chirurgie that he had had to deal with three cases of lesions of the semilunar cartilages of the knee. Unfortunately, he had been unable to trace one of the cases, but one of the other two was that of a man, 26 years of age, who in 1890 had had pain and swelling of the knee following on a fall. These symptoms rapidly improved and disappeared after eight days of rest and treatment by massage. From time to time, however, he suffered from hydrarthrosis, also from a sudden stoppage of flexion of the limb during walking, accompanied by a jumping sensation (*sensation de ressort*). When M. Quénu again saw this patient, seven years after the accident, he found on the inner aspect of the knee at the interarticular level an elongated projection, which became displaced during the movements of the joint. On making an incision it was found that the anterior cornu of the semilunar cartilage was torn, and that the cartilage was twisted outwards upon itself. Partial resection brought about a cure. The other case was that of a man, 22 years of age, who after a fall was unable to flex the leg completely. One day when seated he found himself unable to rise unaided, which led him to consult the speaker. He had a slight swelling of the knee, and on its inner aspect a painful projection was found. Movement of the leg caused pain, and complete extension was impossible. M. Quénu diagnosed a tear of the internal cartilage, part of it being reflected upon the rest. The name of traumatism of the semilunar cartilage, he said, seemed admirably suited to this class of injuries, which occurred in displacements, luxations, or fractures. When inflammation existed it was only secondary. The diagnosis of this condition could be made, without regard to the more or less recent date of the accident, by the impossibility of extending the leg and the habitual absence of hæmarthrosis. Radiography failed usually to afford any precise information. The injury could be distinguished from foreign bodies by the seat of the pain, which in the latter was not fixed, by swelling at the interarticular line and by the presence or absence of intra-articular effusion. As to simple inflammation of the meniscus, M. Quénu considered it open to doubt. Roux claimed to have seen frequent examples of it, but the absence of any anatomical verification discounted the precise value of the observations. As to treatment, Lejars and Jacob, agreeing with Bergmann, advised total resection of the cartilage. If only one end was detached M. Quénu considered partial resection sufficient, and his two patients treated in that way were both cured. If a fissure or a fracture coexisted total resection of the cartilage was necessary. In certain cases fixation might suffice.

The Treatment of Hæmoptysis.

On April 11th, at the Société Médicale des Hôpitaux, communications were made by various authors concerning the treatment of hæmoptysis in the tuberculous. M. Rist recommended the use of intravenous injections of an extract of the posterior lobe of the hypophysis. M. Sergent said that he had obtained the best results from ipecacuanha powder in small doses, combined with small amounts of opium. M. Flandin reported a case of profuse hæmoptysis checked on the day of its occurrence by a subcutaneous injection of 4 centigrammes of emetine hydrochlorate.

A Provident Association for French Medical Men.

A mutual aid society for the women and children of medical men has been established in Paris under the patronage of the Société Centrale. The statutes of the new society have been approved, and, thanks to the already large membership, it has begun operation. It proposes to establish for its contributing members retiring pensions (*des pensions de retraites*) according to the resources at its disposition, to award annual grants, and to give material aid to the contributing members, as well as to their families, when they are ill or infirm. The chief aim of the society is the establishment of a maximum retiring allowance of 360 francs. A third or two-thirds only of the retiring allowance, to mature at 55 or 60 years of age, may be subscribed for with premium accordingly, or after 15 annual payments when entrance to the society takes place after the age of 45. The premiums, which may be paid every three or every six months, may go either to the assignable or to the reserved capital. In the latter case the premiums paid are always returned to the heirs of the deceased, whether the latter had retired at the time of his death or not.

The Treatment of Obesity.

M. Pron reported recently to the Société de Thérapeutique two cases of obesity which were markedly improved by a regimen in which the value in calories of the food allowed was completely ignored, regard being paid only to its digestibility; there was also in these cases a notable diminution of physical exercise. These observations show that, even when there is, or seems to be, disturbance of the internal secretions (*dysendocrinie*) to which obesity is thought to be attributable, the antidyspeptic regimen and the diminution of exercise diminish adiposity to an appreciable extent. The cessation or diminution of the irritation exercised on the solar plexus and the cerebro-spinal nerve system modifies the respective trophic centres and allows them to impress on the phenomena of nutrition, as on those of the internal glandular secretion, a normal or nearly normal functioning.

The Royal Institute of Public Health.

The Royal Institute of Public Health of London will hold its annual congress at Paris from May 15th to 19th. A French committee, of which Professor Landouzy is president and Dr. Marié-Davy secretary-general, is taking part in the organisation of the congress.

April 21st.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Medical Attendance for English Women in India

A LAHORE paper goes into this question at some length. It points out that it will probably not have escaped the notice of many who are vitally affected in this connexion that out of 12 men appointed to the Indian Medical Service in the present year three are natives of India. In itself it would appear reasonable that in the Indian Medical Service, which is primarily maintained for the benefit of the Indian army, there should be a fair proportion of those inhabitants of the country who are able enough to qualify for the position of medical advisers to the Indian regiments. Unfortunately, however, the matter does not rest there. There is the very important question of the medical attention required by English women in this country. Rightly or wrongly, all women have a very marked preference to be attended to by medical men of their own race. To this standpoint it is quite impossible for an Indian to demur. If this is the attitude adopted as regards ordinary ailments, it can well be understood that in all matters relating to the sex such an attitude becomes immensely accentuated, and it is in the very nature of the female sex that medical advice and personal medical attention are constantly needed. Within the Indian regiments to which Indian Medical Service officers are first posted the matter is not of very great importance, because in all but the smallest cantonments other doctors are obtainable in time of need. It is, however, from the ranks of the Indian Medical Service in the army that recruits are obtained for the civil surgeoncies of the various districts, and it is in these districts that the pinch is most felt. No doubt these appointments are made by selection, and the matter of suitability for all kinds of work can be taken into consideration at the time of selection, but in the end a proportion of posts in civil employment must be given to any section of the Indian Medical Service which is sufficiently numerous. It is therefore obvious that the number of Indians in the civil surgeoncies must increase in the future. While this movement is going on, the same pressure that is exerted by other subordinate establishments is seen to be working from the ranks of the assistant surgeons. In every department alike there is the cry that promotion should not come to a dead stop within the lower grades, but that the ablest men should have a right to aspire to certain of the superior posts. There is, therefore, a tendency to increase the civil surgeoncies held by the establishment recruited in this country. Proposals have been set on foot to go even further and to encourage local practitioners to oust the official staff, whether British or Indian. These suggestions will, it is to be hoped in the interests of the country, not mature, and while Mr. Lloyd George is forming an official service of panel doctors at home it is hardly the time for the Home Government to interfere with the official system of this country. However, it is necessary to note that there is a steady decrease in the numbers of European medical men in charge of the districts in India, and it is necessary that this movement should be carefully watched in the interest of European women in the country and all that their presence means. The absence of medical advice of the type to which European women are accustomed is bound to have an adverse effect on those whose lives are to be spent in out of the way stations. The problem is a difficult one because there is a definite conflict of two interests. On the one hand it is right that the Indians who qualify themselves for superior posts should enjoy a reasonable proportion of such posts. On the other hand, if there is to be a British administration at all, care must be taken that the strength of the British officers in the various departments is not so low as to cause a loss of efficiency or a lowering of British standards. The same problem crops up in a different way in the Educational Department, where Western education has been accepted by so many whose claims to promotion within the department cannot be ignored that the future generations of Indian students will grow up imbibing an imitation of such education without ever coming into contact with any first hand exponent of Western thought.

The Question of Hospital Fees in India.

The Government of India in the Home Department have issued a resolution on the question whether persons attending hospitals and dispensaries maintained or assisted from public funds should be considered to be entitled to gratuitous medical advice and treatment irrespective of their circumstances. The Governor-General in Council has recently consulted local governments on this question, and the replies received have indicated a considerable divergence of practice in the different provinces, as also distinct differences of opinion regarding the policy which it is expedient to adopt. The Government of India, while recognising that varying conditions in different parts of the country render it impossible and undesirable to prescribe any one course for universal adoption, are of opinion that action should be taken to enforce the principle of discrimination, the acceptance of which to their mind has now become timely. The provinces averse from the introduction of a general requirement of payment are Madras, Bengal, Eastern Bengal and Assam (these inquiries were made before the redistribution of provinces) and Burma. Even in these provinces, however, medical assistance is not given entirely free. In Madras and Assam medicines, as distinct from advice, are generally paid for by persons possessing more than a minimum income. In Burma and Eastern Bengal persons of reasonable means are supposed in theory to make some return for attendance in the shape of voluntary subscriptions. On the other hand, the Government of Bombay, the Punjab, and the Central Provinces are in favour of a system of payment by persons of means. In Bombay rules directed to this end are in preparation, and in the Central Provinces experiments are being tried with a view to arriving at a satisfactory solution. In the Punjab the Lieutenant-Governor has made a public announcement in favour of the imposition of small fees, but some opposition from municipal committees is reported. The United Provinces Government, while conscious of the obstacles which have hitherto been regarded as rendering inexpedient the levy of any charge, considers that these are weakening and that the time has come to review the position. After stating the arguments commonly urged against and in favour of, the levy of a charge for attendance the Government of India announce their conclusion. They are convinced that resort is at present had to the public hospitals by persons who are in a position to pay for such benefits, and they consider that it is only fair to the growing medical profession that an effort should be made to prevent this practice. With the exception of the more backward areas it should be possible to avoid the pauperisation of the people in this matter without preventing the treatment *at the public expense of the poor* who are willing to avail themselves of the opportunity. The fear that the refusal of gratuitous relief to those who cannot be described as indigent will prejudice the progress of western science is apt to be exaggerated. Persons in comfortable circumstances have to be educated up to the recognition of a fact that they have no claim to free medical relief at the cost of the State. The Government of India, therefore, declare in favour of the introduction of an efficient system of discrimination, without prescribing any hard and fast rules for adoption everywhere. The local knowledge of those controlling medical institutions must be trusted to devise whatever method may best suit the particular conditions to be dealt with. The Government of India suggest that a beginning should be made in important urban centres, where supervision is strongest and the supply of private practitioners adequate, especially with reference to private wards in the larger hospitals. Patients who can afford to pay for separate accommodation should be charged a reasonable sum in addition for attendance and medicine, care being taken not to undersell private nursing homes or to compete with private medical men. In rural areas progress may be less rapid and must be adapted to local conditions.

March 26th.

Obituary.

RAYMOND BROADLEY ETHERINGTON SMITH, M.A., M.B., B.C. CAMB., F.R.C.S. ENG.,

ASSISTANT SURGEON TO ST. BARTHOLOMEW'S HOSPITAL AND WARDEN OF THE COLLEGE; LATE ASSISTANT SURGEON TO THE WEST LONDON HOSPITAL.

WE have to record with great regret the untimely death at the age of 36 of Mr. R. B. Etherington Smith, a rising surgeon on the staff of St. Bartholomew's Hospital, and world famous as an oarsman. The news of his death after a very short illness has come as a painful shock to an immense circle of friends and admirers. His ability, his thoroughness, and the singular charm of his character long ago marked him down for a distinguished professional career, and it is difficult to write of his loss without emotion. On Thursday, April 17th, he was found to be seriously ill. That afternoon he was operated on for general peritonitis at St. Bartholomew's Hospital by a colleague. When the organism was identified as pneumococcus the gravest fears were entertained, but everything possible was done. On Saturday morning he died in Paget Ward to the great grief of all who knew him.

Raymond Broadley Etherington Smith was born in 1877, the son of Mr. J. H. Etherington Smith, a Bencher of the Inner Temple and Recorder of Derby. From Repton he proceeded in 1895 to Trinity College, Cambridge, where he immediately made his name as an oarsman of great promise. The long story of his successes on the river has been told elsewhere. He soon reached the very front rank among amateur watermen and remained there for over ten years, taking an important part in many notable victories. He rowed thrice for Cambridge, and was President of the C.U.B.C. in 1899, when Oxford lost for the first time after nine consecutive successes. He captained Leander during four seasons, and three times rowed in the Leander boat which won the Grand Challenge Cup at Henley. His last and greatest feat on the river was in 1908, when he captained the United Kingdom eight which beat the Belgian crew in the Olympic Regatta. In rowing matters his advice and help were eagerly sought and generously given, and as a coach he brought out the best of every man.

Etherington Smith joined St. Bartholomew's Hospital in 1900. He took the M.A., M.B., and B.C. degrees in 1903, and became in turn ophthalmic house surgeon, house surgeon, extern midwifery assistant, and senior resident anæsthetist at St. Bartholomew's Hospital. In 1907 he obtained the Fellowship of the Royal College of Surgeons of England and was immediately appointed demonstrator of anatomy in the medical school of his hospital. A year or two later he became surgical registrar and demonstrator of surgical morbid anatomy, and was appointed Warden of the College, coming into residence at the Warden's house within the hospital precincts. By this time he was assistant surgeon at the West London Hospital, where he had previously been surgical registrar.

Only a few months ago Etherington-Smith was elected to the vacant post of assistant surgeon to St. Bartholomew's Hospital, and no more popular appointment was ever made. He had already begun to make substantial headway in private practice, and a distinguished future clearly lay before him. As in the past no competitor ever grudged him a victory, so it is certain that everyone would have rejoiced as he went on from success to success. His personality mastered all who came in contact with him. He had every advantage that Nature could give a man—good looks, splendid physique, brains, courage, and self-possession. To these he added perfect modesty and straightness and an engaging good humour. It is tragic beyond words that "Ethel"—as he was affectionately known to all his friends—should have been cut off before his prime. From the day he joined St. Bartholomew's Hospital, he stood out from among his contemporaries as a man of mark. Whether they wished it or not, all were drawn towards him. It was not so much the force of his intellect as the force of his personality. He charmed without conscious effort, and he impressed without the faintest trace of self-importance or conceit. On the river, in the dissecting rooms, or in the wards, he was always the same—strong, cheerful, and encouraging, with a touch of gaiety which disarmed the cynic without at all weakening influence over him.

In his surgical work Etherington-Smith was essentially sound. His temperament was not towards research, but towards activity in many other fields. Everyone felt that a great future was before him, and that he would as certainly become such an ornament to the profession of medicine as he had already become to the world of rowing. His popularity with colleagues, pupils, patients, and friends was simply the reflection of his own attitude towards the world; and the world is greatly the poorer by his death.

An intimate friend and colleague writes:—"Here, indeed, was a man. To know him was to love him. Personal beauty, physical strength, intellectual ability, and moral courage, all were his, gracefully and attractively blended. He was never self-conscious, yet always confident; a magnet ignorant of his magnetism, an Apollo who knew not vanity. Modest and generous, he touched nothing which he did not adorn—

'As the gods loved him, he died young.'

He is gone on. For us a blank remains; for him there are no regrets. In the treasury of our memories he lives, a priceless heirloom."

The funeral took place at Putney Vale Cemetery on the afternoon of April 23rd, after a memorial service at the Church of St. Bartholomew the Great, Smithfield, which was attended by a very large number of friends.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Josephus R. Lemen, formerly professor of respiratory diseases in the University of St. Louis.—Dr. Prince A. Morrow, formerly professor of genito-urinary diseases in the Bellevue Hospital Medical College, New York.—Dr. P. H. Hiss, professor of bacteriology in the Columbian University College of Physicians and Surgeons, New York.—Dr. T. Perrin, *privat-docent* of urology in the University of Lausanne.—Dr. Algernon T. Bristow, clinical professor of surgery in Long Island College Hospital, Brooklyn.—Dr. James L. Thompson, formerly professor of ophthalmology and otology in Indiana University School of Medicine, Indianapolis.—Dr. Rowland G. Curtin, formerly lecturer on Physical Methods of Diagnosis in the University of Pennsylvania, Philadelphia.—Dr. J. G. Egger, medical councillor of Landshut, who was well known for his geological and palæontological researches, at the age of 89.—Dr. Olto, who together with Dr. Neumann, professor of hygiene in Giessen, made many important investigations on the nature of tropical diseases.—Dr. T. E. Moret, *extraordinary* professor of ophthalmology in the University of Buenos Aires.

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE.—*Algeria:* Dr. Argaud has been promoted to the chair of Histology.—*Baltimore (University of Maryland):* Dr. J. A. Nydegger has been appointed Lecturer on Diseases of Tropical Countries.—*Basle:* Dr. Redinger, professor of pathological anatomy, who was offered the chair of that subject in the University of Königsberg, has decided to remain in Basle.—*Berlin:* Dr. Georg Levinsohn, *privat-docent* of Ophthalmology, has been granted the title of Professor.—*Göttingen:* Dr. Fritz Eichelberg, *privat-docent* of Psychiatry, has been granted the title of Professor.

SAMARITAN HOSPITAL, BELFAST.—As the result of a recent amateur musical and theatrical entertainment given in the Belfast Hippodrome, a total sum of £212 6*s*. 9*d*. has been handed to the treasurer of the Samaritan Hospital, Belfast, towards the reduction of a debt of £335.

CENTENARIAN.—The late Mrs. Margaret King, who recently died at Southport aged 101 years, was a native of Bristol, and was born there on June 21st, 1811. She was a niece of the Bristol poet, Robert Lovell, who married one of the three sisters, the Misses Fricker of Bath, Southey and Coleridge respectively marrying the other two.

COUNTY OF CORNWALL MEMORIAL TO THE LATE KING EDWARD VII.—The sum of £2588 has been subscribed in Cornwall as a memorial to the late King. Of this, £2500 have been invested to form a fund in aid of hospitals, nursing associations, and sanatoriums in the county. A memorial tablet to King Edward, presented by the committee, was formally unveiled in Truro Cathedral on April 19th.

ROYAL ALEXANDRA HOSPITAL FOR SICK CHILDREN, BRIGHTON.—The governors of this hospital have decided to name in perpetuity the X ray department "The Louise Sassoon Electrical and X Ray Department," after Miss Louise Sassoon, in consequence of her generosity to that department. The governors feel that the additions to the appliances will be most beneficial to the patients.

THE AFTER-CARE ASSOCIATION.—The annual report of this association shows that during the year ending December, 1912, 391 cases of poor persons discharged as recovered from asylums were dealt with. The total income was £1998. The work done by this society is worthy of the strongest support, as personal care and individual attention are bestowed on each case, and it is the only charity of its kind in the United Kingdom. The offices are at Church House, Dean's-yard, Westminster, S.W.

BRITISH SCIENCE GUILD.—A report has been drawn up by the medical committee of the British Science Guild and adopted by the executive of that association dealing with the Milk and Dairies Bill. The British Science Guild, while regarding the Bill with general approval, find that its largely permissive character will allow local authorities to ignore the powers conferred upon them. They consider that the medical officer of health is placed in an extremely difficult position in having to criticise and possibly to be instrumental in fining persons who can take his appointment away from him. Lord Haldane is the President of the association and the honorary secretaries are Sir Alexander Pedler and Dr. F. Mollwo Perkin (199, Piccadilly, London, W.).

THE METROPOLITAN ASYLUMS BOARD: THE APPOINTMENT OF A BACTERIOLOGIST.—The hospitals committee of the Metropolitan Asylums Board have reported that, in regard to a proposed appointment of a research bacteriologist, it had considered the conditions which the Local Government Board attached to its approval—namely that the officer should be designated "pathologist," that the appointment should be annual in the first instance, and that at first the officer should not be required to devote his whole time to the Board's service. The committee agreed with the Board as to making the appointment annual in the first instance; it thought, however, that the title of the office should be "research pathologist," and it was strongly of opinion that a whole-time officer should be appointed The committee quoted in support the opinion of the Board's consultative bacteriological adviser, Professor G Sims Woodhead, who wrote that the pathologist must be able to devote the whole of his time, thought, and energy to the solution of problems which had hitherto baffled many men giving their whole attention, though, perhaps, under less favourable conditions than those under which the proposed officer would work It was decided to place these views before the Local Government Board

UNIVERSITY OF MANCHESTER—The committee of the Ashby Memorial Scholarship has decided, instead of selecting a subject for research this year, that candidates shall on application for the scholarship propose their own subjects The scholarship was founded for the promotion of the study of diseases of children, and the research proposed must be in this subject The award of the scholarship will be made early in July Applications may be sent to the registrar on or before June 30th The announcement of an award previously made was due to an oversight as regards the regulations as to dates Owing to the early date of Whitsuntide the examinations for entrance scholarships and exhibitions will begin on May 19th next and be continued on succeeding days

THE *Liverpool Daily Post and Mercury* has succeeded in collecting £2000 in ten days for the purpose of supplying radium for the treatment of cancer at the Liverpool Royal Infirmary

THE SEVENTEENTH INTERNATIONAL CONGRESS OF MEDICINE, 1913

SECTION OF SURGERY

THE Surgical Section is under the presidency of Sir W Watson Cheyne, Bart, F R S, and is connected with the subsections of Orthopædics, presided over by Mr Robert Jones, of Liverpool, and Anæsthetics, with Dr Dudley Buxton in the chair The meetings of the principal section will be largely attended, and will take place in the large Lecture Theatre on the ground floor of the Imperial College of Science and Technology

The list of set subjects for discussion are · 1 The Operative Treatment of Malignant Disease of the Large Intestine, excluding the Rectum, introduced by Professor Bastianelli, of Rome and by Professor Korte of Berlin 2 A discussion conjointly with the Section of Neuropathology on the Treatment of Tumours of the Brain and the Indications for Operation Professor Bruns of Hannover, Professor Harvey Cushing, of Harvard University, Professor von Eiselsberg, of Vienna, and Dr Howard Tooth will speak 3 A discussion on the Diagnosis and Treatment of Early Renal and Vesical Tuberculosis will be held jointly with the Section of Urology It will be introduced by Professor Legueu, of Paris, by Professor Rochet of Lyons, and by Dr Wildbolz, of Berne 4 The Surgery of the Arterial System will be reported upon by Professor Matas, of New Orleans, and by Professor Oppel, of St Petersburg 5 Intrathoracic Surgery will be considered on the last day of the Congress by Professor Sauerbruch, of Zurich, and Professor Tuffier

Papers will also be read by individual members Many have already been received, but it is noteworthy that they all come from abroad, and no English surgeons have yet offered any contribution There seems too, to be some ill-defined idea that the section is a gathering of London surgeons who are inviting their colleagues from other countries This is in no sense true It is the surgeons of the United Kingdom who are endeavouring to make an international congress as truly representative of British surgery as is possible The vice presidents, the council, and the secretaries of the section have been chosen, therefore with a due regard to representation of surgery in England Scotland, Ireland, and His Majesty's overseas dominions

The sectional work of the social side of the Congress is also in an advanced state of preparation, thanks largely to the energy of an influential ladies' committee under the direction of Lady Watson Cheyne It is proposed amongst other things, that a party of 100 surgeons and their wives shall be shown round the University of Cambridge on Saturday, August 9th, where they will be received by Mr Howard Marsh, the Master of Downing College, who is also professor of surgery in the University By the kind permission of the Master and Warden of the Company there will be a personally conducted party of 70 surgeons and their wives or daughters to Barbers' Hall, which is situated in the heart of the City of London and is rarely accessible to visitors The hall is interesting from its historical associations as well as its architecture and art treasures It has remained on the same spot for at least 900 years, and thus represents the cradle of English surgery No sectional dinner will be held, but this omission will be more than supplied by the offers of private hospitality which have already been received The Hon W F D and the Lady Esther Smith have invited members of the section to a garden party at Henley, and the ladies' committee will hold an afternoon reception in the Botanical Gardens

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

Housing of the Working Classes Bill

IN the House of Commons on Friday, April 18th the second reading of the Housing of the Working Classes Bill was carried It follows the lines of the measure brought in last year by SIR A GRIFFITH BOSCAWEN A special department of the Local Government Board is proposed to be created for the purpose of seeing that the Housing Acts are enforced Grants to the amount of £1 000 000 are also suggested in order to aid in erecting suitable dwellings Mr BURNS the President of the Local Government Board declined to devote public money in this direction but was willing that the Bill should be allowed to proceed to a committee in order that its administrative provisions might be examined

The Medical Officers of Health Superannuation Bill

The council of the Royal Sanitary Institute is petitioning Parliament in favour of this Bill which has been introduced by SIR PHILIP MAGNUS, believing that it would tend to the better administration of the Public Health Service if superannuation were provided for public health officers

The Select Committee on Patent Medicines

The Select Committee on Patent Medicines of the House of Commons had a further meeting on Thursday, April 17th Evidence from the standpoint of the owners of proprietary medicines was submitted

HOUSE OF COMMONS

WEDNESDAY, APRIL 16TH

Medical Contracts in Scotland

Major HOPE asked the Secretary to the Treasury whether he would [illegible]

Motor Ambulances

SIR JOHN RANDLES asked the Chancellor of the Exchequer whether [illegible]

The Health of Naval Cadets

Major GASTRELL asked the Civil Lord of the Admiralty whether anything had been done to eradicate the danger of disease at the Royal Naval College Osborne and whether, if nothing could be done to [illegible]

Lord **CHARLES BERESFORD**: Is it not a fact that these epidemics are very constant at Osborne and more constant than in ordinary schools of public instruction in the country, and can he see his way to do something to alter that position?—Mr. **LAMBERT**: This question is under the constant care of the Admiralty. I understand that boys when they enter Osborne at 12½ years of age are peculiarly susceptible to these diseases.

Lord **CHARLES BERESFORD**: Will the honourable gentleman answer my question? Are not epidemics at Osborne more constant than they are in the ordinary public schools of the country?—Mr. **LAMBERT**: Not if you take the age at which the boys enter into consideration. I shall be very happy to consider any information which the noble lord can give me.

Preservatives in Cream.

Mr. **CHARLES BATHURST** asked the President of the Local Government Board whether his attention had been drawn to the action of the Westminster City Council in threatening proceedings under Section 3 of the Sale of Food and Drugs Act, 1875, against retail dealers and stores, in respect of the sale of preserved cream containing less than 22 grains of boracic acid to the pint, on the ground of injury to health; and, whether, seeing that Dr Hamill, the medical inspector of the Board, recommended in a recent report to the Board, after elaborate inquiry, that a quantity up to 28 grains might be permitted in the summer months without injury to health, the Board would issue a circular advising local authorities that no proceedings ought to be taken provided sales were made in compliance with the recently published regulations and where the quantity of preservative did not exceed Dr. Hamill's recommendation.—Mr. **BURNS** said in reply: The answer to the first question is in the affirmative. I do not consider it is necessary, at any rate at the present stage, to issue such a circular as the honourable Member indicates.

Rural Housing.

Lord **HENRY CAVENDISH-BENTINCK** asked the President of the Local Government Board whether his attention had been directed to the report of Dr. Webb to the Kingsbridge (Devon) rural district council, where he stated that one-eighth of the cottages in the district were unfit for human habitation, but that there was nowhere for the people to go if these we[illegible] discussion took place, but no action was taken [illegible] what action he intended to take in the matter.—[illegible] I have not yet received the report of the medical officer of health for the Kingsbridge rural district for the year 1912, and the latest report in my possession did not indicate the existence of any such unsatisfactory conditions as to render necessary action on my part. I will look into the matter.

Lord **HENRY CAVENDISH-BENTINCK** asked the right honourable gentleman whether his attention had been called to the report of the medical officer of health for the Sedgefield rural district council in respect to houses at Trimdon Grange and Trimdon Colliery, where he stated that after inspection of 63 houses he found all but six unfit for human habitation on account of bad sanitation and ventilation, and recommended to the council that closing orders should be issued and that the council should erect new dwellings for the people displaced, and that the rural district council resolved to apply for closing orders but referred the question of the erection of new cottages to the Trimdon sanitary committee; and whether he would state what steps had been taken to accommodate the tenants thus displaced.—Mr. **BURNS** replied: The council decided in January last to build 25 houses, and applied to the Local Government Board for sanction to a loan for the purpose, but they have not yet furnished the particulars necessary before the application can be further dealt with. I am sending a further letter to them on the subject.

Lord **HENRY CAVENDISH-BENTINCK** asked the right honourable gentleman whether his attention had been called to a special report of the housing committee appointed by the Ramsbury (Wilts) rural district council, which stated that out of 52 cottages in the village of Axford ten had one bedroom only, whilst only seven had three bedrooms; that five cottages were overcrowded, three unfit for habitation, seven were dilapidated, and 26 needed general repairs; and that, while the Ramsbury rural district council admitted the need for more cottages, they had decided to defer action in regard to building; and whether he intended to take any steps in the matter.—Mr. **BURNS** said in reply: I have been in communication with the Ramsbury rural district council in regard to the need for the erection of cottages at Axford for some time, and on the 31st ultimo the chairman had an interview at the Local Government Board in regard to it. The matter will not be lost sight of.

Lord **HENRY CAVENDISH-BENTINCK** asked the right honourable gentleman whether his attention had been directed to the report of the medical officer of health for Cornwall, in which he stated that the problem of consumption was largely the problem of housing, yet bad housing was suffered to continue; that housing in Cornwall constituted one of the greatest barriers to sanitary progress; that many cottages had no backyards and no sanitary conveniences; that many local authorities had not yet adopted housing schemes where it had clearly been their duty to do so; that Dr. Burnet further reported a dearth of houses in eight of the 16 rural districts of the county—namely, Boscastle, Camelford, Liskeard, St. Colomb, St. Austell, Truro, East Kerrier, and West Penwith—whilst it was stated in regard to the Bodmin rural district area that many houses should be condemned absolutely, as they rendered their occupants much disposed to phthisis; and whether he would state what action, if any, had been taken with regard to these areas.—Mr. **BURNS** replied: I have seen the report for 1911, and note that the county medical officer of health is fully alive to the powers of the county council under Sections 10, &c., of the Housing, Town Planning, &c., Act, 1909 I am keeping an eye on these districts in connexion with the reports of the local medical officers of health for 1912, which I am now receiving, and I am with the county medical officer of health in hoping that it may not be necessary for the county council to use their powers under the sections.

Mr. **C. DUNCAN**: Can the right honourable gentleman bring pressure to bear upon these local authorities?—Mr. **BURNS**: We are consistently doing that.

Supply of Government Calf Lymph.

Mr. **COURTHOPE** asked the President of the Local Government Board whether, in view of th[illegible]ood quality as the Governm[illegible]ons of independent means [illegible] he would allow medical practitioners to purchase Government vaccine for use upon their private patients.—Mr. **BURNS** wrote in reply: This matter has been considered by the Local Government Board on more than one occasion, but they have not hitherto found it practicable to take action in the direction suggestion.

THURSDAY, APRIL 17TH.

Sleeping Sickness South of the Zambesi.

Answering Mr. **GINNELL**, Mr. **L. HARCOURT** said that there was no reason to suppose that sleeping sickness was generally prevalent south of the Zambesi.

MONDAY, APRIL 21ST.

Medical Panels in Ireland.

Sir **JOHN LONSDALE** asked the Secretary to the Treasury to state in which counties and county boroughs in Ireland panels of doctors had been formed in connexion with the National Insurance Act; and to explain why circulars were issued by the Irish Insurance Commissioners stating that panels had been formed in every county and county borough in Ireland when panels had not been formed in many cases.—Mr. **MASTERMAN** replied: I am informed by the Irish Insurance Commissioners that no such circulars as are referred to in the question have been issued by the Commissioners. I understand the honourable baronet to refer to a paragraph in a specimen copy of a form that is intended to be used when the panel system is working, which was issued to doctors for the purpose of explaining their duties under the panel system. That it was not intended as a statement that panels had already been formed is shown not only by the character of the form, but by the fact that it was issued to the doctors, who alone received it before the date by which they were asked to have sent in their names for the panels. I am informed by the Commissioners that sufficient doctors have already intimated their willingness to serve to enable panels to be formed in the following areas:—County boroughs: Belfast, Cork, Londonderry. Counties: Antrim, Armagh, Clare, Cork, Donegal, Down, Fermanagh, Londonderry, Longford, Mayo, Monaghan, and Sligo.

Certification Rates under National Insurance Act in Ireland.

Sir **JOHN LONSDALE** asked the Secretary to the Treasury whether he was aware that the conjoint committee of the Irish Medical Association and British Medical Association received a definite pledge that a minimum capitation rate of 2s. 6d. would be provided for certification in the event of medical benefits for Ireland being deleted from the National Insurance Act; and if whether, in redemption of this pledge, he intended to make a further grant to enable the Irish Commissioners to meet the financial difficulties in the way of the efficient working of the Act in Ireland.—Mr. **MASTERMAN** replied: The answer to the first part of the question is in the negative. The second does not therefore arise.

TUESDAY, APRIL 22ND.

Free Choice of Medical Men.

Sir **J. D. REES** asked the Secretary to the Treasury whether the Bill to amend the Insurance Act would provide for free contracting out, for real choice of medical attendant, and for exclusion of married women outworkers.—Mr. **MASTERMAN** said in reply: The answer is in the negative. The first and third proposals of the honourable gentleman are open to the gravest objections, and the second is already provided for in the existing Act.

Viscount **VALENTIA** asked the right honourable gentleman whether he was aware that much indignation was felt by a considerable number of railway employees resident in the city of Oxford who were unable to avail themselves, under the provisions of the National Health Insurance Act and [illegible] relating thereto, of the services of a doctor who [illegible]o, though willing to go upon the p[illegible] having obtained the consent of th[illegible] precluded by the intervention of the panel doctors, in spite of his frequent assurances that every insured person had a right to choose his own doctor; and would he take steps to provide for the services of the doctor hitherto employed by these men being made available for them.—Mr. **MASTERMAN** answered: I have made inquiries of the Oxford Insurance Committee on this case. Acceptance of a limited number of insured persons by a doctor on the panel is only possible where attendance by doctors on the panel is assured for all insured persons in the area, and therefore can only be granted by an Insurance Committee with the consent of the doctors on the panel. The responsibility for treatment of the insured persons must be a collective one, and no one doctor can be allowed to select good lives amongst insured persons with the same remuneration per head as those who would accept a general average.

Insured Persons and Change of Medical Men.

Mr. **JOHN TAYLOR** asked the Secretary to the Treasury whether he was aware that a certain number of insured persons connected with the lodges of the Durham Miners' Association were desirous of changing their doctor; that, when they signed for their present doctors, it was on the understanding that it held good for three months only; and that objection was now taken by the Insurance Commissioners to the transfer on the ground that the present arrangements held good for 12 months; and whether he would inquire into the matter with a view to the initial understanding being adhered to and the men being allowed to make the change of doctor desired.—Mr. **MASTERMAN** said in reply: My attention has been drawn to the matter to which my honourable friend refers, and I am investigating the circumstances referred to. In general, insured persons may change their doctors within the year either by consent of doctor and patient or by consent of the Insurance Committee on complaint of the medical treatment received.

WEDNESDAY, APRIL 23RD.

Contributions to Medical Aid Associations.

Captain **KNIGHT** as[illegible] the Treasury whether there was any obligation on [illegible] to make payments, in advance or otherwise, [illegible], approved under the Act, on account of members of Approved Societies who desired to take their medical benefit through such associations; and, if so, whether such payments ought to be made on the same dates as those made to panel doctors.—Mr. **MASTERMAN** wrote in reply: An Insurance Committee may contribute towards the expenses of the treatment furnished by an approved institution to insured persons who are members of the institution [illegible]

institution on any date that may be convenient.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention should be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed " To the Sub Editor "

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed " To the Manager "*

We cannot undertake to return MSS not used

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W C, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c, should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows —

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs 50 per month)

Subscriptions (which may commence at any time) are payable in advance Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W C

TO COLONIAL AND FOREIGN SUBSCRIBERS

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied

A Lecture

ON

BIRTH PALSY: SUBLUXATION OF THE SHOULDER-JOINT IN INFANTS AND YOUNG CHILDREN.

Delivered at the Hospital for Sick Children, Great Ormond-street, on March 4th, 1913, as one of an Advanced Course of Lectures arranged by the University of London,

BY H. A T FAIRBANK, M S LOND, F R C S ENG,

SENIOR SURGEON TO OUT PATIENTS TO THE HOSPITAL, ORTHOPÆDIC SURGEON TO CHARING CROSS HOSPITAL, ETC

GENTLEMEN,—I have chosen the subject of birth palsy for my lecture this afternoon because the treatment of this condition does not appear to me to be adequately dealt with in text-books, and also because one result of this paralysis—namely, subluxation of the shoulder joint—has received little or no attention in this country My remarks will be based largely on a personal experience of cases seen during the last few years, of 40 of which I have notes I should like to say now how greatly I am indebted to my colleagues at this hospital, without their generous coöperation it would have been impossible for me to examine and treat so many as 35 cases in the last three years or so

BIRTH PALSY

Birth palsy—i e, palsy produced during and dating from birth—is due, as you know, to injury to the brachial plexus [illegible] It is now generally accepted [illegible] out by traction on the nerves, [illegible] or completely torn This traction is produced during labour by forcible deviation of the head and neck away from one shoulder which is temporarily fixed It is easy to see how such a condition can occur during a forceps delivery when one shoulder is hitched above the brim of the pelvis or in a breech presentation when the after coming head is born with difficulty The view that compression by the clavicle produced the damage has been disproved by experiments on the cadaver (Clarke, Taylor, and Prout[1]) and by observations on the situation of the lesion, which is usually well above the level of the clavicle, during the course of operations upon the plexus It is stated that the paralysis occurs equally (Tubby[2]) or nearly equally (Sherren[3]) in head and breech presentations My series of cases does not bear this out, since in 32 the vertex had presented, only 7 were breech cases, while one was turned and delivered by forceps In support of these figures, small though they are from which to draw conclusions, I might point out that though the first five cases do not represent nearly all the cases seen at that time, the last 35 include practically all the patients examined during the last three years or so and diagnosed as birth palsy, and therefore can be regarded as a consecutive series As a rule, this lesion only follows difficult labour, whether the vertex or breech presents, but in rare cases labour has been easy and normal In most of the vertex cases forceps were used Further details of the history of parturition obtained in this series will be given in the latter part of the lecture

Nature of Lesions

The actual damage to the nerve varies from slight tearing of the perineural sheath and hæmorrhage into the nerve itself, to complete tearing through of the nerve trunk The milder types of damage are by far the more common, for it is a well-established fact, only disputed by one or two (Bruns[4]), that in the majority complete recovery ensues The exact distance from the cord that the nerve yields seems to vary The anterior primary division of one or more nerves may be actually pulled out, more or less completely, from the spinal cord, which naturally also suffers Much more commonly the nerves or trunks of the plexus are torn, while Kennedy[5] found the commonest seat of all to be at the point of junction of the fifth and sixth cervical roots to form the upper trunk of the plexus I would refer you to a paper read by G F Boyer[6] in the Neurological Section of the Royal Society of Medicine last year, in which he gives a detailed account of the condition of the plexus, cord, and brain in a case of obstetric paralysis, a female who died at the age of 41 The traction to which the plexus had been subjected at birth had nearly succeeded in pulling all the component nerves out by their roots, the origin of the seventh cervical nerve from the cord being the point of greatest damage Boyer found the opposite side of the cord distorted and otherwise altered by the injury and resulting fibrotic changes He expresses the view that in severe and persistent cases of paralysis resulting from obstetric trauma the probability is that the cord is injured much more frequently than is generally considered Burr[7] in 1892 expressed a similar view However true this view may be, there is no doubt that the lesion usually consists of a partial tearing of one or more nerve trunks some distance from the spinal cord, and that the damage stops short of complete division

It follows from the mode of production of the damage in these cases that the upper part of the plexus—i e, the most obliquely running nerves—will suffer most, and this is undoubtedly the case *In the vast majority the paralysis* is of the upper arm or Erb Duchenne type, sometimes the whole plexus is affected, while very rarely only the lowest trunks are damaged, giving rise to the lower arm (Klumpke) type of paralysis with involvement of the cervical sympathetic The latt[illegible] shoulder in the [illegible] nerves that suffer [illegible] cases the seventh cervical is damaged in addition, while, as already stated, occasionally the whole plexus is damaged. It is a disputed point as to whether 6 C is necessarily damaged or not in a case showing the typical paralysis Harris and Low[8] maintain that division of 5 C alone can produce the characteristic paralysis It must always be remembered in connexion with the brachial plexus that it is subject to considerable variation It may be pre fixed or post fixed, and the exact distribution of a particular spinal nerve can only be determined with accuracy by direct stimulation of the nerve in the course of a surgical operation I am inclined to regard 6 C as a sort of odd job nerve since clinically it is often, if not usually, impossible *to distinguish between a lesion of 5 C alone* and one of 5 and 6 C together 5 C often provides the sole, or practically the sole nerve supply to certain muscles, whereas this is not the case with 6 C

As to the lesions I have myself observed in the course of operations on the brachial plexus in five cases in one (Case 5) which presented the typical paralysis, the 5 C alone was scarred and surrounded by fibrous tissue just at the outer border of the scalenus anticus The phrenic nerve was involved in the scar tissue 6 C was normal in appearance, and direct stimulation produced vigorous contraction of the pectoral and of some muscles in the forearm, but it was not considered advisable to disarrange the sterilised towels sufficiently to make further investigations Stimulation of 5 C produced contraction, definite but not vigorous, of the deltoid, particularly the anterior part the biceps and the supinator longus, and the infraspinatus almost certainly Contraction of the supraspinatus was uncertain The fifth cervical and phrenic nerves were freed from all scar tissue, and the sheath of the former was incised longitudinally In doing this one definite constricting band was divided Cargile membrane was wrapped round the nerve before the wound was closed The child was 10 months of age when operated upon and presented the typical vertically hanging arm, with the usual muscles still almost completely paralysed These muscles responded so feebly to the faradic current that in several the response was uncertain Paralysis of one side of the diaphragm was not looked for before operation, but soon after no sign of this could be made out

Case 2, an infant of 8 months, was seen in 1906 before I had realised the frequent occurrence of subluxation, but limitation of external rotation at the shoulder was noted No response to faradism could be obtained in the spinati and supinator longus, and only very feeble response in the deltoid, biceps, and extensors and flexors of the wrist and fingers The triceps and serratus responded briskly At the operation the whole plexus was found to be involved in one sheet of scar tissue I had the greatest difficulty in reaching

traumatism at birth, but I believe the cases in this series to be all cases of subluxation secondary to paralysis. There is one possible exception, a child with double congenital talipes with very deficient musculature of the legs, double congenital drop-wrist and claw hand, and a left posterior subluxation of the shoulder. The shoulder condition agreed in every way with what was found in the other members of this series, and labour had been extremely difficult, but the association of the other deformities, undoubtedly of congenital origin, must throw some doubt on the case.

I will now give the grounds upon which I base my belief that in all the other cases in this series (28) a birth palsy has preceded and caused the subluxation.

1. A history of difficult labour. Of 23 in which the head presented, 21 are said to have been definitely difficult, and in 15 of these forceps were used. In 1 the arm was broken, in 2 the arm was over the head, and in 1 the face presented and the arm was over the head. Of the 5 breech presentations 3 were difficult. The clavicle was broken in one, in another the arms were extended, while in a third there was a contracted pelvis. In many the child was absolutely black at birth. In almost every case, therefore, labour was difficult, and damage to the plexus more than possible.

2. A history of paralysis after birth. In 23 out of the 28 the arm is said to have hung limp and vertical at first—i.e., to have been in the position seen in birth paralysis. In one the arm was behind the back. Six cases were actually seen soon after birth by one of my colleagues or myself and diagnosed as birth palsy. Another was certainly diagnosed at birth as a dislocation by the medical attendant, yet the arm hung limp from the shoulder, so it is likely that he was mistaken.

3. The plexus lesion proved in one case. In a case in which I operated upon the plexus, some time before I discovered the subluxation, the plexus was obscured throughout by a mass of fibrous tissue. This does not, of course, entirely discount the possibility of the dislocation and the plexus lesion having resulted from the same injury.

4. The presence in the series of all degrees of displacement of the head of the humerus; and at the same time while in some of the younger ones the subluxation was completely reducible, in the older cases the displacement was fixed. It was possible in the series to trace the gradual development and fixation of the displacement. In 5 the subluxation was completely reducible, and in 5 partially reducible.

5. The presence of some residual paralysis which could not possibly result from pressure of the displaced head of the humerus.

The following details of the series may be of interest before I pass on to the treatment. The two arms were affected in an equal number of cases. There were 20 males and 8 females. Half of the cases—i.e., 14—were under 1 year of age; between 1 and 2 years there were 5 cases; under 3 years, 2 cases; exactly 3 years, 1 case; 6 years, 1; 7 years, 2; 9 years, 10 years, and 11 years, each 1. The earliest age at which I have seen a reducible subluxation is 2 months and an irreducible subluxation 4 months. In 18 no sign of paralysis could be detected, and in most cases this was verified by electrical examination under an anæsthetic. Of the 10 remaining cases 7 showed some weakness of the extensor muscles on the back of the forearm, the common extensor of the fingers being the muscle most often affected. It is noteworthy how difficult it is to stimulate this muscle by an electrode, even in a case where it is certainly healthy. In one (Case 13) no response was obtained in the supinator longus, nor in the extensors of the wrist and fingers, but the child was very fat. Passive supination was not limited. The distribution of the paralysis seemed to correspond to the musculo-spiral nerve, and as the humerus had been broken at birth a little below the centre of the shaft the nerve was exposed in the arm, but was found to be normal. In another case (No. 26) the supinator and serratus magnus were paralysed, while the response of the upper part of the pectoralis major was doubtful (? 6 O.). In one (Case 2) there was a dislocation forwards and outwards of the head of the radius, apparently congenital, on the same side as the subluxation. One developed tubercular disease of a metacarpal bone, but the history was typical of a birth paralysis, and there was no sign, skiagraphic or otherwise, of tubercle of the shoulder.

Treatment.

This consists in reduction of the subluxation and retention of the limb in some form of apparatus for a sufficient time to allow the stretched tissues, capsule and muscles, at the back of the joint to contract and recover their normal condition. This period of fixation is followed by massage and exercises, passive and active, for an indefinite period.

As already stated, in 5 complete reduction was possible; these were all treated on the splint that I have shown you, together with massage and exercises. Reduction is brought about simply by external rotation of the humerus; therefore this movement, and external rotation combined with extension with the arm at a right-angle to the trunk, must be the chief passive manipulation performed by the mother.

Of the remaining cases, in 5 an attempt was made to reduce the subluxation by manipulation under an anæsthetic, as practised and recommended by Whitman.[13] The elbow is carried backwards, the arm being at a right-angle to the chest, while a thumb is placed behind the head of the humerus to act as a fulcrum. When reduction is accomplished and the tissues in front are thoroughly stretched, external rotation is gradually obtained and then full adduction. It is not always possible to obtain complete reduction at the first sitting. In one case I manipulated the shoulder on three occasions, in two cases twice, and in two once, but without satisfaction. Not once did I obtain sufficiently free external rotation, though the head could be placed in the glenoid cavity. Although I am accustomed to using considerable force in the reduction of congenital dislocations of the hip-joint, I never dared use sufficient rotary force to overcome all the muscular contracture for fear of twisting off one or other epiphysis of the humerus. In every one of these cases an open operation was eventually performed. Whitman admits that relapse is prone to occur and has to be carefully guarded against. By the open method I am about to describe this tendency to relapse is very greatly diminished if not entirely done away with. In all, 18 cases have been treated by open operation.

Operation.

The joint is reached through the usual anterior incision for excision of the shoulder, commencing at the clavicle and passing downwards and outwards in the interval between the deltoid and pectoral. After the skin has been excluded by clamping a sheet of muslin or lint to the margin of the incision, the cephalic vein is found and, as a rule, clamped above and below, the intervening portion being removed. The interval between the deltoid and pectoral is opened up and the muscles are retracted. The inner margin of the deltoid, close to its origin, may be divided for a short distance if the exposure of the deeper parts is inadequate. The long head of the biceps is then defined in its groove, the arm being rotated out to bring the groove forward. As a rule the upper margin of the flat pectoral tendon is nicked to enable this to be more easily done. The capsule is now incised in the line of the tendon as it passes inwards just above the tuberosities and the tendon exposed. The preliminary exposure of this tendon lower in the groove is simply to facilitate this exposure higher up. A bridge of tissue is left between the tuberosities to retain the tendon in its groove. The tendon is usually slender and easily damaged. All the capsule lying in front of and below the tendon is now divided, including the tendon of the subscapularis muscle which is closely connected with it. The arm should be forcibly rotated out by an assistant. If this tendon is cut close to the lesser tuberosity there is no danger of wounding the large vessels or nerves. If it is thought to be necessary, an aneurysm needle can be passed down beneath these structures from the hole made in the capsule above, and its point pushed forwards just below the tendon of the subscapularis, and then this muscle and the capsule divided upon the needle. It will now be found that external rotation is free and can be accomplished to the full extent, while this movement is accompanied by reduction of the dislocation. The head of the humerus rotates forwards and its cartilaginous surface is seen through the hole in the front of the joint. By redislocating the head and retracting the margins of the capsule a fair view of the glenoid cavity can be obtained. Adduction will still be imperfect, so the coraco-humeral ligament, which can be shown to be definitely tight, and also the supraspinatus are divided on an aneurysm needle passed beneath them to avoid chipping the head of the humerus. Sometimes the anterior fibres of the infraspinatus are probably divided before satisfactory adduction is obtained. The only vessel likely to give any trouble is the anterior circumflex. The deltoid and pectoral are brought together with a continuous catgut suture and the wound closed with a subcuticular thread stitch. The pronators of the forearm, if shortened, should be stretched. In three of my earlier cases the coracoid process seemed to project outwards abnormally and obscure the view, so it was divided temporarily and brought together again at the end of the operation with wire or fishing gut. The glenoid, as is to be expected, is shallower than normal. In a girl of 9 years the glenoid was even convex and a fibro-cartilaginous ridge passed downwards and backwards from it; this was probably an attempt at the formation of a false socket, but its exact extent could not be ascertained.

The arm is put up in the position suggested by Whitman in plaster-of-Paris (Fig. 11). The elbow is put to the side and well back, only a thin layer of wool lying between the arm and chest, the elbow is bent at a right angle, and the forearm is supinated fully and directed well outwards—i.e., the humerus is rotated out fully. I usually put a pad of cotton wool behind the upper end of the humerus and another over the shoulder to keep down the scapula and prevent recurrence of the abduction. The arm is retained in this position for three months, the plaster being renewed when the wound is dressed on the tenth or fourteenth day, and again later if necessary. After removal of the plaster, massage, passive movements, particularly extension of the shoulder, external rotation of the humerus, and supination are persevered in for many months. If only the services of a skilled masseuse can be obtained the result should be excellent. Unfortunately, among hospital patients there are few who can make use of their opportunities for regular massage, so the results I have obtained are not so good as they ought to be. Nevertheless, the results are, in my opinion, sufficiently good to justify amply the operative treatment. In every case treated by open operation the head of the humerus is now in its normal position in relation to the scapula, and the external rotation of the humerus is maintained. (Figs. 9 and 10.) Parents have been satisfied with the advantage to the child resulting from the operation, even in cases that I know could have been much further improved by prolonged and skilled massage, &c. In those few that have received more adequate after-treatment the results are excellent.

It must be remembered that the shoulder joint is probably the very worst joint in which to obtain free mobility in a child. It is well known how readily a child will restore, unaided, perfect movement to a joint after acute arthritis. In the case of the shoulder a young child can do practically anything he wants to without moving the shoulder-joint itself, the scapula being so freely movable. As a result the infant does little or not[illegible] in fact, he hinders the [illegible] ing to the utmost. [illegible] limb after operative re[illegible] much better use of his hand and forearm, the muscles of which are usually healthy.

Finally, it seems to me obvious that massage and exercises are to a large extent wasted on an arm crippled by a subluxation of the shoulder, and that replacement of the head of the humerus in the glenoid cavity must precede all other efforts to restore the function of the limb.

In conclusion, I wish to offer my sincere thanks to the Senate of the University for the honour they have done me in inviting me to deliver this lecture.

LITERARY INTELLIGENCE. — Messrs. Baillière, Tindall, and Cox announce for immediate publication a new edition of Castellani and Chalmers's "Tropical Medicine." The new edition has been revised up to March, 1913. Some 250 new illustrations have been introduced, and the text has been increased by the addition of about 500 pages. The price, however, remains the same.

A CASE OF ANKYLOSTOMIASIS IN BIRMINGHAM.

BY ROBERT SAUNDBY, M.D. EDIN., F.R.C.P. LOND. AND IREL., LL.D. MCGILL AND ST. AND., M.SC. BIRM.,

PROFESSOR OF MEDICINE IN THE UNIVERSITY OF BIRMINGHAM; CONSULTING PHYSICIAN TO THE BIRMINGHAM GENERAL HOSPITAL.

A MINE foreman, aged 42, was sent to me by Sir Havelock Charles on Dec. 12th, 1912, complaining of attacks of fulness with splitting or boring pain in the head which had been troubling him for the last eight months. He had fallen down in these attacks and lost consciousness. For nine years he had been a foreman in a coal-mine in Assam, but returned home in September on this account. On the whole he had enjoyed very good health, with the exception of occasional bouts of malarial fever of the ordinary ague type, but he had had none of these since the hot weather of 1911. Eighteen years ago he was in a mine accident as the result of a fall of coal, but he recovered completely and had had no recent injury. He is married and steady in his habits, taking very little alcohol; he denies syphilis. A year ago he was treated for "hookworm disease."

On examination he was a well-developed, well-nourished man; complexion dark and pale, but he said he was always pale; his mucous membranes were a good colour; weight, 13 st. (he was 11 st. 6 lb. before leaving India); pulse 72; blood pressure 124; knee-jerks lively; physical signs normal; tongue clean; teeth mostly artificial, no stumps; hæmoglobin 80 per cent.; urine acid, no albumin, no sugar. The ophthalmoscopic appearances were negative, and there was no history of epilepsy. On being further questioned he said the attacks came on generally when he rose suddenly to his feet, but might do so when he was sitting quietly in his chair. As nothing else could be found to account for his symptoms it was suspected that ankylostomiasis might still be present.

On Dec 11th he was given thymol, 60 gr., divided in two doses, and on examination of the stool passed subsequently a male and a female ankylostomum (Ankylostoma duodenale Dubini) were found together with numerous ova. There were traces of blood in the stool. The treatment was repeated on the 27th, when the small smear of fæces sent to me afterwards contained numerous ova but no worms. The thymol was repeated again on Jan. 10th and 24th. As ova were still numerous he was admitted into a bed at the Bi[illegible] General Hospital, placed at my [illegible] The blood, examined by Dr. O. [illegible] officer, showed: Red cells, 4,400,000; leucocytes, 7560; hæmoglobin, 80 per cent.; colour index, 88. Differential count of leucocytes: polymorphonuclears, 72; eosinophiles, 6; lymphocytes, 20; and large mononuclears, 1.

The patient said that his head attacks had been less frequent, but as the ova were still abundant the thymol treatment was repeated on Feb. 7th. On the following day one worm was found in the stool, which also contained a little blood. Mr. James F. Brailsford, of the Public Health Laboratory, University of Birmingham, who undertook to examine the stools, subsequently found two more worms, as well as numerous ova of ankylostomum and of trichocephalus. The patient complained that the thymol treatment caused a good deal of burning pain with subsequent depression; his urine was darkened with it. The dose of thymol on the last three occasions had been increased to 90 gr. On account of these disagreeable results it was decided to try oil of chenopodium, recommended by Schueffner as having proved satisfactory in the treatment of this disease in the Dutch East Indies. The dose given was 20 m in 5 m. capsules—three capsules at 8 A.M. and three more at 10 A.M., preceded and followed by purges as with thymol. It was tried on Feb. 19th and 21st, but no adult worms were found, although numerous embryos and ova were seen. He was allowed to go home after the second dose.

The thymol treament (90 gr.) was continued at home. On March 1st the patient reported that he had had another slight giddy attack. On the 11th he took 120 gr. of thymol; ova and embryos were still present. On the 25th the above treatment was repeated, but the stools on the 27th still con- [illegible] 1st he was given eucalyptus [illegible] by Dr. C. W. Daniels—

eucalyptol 30 m., chloroform 45 m., castor oil 10 drachms, divided into two doses taken at an interval of one hour, and preceded and followed by sodium sulphate as before. He complained of the mixture as very nauseous, and had vomited slightly after the second dose. Three days later he suffered from palpitation, which lasted four days, and when seen by me on April 10th his pulse was 60, but intermitting every fifth or sixth beat. Ova and embryos were still present in the fæces. Whether the cardiac disturbance was the direct effect of the eucalyptus oil or the indirect result of the gastritis set up by the mixture I cannot tell, but in either case I did not think it advisable to repeat it, and have returned to the use of thymol.

Five years ago Professor Ralph Stockman, of Glasgow, published a case of ankylostomiasis in a miner living in the west of Scotland who had been a soldier in India and apparently had been infected in that country. He showed the signs of marked anæmia, his hæmoglobin being only 28 per cent. After three doses of 20 gr. of thymol and a course of Blaud's pills his blood became normal and ova disappeared from the fæces, or their presence was no longer looked for.

The method of administering thymol which has been followed is that recommended by Dock and Bass, the drug being finely powdered with an equal quantity of sugar of milk and given in cachets or capsules; 1 oz. of sodium sulphate is given the previous night, and the same amount two hours after the last dose of thymol. The dose of thymol has varied from 60 to 120 gr. Fasting has also been insisted upon during the day preceding treatment, although the patient has been allowed to drink hot or cold water, soda water, milk and water, bouillon or bovril; and on the second day no food was allowed until after the final dose of sodium sulphate had been taken. The patient was kept in bed until after the bowels had acted in the afternoon of the second day, but he was advised, although not compelled, to stay in bed the whole of that day. I found the patient was generally more or less upset by the thymol; he felt ill, often complained of burning pain behind the sternum, and his urine was dark, so that he was usually content to stay in bed.

Ankylostomiasis is common in Assam, where its prevalence among the coolies on the tea-gardens has made it of considerable economical importance, owing to the reduction of efficiency in the working capacity of affected persons as well as to its by no means inconsiderable mortality. A warm, damp climate like that of Assam is especially favourable to the worms, as the ova require heat and moisture for their development after their escape from the bowel. They hatch and the embryos grow rapidly in warm mud, whence they are readily transferred to the naked feet and legs of Indian coolies. It is now believed that the larvæ gain access to the body by penetrating the skin, and that this is the most usual mode of infection. Penetration of the skin is an affair of minutes only—four minutes according to one estimate (Bass). Looss accidentally infected himself by allowing a drop of a culture of the larvæ to fall on his hand; a few minutes later he felt a lively itching and scraped the surface of the skin, which under the microscope showed a number of empty moults or discarded outer coverings of the embryos; three months later ova were found in his stools.

In answer to my questions the patient assured me that he had never gone about with bare feet or with any part of his body unclothed except his face and hands, but as portions of the mine under his supervision were some miles from his bungalow he was in the habit of taking food in his pocket to eat for lunch, so that it is probable that infection in his case has been by the mouth. It is possible that the skin of his hands might have been infected, but as infection of the skin is signalised by a rash (ground itch, Bentley), which he denies having had, infection by the mouth is more probable.

The symptoms shown by this patient are unusual. Vertigo, noises in the ears, mental depression, and apathy have been commonly observed and attributed to anæmia, but the report on the blood and the state of the mucous membranes are inconsistent with this explanation of the attacks. If the symptoms depend upon the presence of the parasite, as I believe, it is more likely that they are the effect of a poison secreted by the worms comparable with that which is formed by bothriocephalus. "Giddiness, epileptiform seizures, chorea, hallucinations and other neuroses" have been attributed, apparently with justice, to the presence of tapeworms; hysteria, convulsions, and chorea to threadworms; vertigo, hysteria, convulsive seizures, and mental disturbance to round worms; but in the accounts of ankylostomiasis the references to nervous disorders are scanty. Brumpt mentions vertigo, noises in the ears, impaired vision, mental depression, and apathy; Manson, tinnitus, vertigo, dimness of sight, mental apathy, and depression; Dock and Bass, headache, dizziness, mental dulness, insomnia, loss of knee-jerks, impotence, diplopia, nystagmus, and melancholy; Austregesilo and Gotuzzo have reported a case of delusional insanity cured by expulsion of the worms; and Macdonald has met with "moral perversity." But all these symptoms are such as might be caused by anæmia or by greatly impaired general health, which is often profoundly affected, but my patient's aspect is healthy; he has gained nearly 2 st. in weight since leaving India, and his organs of digestion and assimilation appear to be performing their work perfectly.

The presence of traces of blood in the stool is in accordance with the usual experience. The evidence in my case was a positive reaction with Boas's benzidine and peroxide of hydrogen test, but the amount was small. The worms undoubtedly suck blood and their alimentary canals are often full of blood when they are expelled, but the quantity lost by the host in this way is not estimated to be serious. It is supposed that the worms shift their position, frequently leaving wounds which bleed; some suppose that a more important cause of anæmia is the presence of a hæmolytic toxin demonstrated by Whipple, and the toxic effect is greater than the loss of blood. Looss believes that the worms not only suck blood but feed on the mucosa, but Dock and Bass express some doubt of the frequency of this occurrence.

The amount of eosinophilia present in this case was slight; it is now recognised that this blood change is most significant of parasitism, but it is not constant and may be absent in quite severe cases (Dock and Bass). In Stockman's case the eosinophilia varied from 12 to 43 per cent. of the total leucocytes. Boycott and Haldane in their report on the outbreak of the disease in Cornwall do not refer to this point. According to Dock and Bass the presence of eosinophilia shows that things are not so bad as they might be, and, in fact, they regard a rise of the eosinophilia as of good prognosis, while a fall is bad.

There was in this case no epigastric pain. This is a gnawing discomfort which patients seek to relieve by eating earth or coffee grounds or by chewing tobacco or gum (resin); indeed, in the Southern States of America doctors are said (Dock and Bass) to recommend tobacco chewing as a remedy.

The case illustrates the difficulty of successful treatment, for although the patient has taken remedies at intervals on an average of 14 days during the last five months ova are still discharged in the fæces, and therefore living females must be present in the bowel. As the worms do not develop in the intestine, the eggs undergoing no change until they reach the external air, and as my patient knows how to take proper precautions to prevent reinfection, I hope that a cure is being slowly reached; his head attacks have ceased entirely, and he maintains the same weight (April 29th, 1913). He is not at work, and has not been since his return to England. I have been disappointed at the small number of worms seen in the stools after each treatment; at no time have I found more than three worms in a single stool.

Owing to the need of a high temperature for the incubation of the eggs there is little fear of their developing in our northern climate except in mines, where the temperature is, of course, higher than on the surface of the land. Happily, so far it is only the Cornish miners that have become infected, and as they keep to their tin mines, and do not migrate to work in coal mines, the disease has not spread beyond Cornwall. If it did, there is no reason for supposing that it would not permanently infect the mining population in England as it has done in Belgium and Germany, and once the disease has become established it is extremely difficult to eradicate. As many of the harbourers of these worms present no symptoms yet are a source of danger by spreading the disease, it would be necessary to examine every individual in a mining population and to put all the infected persons under treatment, isolating them until it was proved that their fæces contained no ova. It is doubtful whether such a radical method of treatment would be practicable; it would certainly be very expensive.

Owing to the grave danger of allowing a carrier of this infection to return to work, the treatment will be continued until the ova disappear from the fæces.

Birmingham.

RADIUM EMANATION THERAPY.[1]

BY DR. W. ENGELMANN.

IN speaking of radium therapy it is best to distinguish between radium therapy in the narrower sense and radium emanation therapy. It is well known that in the former, which may be assumed to be most in vogue in surgery and dermatology, very strong radium preparations are used; the effect is produced by the rays emanating from the radium, the α, β, and γ rays. The effects in question are, therefore, very strong; they resemble those of the X rays of the Roentgen therapy. As examples I may mention the radiating of skin diseases of the most malignant and obstinate type, including even lupus and cancer—in which this treatment is often startlingly successful, and also injections in the case of malignant tumours, and recently in diseases of the hematopoietic system. In these two examples we have at the same time paradigms for the biological effect of the radium salt on the living tissue, which effect is twofold, namely, irritant—i.e., inflammatory and producing hyperæmia—and, secondly, destructive. In the application of radium emanation, the second kind of radium therapy, [illegible] ve a weakened effect. [illegible] o have to deal with [illegible] I wish to speak in this article.

At Kreuznach, formerly known only for its brine mother-lye baths. a certain amount of experience as to the nature of the radium emanation and the manner in which it acts has been acquired during the five years that have elapsed since the systematic practice of radium emanation therapy began; and during these five years the Kreuznach physicians have endeavoured to give themselves and others some [illegible] essays, [illegible] ological [illegible] possess highly radio-active springs, it is also able to prepare very valuable radium solutions out of the residue obtained in the production of mother-lye; it possesses the only radium factory in Germany.

A number of investigations as to the biological effect of the radium emanation have been made and reported, which do not, indeed, yet give any unobjectionable explanation of the clinical results of the radium emanation therapy, but do justify the hope that such an explanation will one day be found. The nearest approach to a solution of the problem seemed to be made during the investigation of the effects of radium emanation on certain body ferments or on processes in the human or animal organism in which, according to the present teaching of science, enzymotic forces must be supposed to play a part. The actuating influence of radium emanation on the pancreatin, the peptic ferment, and the autolytic ferment is known. The explanation of Van der Velden's observation that radium emanation strikingly increases the coagulability of blood may also be that emanation exercises an actuating influence on certain ferments operative in coagulation.

We may assume a similar influence when we hear that Richet was able to promote the fermentation of lactic acid by a slight dose of emanation and to retard it by a stronger one. The same may be said of the fermentation of yeast, in which an exactly similar, partly retarding, partly promoting effect under the influence of different doses of emanation has been observed.

Von Noorden and Falta believed a connexion to exist between these fermentative processes and what they observed of the behaviour of the white blood corpuscles under the influence of radium emanation. In the human subject they found after emanation treatment a rise in the number of the white blood corpuscles and then an increased decay. They concluded that, as the white blood corpuscles were supposed to be the seat of the ferments, such a connexion was possible if the actuation of the ferments was really to be regarded as an essential effect of the radium emanation.

These biological influences at any rate show that the relation of radium emanation to the radium preparation as such somewhat resembles that of a concentrated medicament of very violent physiological effect to a diluted one; in the former very strong, violent biological effects, demanding the utmost caution in determining the dose and in the manner of application; in the latter a weakened effect, allowing us to apply the remedy more fearlessly. In certain circumstances the radium rays destroy the tissue, whereas the radium emanation actuates and promotes the processes in the body. In the same sense the increase of the phagocytosis, recently ascertained by Laqueur, is to be valued. Here, too, the question was of therapeutically applied doses. The fact that radium emanation has a retarding effect on the growth of several kinds of bacteria, including pathogenic ones, or even kills them, has been harmoniously ascertained in several different quarters. It cannot be turned to therapeutic account without more ado, because in the test-tube experiment comparatively high doses were given; but it is biologically interesting. Contrariwise Falta and Schwarz have ascertained by experiments in the field of vegetable physiology that even large doses of emanation may have a furthering effect on a physiological process. Emanation has an intensely furthering influence on the growth of oat germs.

It has also been ascertained by Plesch that the maximum pressure of the blood sinks under the influence of radium emanation, and that in some of the cases examined the medium pressure decreased, so that a diminution of the work done by the heart must be assumed. In many persons emanation increases the gaseous interchange, frequently also the elaboration of albumin. Finally, Kikkoji and Bernstein say they have ascertained an increase of the combustion of sugar.

We see, then, that in many cases the effects of radium emanation in experiments and in practical application run parallel. We find that it has an intensely stimulating effect on all the factors of assimilation, that it enhances, as it were, the vital processes. In this sense also I interpreted the results of a series of experiments which I made two years ago. Originally induced by the favourable effects of radium emanation on sufferers from gout, and following von Logham's example, I produced artificial tophi in rabbits. I injected liquid preparations of uric acid into the subcutaneous connective tissue, and observed the behaviour of the deposits under the influence of emanation. Untreated control animals with the same deposits served as objects of comparison. The slow resorption of the deposits which set in in obedience to physiological laws was quite considerably accelerated under the influence of radium emanation, the effect becoming noticeable within 24 hours. At the time when the experiments were made one might have been tempted to regard this phenomenon as a specific effect on gouty deposits, for at that time Gudzent's experiments had not yet been tested. It is known that Gudzent believed himself to have demonstrated that uric acid is found in the blood as urate of mononatrium, and that in two forms—a stable and a less stable one. Under the influence of emanation he found in the test-tube a transformation of the former form into the latter, and believed that in this phenomenon he had discovered an explanation for the removal of the uric acid from the organism, which is really observed. The experiments have been tested in two quarters and not confirmed. This, as is known, was one of the things that led to the rather vehement discussions of last spring, which somewhat discredited the emanation therapy. Unfortunately, or rather, not quite justifiably, for, firstly, Gudzent's experiments were afterwards confirmed. In Madame Curie's laboratory Mesernitzky, who conducted his investigation somewhat differently, found the same results. He worked, it is true, with very high doses of emanation. The question must be declared at least undecided.

---

[1] A lecture given at a clinical meeting of the Municipal Hospitals at Dortmund.

Secondly, however, the good therapeutic results could not be denied. Finally, the fact that the excretion of uric acid was influenced by emanation remained unshaken. Both Gudzent and Mesernitzky were able to ascertain an increase of the excretion of the endogenous uric acid and purin bases in healthy persons. In the case of sufferers from gout it was ascertained that exogenously introduced material containing purin was promptly excreted under emanation treatment, whereas the previous excretion had been slow. This would give us an idea of the manner in which radium emanation operates if we think of the definition of gout, which tells us that gout is the expression of a pronounced disturbance of the fermentative system of the elaboration of purin, which consists in the retardation of the formation, destruction, and secretion of uric acid, and leads to a permanent accumulation of uric acid in the blood, i.e., to uricæmia.

It is to be noted that the persons on whom Gudzent experimented had inhaled the emanation; they were in the so-called emanatories. Mesernitzky found the same results in the laboratory of the salt works belonging to the town of Kreuznach in patients who drank radium water. I must add, it is true, that these phenomena did not appear in all persons with equal intensity, as, indeed, be it said by way of anticipation, in the emanation therapy it is more than ordinarily *necessary to individualise. The influencing of the blood is* also subject to similar variation. It has been already mentioned that leucocytosis, frequently followed by leucopenia, was ascertained under emanation treatment in von Noorden's clinic. In His's clinic this effect has been ascertained even when the doses were small. My own investigations, it is true, do not confirm this, at least after drink cures. In dogs, on the other hand, when large doses were given, I found, as the Vienna investigators did, quite considerable leucocytosis, which lasted till a fortnight after the last dose. It is true that I gave them doses up to 50,000 units a day (Mache Einheiten); to human beings one gives 1000 to 3000 units (M.E.). In certain forms of diseases those high doses will be more frequently given in future than hitherto. We are reminded in this connexion of the effects of thorium, the sister element of radium, on the hematopoietic system, and of its therapeutic effects in diseases of the blood. It seems to me not impossible that high doses of radium emanation may have a similar effect, but this question has not yet been thoroughly investigated.

A word or two now about the *forms of application*. We administer emanation by means of baths, inhalation, drinking radium emanation water, rinsings out, enemas, or compresses. For a while baths did not enjoy among the radium therapeutists the reputation which they decidedly deserved. Quite unintelligibly, if one considers that at watering-places with waters rich in emanation this form of application has long been one of the most favoured. Löwenthal believed that he had ascertained that emanation, which, as is known, has all the characteristics of a gas, does not penetrate through the skin into the body, and that therefore baths are useless. Even if he had been right, his conclusion was a hasty one, for the agent in question was comparatively unknown, not yet exhaustively studied, and, above all, the possibility of the α, β, and γ rays exercising an influence in the form of induced activity, which precipitates itself on the body on all sides, was left out of account. I may remind the reader that emanation, as already said, is a gas which emanates from radium. It is, as is known, colourless, odourless, tasteless, and is best demonstrable in the air, in springs, and in fluids in general by means of the electroscopic method. Emanation electrifies the air, and thus acts, e.g., on the little plates of an electroscope. The measuring method is extremely simple and should always be applied when clinical observations are made after emanation therapeutic measures. The understanding of its behaviour in the organism is facilitated by remembering that emanation is comparatively short-lived. It disappears within about eight days, disintegrating into solid elements, radium A, B, C, D, &c., which also have a more or less long duration, and emit the biologically effective rays, while they precipitate themselves, if we will conceive it so, on the cells in the organism. Radium emanation water must therefore always be applied as fresh as possible, because otherwise its strength does not correspond to that perhaps ascribed to it.

To return to the baths, I was able three years ago to demonstrate *at Strasburger's clinic in Bonn* that the emanation does indeed penetrate through the skin during a bath, and is demonstrable in the blood. My measurements were afterwards confirmed from another quarter, and the reputation of baths was restored. According to more recent investigations the penetration of emanation into the body seems to be even more considerable than I then supposed. Thus, also, a new justification was given for the application of poultices, which Strasburger had strongly advocated from the outset. There is, it is true, no doubt that the manner of operation is not thereby exhaustively explained. It is not only the emanation that has penetrated into the body that operates, as does also the inhaled emanation; the β and γ rays that penetrate through from without operate too. Perhaps also the α rays, which are, indeed, biologically very effective but do not penetrate so deep, operate by irritating the nerve terminations or the like. To be worthy of the name, a radium bath must have a strength of at least 7000 to 10,000 units (M.E.). Baths containing less than that are *not specifically* effective. The baths given at Kreuznach contain 22,000 units. If necessary, and if patients can stand it, emanation water can be added till the bath has twice or three times that strength or more. The temperature is that of an ordinary bath, and the patient should stay in it as long as possible. Our patients are not allowed to dry themselves, but rest, wrapped in their bathing-sheets, *for 20 to 30 minutes till the emanation dries in, in order to secure the* longest possible duration of its influence.

Another method of conveying the radium emanation into the body is by drinking.

After long controversies the opponents of the drinking method now admit that it is at least not inferior in value to inhalation. It is now admitted on all hands that it was, first and foremost, the Kreuznach doctors who always kept emphasising the effectiveness of the drink cures. The opponents contended that when one drinks emanation water it gets after resorption in the intestine only into the small circulation, and that, owing to its instability, the gaseous emanation is so completely exhaled in the lungs that only infinitesimal quantities get into the great circulation. My above-mentioned experiments, in which I gave the animals 60 grammes of emanation water daily—i.e., 600 units—per os with the œsophageal probang, spoke strongly, in harmony with the numerous clinical observations that had been made not only at Kreuznach but also elsewhere, for the value of stomachic incorporation. Accurate investigations of the blood—i.e., measurements of the blood with a view to ascertaining how much emanation it contained—which had been made in the most various quarters by Strasburger, Lazarus, and others, proved unambiguously that the drinking method is a very rational one. Not less than two years ago I had ascertained in the case of a dog with an intestinal fistula that even an hour after a dose of emanation water the intestinal juice contained about 30 per cent. of the emanation-content of the dose. It follows that the passing of emanation into the blood lasted for at least that length of time. By measurements of the blood of dogs I was then able to ascertain as a fact that emanation is still demonstrable with certainty in the blood *even two hours after drinking*. If, therefore, the patient drinks small quantities of radium emanation water four to six times a day, a lasting loading of the blood with emanation can easily be brought about. And at Kreuznach the method has already stood the test of experience for a long time. In general the patients drink from 1000 to 3000 units (M.E.) a day. Of course one must begin with small doses, and increase them only if the water agrees well with the patient.

The third principal form of application is *inhalation*. The idea of incorporating emanation as gas with the organism by inhalation was obvious. So-called emanatoriums were constructed—little rooms the air of which was loaded with emanation. In these a number of patients could sit, and thus conveniently inhale emanation. Apparatus was provided for the absorption of bad air and the introduction of oxygen. It was believed that during a patient's stay in such a room the incorporated emanation could be rightly retained in the organism. It is possible that the emanatorium treatment thus came to be overrated, especially when Gudgent claimed to have ascertained that during one's stay in such an emanatorium even an enrichment of the blood with emanation took place. If this were the case, there must be an affinity between emanation and blood. There is, however, as Plesch and I were able to demonstrate by joint experiments, no such affinity. The manner in which we experimented even led us to the result that blood takes up about 10 per cent less emanation than water does The above mentioned investigations of the blood by several writers also spoke against the opinion It is, therefore, probable that an enrichment does not take place, though a plentiful loading of the blood, corresponding to the quantity of emanation used, does The stay in emanatoriums is, therefore, very well fitted to bring emanation into the body, and therefore to be therapeutically effective The constructors of emanatoriums have been blamed for bringing only the so called two unit emanatoriums into the market—i e, such as contain two units (M E) per litre of air That is not sufficient, at least for the majority of patients One must be able to demand from eight to ten units Von Noorden complains that they do not adequately meet the necessity of adapting the doses to the requirements of the individual patients He prophesies a greater future for the inhaler designed for only one person It is portable, and can be used by patients who are confined to bed, it is also cheaper, allows one to vary the dose, and does not compel patients to sit together in a little room in which the air is often bad

Along with Professor Bickel I some time ago perfected, tested, and showed to the Medical Society of Berlin such an inhaler intended for one person It is intended to serve as supplementary to any apparatus for the preparation of emanation water—Neumann s activator, for instance In my opinion one is best able to practise rational radium emanation therapy if one uses two such apparatuses, no matter of what system One has the option of giving radium baths, poultices with radium water, rinsings out, enemas, nutrient enemas emanation water to be drunk, and, lastly, emanation to be inhaled with the help of an inhaler intended for the use of one person

We come now to the groups of diseases for which radium emanation therapy is suited, and here the first disease to be named is gout genuine gout, arthritis urica, for which radium emanation seems in many cases to be almost a *specific remedy*

I remind the reader of the above remarks on the influencing of the assimilation of purin The best treatment is that in which all the above mentioned forms of application—drinking, inhalation, baths, compresses if necessary—are cautiously combined If the organism reacts—it is a singular fact that there are not a few cases in which it does not—it frequently happens that *the feeling that it is taking effect soon sets in After from* four to six days the known reactions take place pains in the joints in the most different parts of the body, often as severe

the most part of shorter
in may be given for a
nd the effect slowly sets
in Subjective and objective improvement takes place In contradiction to von Noorden I wish to state that the tophi *do become softer Strasburger and others have also noticed* this The treatment—in cases of necessity a drink cure alone suffices—should last six weeks, and it seems advisable to repeat a drink or inhalation cure once or twice a year, the choice being determined by the remedial resources of the patient's place of residence

Another large field for the advantageous practice of emanation therapy is articular rheumatism in its most various forms, above all the primarily chronic polyarthritis exsudativa and the primarily chronic arthritis sicca, which occurs, I presume, mostly at an advanced age The treatment is the same as that sketched above, but here the use of baths and poultices is very decidedly to be recommended Under certain circumstances the advisability of injecting radium solutions is also to be considered Here, too, there may be slight reactions—pains and sometimes a slight increase of temperature Sciatica, too is a malady in which the treatment is likely to be rewarded by success but owing to the multiformity of its etiology there are of course, unsuitable cases When all other therapeutic measures fail a trial is much to be recommended I have seen cures and many partial cures myself In general the effects on many other disorders of the nervous system are notable This fact is probably connected, as Strasburger points our, with the antiphlogistic and resorption furthering qualities of emanation Moreover von Knaffel Lenz, of Vienna professes to have ascertained by experiment that the healthy nerve tissue is influenced by emanation All kinds of neuritis and neuralgia are suitable objects of treatment Here, too, besides drink and inhalation cures baths and compresses play a great part The effect of the latter, e g, is often subjectively ascertainable immediately after application, often diagreeably at first I have seen two extremely obstinate cases of herpes zoster in persons fairly advanced in years which had defied every kind of treatment, quite surprisingly bettered These are only instances among many The lancinating pains of sufferers from tabes dorsalis are relieved Then there is the myalgia group Besides all these, I mention also bronchial asthma, presclerosis, arterio sclerosis, and diseases of the genitals of women, especially in cases in which it is important to assist the resorption of chronic exudates, swellings of tissue, and the like And, in general, adhesions, tissue thickenings of every kind formation of callus, formations of scars cannot be otherwise than favourably influenced by a combined local and general emanation treatment Advantageous results after radiation with radium preparations in cases of myoma and disturbance in menstruation have quite recently been reported from the Freiburg clinic for women In these cases the radiation with radium rays took the place of radiation with Roentgen rays It seems to me not impossible that the somewhat milder application of these rays practised in radium emanation therapy will in future play a more important part in the treatment of women The experience gained at Kreuznach, where female patients are very numerous, speaks strongly for this opinion. But the decisive, quite objective observations cannot be made at a watering place At any rate, a histologically demonstrable influencing of the ovaries and also the occurrence of miscarriage after mere drinking of emanation water have already been experimentally ascertained By means of poultices, rinsings out, and, above all, nutrient enemas, the use of which is already very frequent at Kreuznach, it will also be possible to render the general radium treatment of the diseases of women very powerful local support

The skin diseases belong in general to the province of radium therapy in the narrower sense—i e, they must be treated by radiation with radium preparations In many obstinate cases, however radium emanation also may well deserve to be recommended I will not enumerate all the maladies for which the emanation treatment is suitable, but only mention some cases of cured or very considerably bettered scleroderma reported in the literature of the subject One such case I saw myself So far as I am aware such cases defy every other treatment

I do not mean to say that the treatment in question is, as a matter of course, the only right treatment for all the phenomena of disease which I have somewhat copiously enumerated, but only that in suitable cases it is reasonable and worth while to try it After all, this therapy is still young, and it is possible that our views as to the question what diseases it is suitable for may undergo considerable modification Von Noorden thinks it is applicable to still more diseases than I have mentioned He believes, for example, that attempts to cure corpulence on the lines of
the abov
ment of
of succe
stomach he thinks the same, he has seen good results in cases of nervous gastritis A fellow doctor drew my attention to the fact that his achylia gastrica, which had greatly impaired his health and defied all treatment had so considerably improved after a drink cure that he now, months afterwards, felt better than ever I believe that strictly clinically conducted experiments in this direction will not fail to be rewarded

Finally, I mention the effect of emanation on the power of generation The observations come from the most various quarters, above all from von Noorden and from doctors at Joachimsthal and Kreuznach The phenomenon would harmonise very well with the results of O Hertwig s investigations, who ascertained a quite specific effect of the radium rays on the nuclear substances of the two sexual cells, and with the observations of Halben, who succeeded in enhancing the secondary symptoms of sexual passion in water newts by radium emanation Affection of the kidneys tendency to bleeding, and tendency to miscarriage
contra indications
enumerations which, owing
at my disposal, cannot be

complete, and which aim only at giving a general idea of the nature of radium emanation therapy. I believe one need not be too much of an optimist to be able to endorse von Noorden's declaration that radium emanation therapy may now be justly regarded as belonging to the solid stock of medical therapeutic measures.

Bad Kreuznach.

THE USE OF TUBERCULIN IN DIAGNOSIS AND TREATMENT.[1]

BY J. F. HALLS DALLY, M.A., M.D. CANTAB., M.R.C.P. LOND.,

PHYSICIAN, AND PHYSICIAN IN CHARGE OF THE SPECIAL DEPARTMENT
FOR TUBERCULOSIS, TO THE ST. MARYLEBONE GENERAL
DISPENSARY; SENIOR ASSISTANT PHYSICIAN TO THE
NATIONAL HOSPITAL FOR DISEASES OF
THE HEART.

Tuberculin in diagnosis. The specific tuberculin tests are four in number: (1) the ocular reaction of Wolff-Eisner and Calmette; (2) the cutaneous reaction of von Pirquet; (3) the percutaneous reaction of Moro; and (4) the subcutaneous reaction of Koch. All the above tests have their appropriate individual uses. They depend on the existence of that "paradox reaction" termed anaphylaxis.

1. Calmette's ocular reaction, described in 1907, has since then attracted considerable attention. Many precautions are necessary in its application, and, even so, the test is not without a certain measure of risk to the eye, so that both for this reason and because, moreover, it is not as sensitive as the other three tests I have mentioned, it has now largely fallen into disuse in general medicine.

2. Von Pirquet's cutaneous reaction. The chief value of this reaction appears to be in the case of children under 5 years of age, where a positive reaction may be taken to indicate the presence of definite tuberculosis. In adolescents and adults a positive result must be reviewed in conjunction with all other available data before an opinion be given.

3. Moro's percutaneous reaction is a modified von Pirquet's reaction, and is readily performed by rubbing into a small portion of the skin an ointment of equal parts of old tuberculin and anhydrous lanolin. Occurrence of a localised dermatitis denotes a positive reaction. The ease and safety of this test are its chief advantages.

4. Koch's subcutaneous test is necessarily preceded by the patient's temperature being recorded three-hourly for at least three days before the injection, since this test should only be applied if the temperature is below 99° F. For adults the first test dose consists of 0·001 c.c. old tuberculin (O.T.). If no reaction ensues 0·005 c.c. O.T. is given in three days, and if still negative 0·01 c.c. O.T. at a like interval of time. In the continued absence of reactions one may say that no tuberculosis is present. For children over about 10 years of age the diagnostic dose may often be equivalent to that for adults, but for a child of 5 years of age the initial dose should not exceed 0·0005 c.c. O.T. and the next subsequent dose 0·0025 c.c. O.T.

The complete and typical reaction which may be expected, if tuberculosis is present, is in nature tripartite—viz., focal, local, and general, these manifestations being given in the order of importance. The focal reaction is essentially specific and produces hyperaemia and inflammatory swelling around the tuberculous focus, this in the lung being evidenced by the presence of new or increased moist crepitations in the affected patch, and appearance or increase of tubercle bacilli and elastic fibres in the sputum, which may be, and often is, itself increased in quantity. I regard the focal reaction as by far the most definite and conclusive of the three. Next comes the local reaction at the point of injection, which gives similar clinical appearances (apart from the papule) to the von Pirquet reaction. The general reaction is shown by fever and consequent malaise, &c. A rise of 1° F. or more may be regarded as positive, and this comes on about 8 to 12 hours after the injection, appearing usually on the temperature chart as a peak with sharp elevation and decline, the downward slope at times being interrupted by a second rise usually of lower, but occasionally of higher, level than the first.

Of all the diagnostic tests the subcutaneous one is, in my experience, the most reliable. If no tuberculosis is present tuberculin has no ill-effects. This fact alone encourages one to use tuberculin at the earliest moment to pick out cases suitable for sanatorium and tuberculin treatment from those for which these remedial methods are either inadvisable or unnecessary.

Tuberculin in treatment. In the brief space at my disposal I cannot hope to do more than touch upon a few salient points based upon clinical observation in my tuberculosis department. The preparations of tuberculin are many and various. I find that some patients are more sensitive to one form of tuberculin and less sensitive to another, so that if intolerance of one kind of tuberculin is manifested it is wise to make a change. The main point to remember is that, no matter what preparation is used, sufficient time must be allowed for proper spacing of doses, and that it is never good policy to attempt to proceed too rapidly. If the remedy is to be beneficial, I believe that throughout one should try to avoid all but slight reactions, the only exception being in early stages of the weak preparations, where hypersensitiveness can be overcome by cautious increase of dosage at comparatively short intervals. This has the effect of inducing tolerance to the successive stronger doses, whereas repetition of the same or smaller doses at longer intervals appears to produce, and, if present, to intensify, that very condition of extreme sensitiveness which one is so anxious to avoid. Hence under such conditions one's motto must be, "Vestigia nulla retrorsum." Should, however, such procedure fail, the only course is to suspend the treatment for some weeks.

As to the *scale of dosage* which should be adopted there is no hard-and-fast rule. It is impossible briefly to give a set scale to which one should work, for not only has one to deal with each individual patient as a separate problem, but also to be guided by the ever-varying factors of the patient's sensitiveness in particular and of his state in general. In my own practice I have abandoned other methods for the intensive system of dosage. In the treatment of pulmonary tuberculosis I begin with small doses of a weak bovine preparation e.g., 1/10000 c.c. or less of P.T.O., and working through increasing doses of this to bovine old tuberculin (P.T.). I complete the treatment in all cases wh [illegible] course of human tuberculin, usually O.T. [illegible] tuberculin (T.A.F.), finishing with doses of 1 c.c. or even more at longer intervals. In the earlier stages of treatment my custom is to inject every three or four days, and when larger doses of the strong preparations are reached, once a week.

Since the administrator cannot, with any accuracy, check the number of milligrammes of solid active substance contained in the particular preparation used, I invariably record dosage in terms of cubic centimetres, for one can always measure exactly the amount of fluid that one injects. Tuberculin, when diluted, soon becomes inert, so that fresh dilutions should be made at least once a week. I nearly always make the dilution with freshly prepared saline solution containing 0·5 per cent. phenol at the time of administration. This procedure takes a little longer, but one thus avoids severe reactions consequent upon a potent dose following one which has been inactive.

On these lines immunisation can usually be attained within from 4 to 12 months, and various statistics show that such immunisation is capable of persisting over a period of several years.

In cases which are doing well the dosage can be increased more rapidly, so that the total time of immunisation is thus shortened. In advanced cases tuberculin does good at times in checking the rapid onward march of the disease, and the temperature may be brought to normal with apparent amelioration of physical signs to percussion and auscultation. Other cases, again, do badly. X ray examination in both these classes not infrequently reveals increase in shadow in the lungs, but in a case doing well in other respects it would be hard to say that such increased opacity represents extension of disease, since augmentation of visible shadow may quite well be due to attempt at repair by fibrosis. Should the disease progress notwithstanding cautious injections, tuberculin should be discontinued.

Lower Seymour street, W.

[1] Abstract of a paper read at a meeting of the Chelsea Clinical Society on April 15th, 1913.

THE TREATMENT OF CONFIRMED CASES OF HIGH BLOOD PRESSURE

THE UNDESIRABILITY OF ACTIVELY APPLYING THERAPEUTIC MEANS TO REDUCE IT[1]

By ALFRED MANTLE M D Durh , M R C P Lond ,
CONSULTING PHYSICIAN TO THE HALIFAX ROYAL INFIRMARY

THE instrumental estimation of blood pressure is comparatively new in the investigation of disease, and without doubt it has been very helpful in the treatment of certain cases But whilst the sphygmomanometer gives us a reading which forms a good working basis in treatment, readings must not always be considered as representing the exact measurement of blood pressure for in certain circumstances particularly when the subject is emotional or unduly anxious, the readings may be higher than they should be, and this we should allow for to some extent It is rather more than a year ago—when I opened a discussion at the Leeds Medico Chirurgical Society on some aspects of high blood pressure requiring special consideration in treatment—that I particularly pointed out that in some cases increased pressure remained high whatever measures were taken to lower it, and that it was wrong treatment to press vasodilator remedies in such circumstances

It has been one of the unfortunate by products of our recently acquired ability to determine a patient's blood pressure in millimetres of mercury that the sight of the column near the top of the tube has so often led to immediate endeavours to reduce the pressure at any cost (Janeway) This point is not sufficiently recognised by some practitioners who make use of the instrument, and I get cases of high blood pressure sent to me at Harrogate for special treatment to reduce it, in which nitrites, large doses of iodide of potassium, and other depressing remedies have been used, with the story that the pressure will only partially yield to treatment The fact is that owing to the gradual increase of blood pressure each individual readjusts his cardiovascular physiology to compensate this, and the physiological limit is now not 140 or 150 mm Hg, but may be 220 or 250, and to reduce the pressure below this new physiological limit is not only not indicated, but is bad therapy "The fact should be emphasised that supernormal arterial pressure is not itself a primary condition to be attacked or controlled as such It is invariably a result of some pathological cause or causes, and it is moreover, often a necessary evil the result of conditions we cannot remove, and then it must be looked upon as a compensatory effort, as one of the natural defences of the body" (Oliver)

A patient, aged 65 was referred to me two years ago as having had a high blood pressure for some years, and he had had considerable therapeutic attention paid to it He had been a great athlete and rowed in his University boat three years When I saw him the pressure showed a reading of 180 mm Hg, and he was dyspnœic on exertion His heart was enlarged, the apex beat 1' inches outside the nipple line with very irregular action There was no albuminuria and the vessels were not palpably thickened It was clear that the compensatory hypertrophy which had helped him so long was failing I gave him no lowering treatment, but that which was directed to the raising of his pressure, and advised moderate exercise with plenty of rest between I gave him strophanthus and nux vomica to raise his pressure, and he had Nauheim baths and Schott exercises to open out his peripheral circulation, which was contracted After three weeks' treatment his blood pressure was 15 mm higher and the heart more regular, and he returned home much better He made another visit last year, having taken strophanthus as required under the directions of his medical man in the interim, and his blood pressure was in a still more satisfactory condition, for it was steady at 200 mm Hg, and he was able to do his ordinary amount of walking exercise quite comfortably This was plainly a case where it was wrong to deprive the patient of a [illegible]

220 mm Hg, and with the exception of occasional slight giddy attacks after prolonged exertion he suffered no serious symptoms The heart's apex was very little out of its normal position and his kidneys apparently were good He had had constipation for years and the sphincter ani had been stretched to relieve it I therefore gave him a little intestinal lavation, but it was not found necessary to do so after a few douches His pressure was down to 200 mm after this treatment and some massage douche baths, but I heard from his medical man that it was soon back again to 220 mm He had been given 20 gr doses of iodide of potassium to reduce the pressure for a considerable time, but with no marked result except to mentally depress him My advice to him has been to live a healthy life, avoiding alcohol red meat and salt, to take aperients for the constipation, and exercise, and leave the iodide and other depressants alone I have recently heard from him that he is keeping well, and is continuing his *régime*

The following case is an extreme example of a class not uncommonly met with high blood pressure, with some cardiac hypertrophy, and symptoms for years referable to a certain amount of disturbance of the liver and bowels in the middle aged, who show no signs of arteriosclerosis in the systemic periphery, and no clinical evidence of nephritis after examination for albumin and casts Sir Clifford Allbutt has called attention to these cases, and he names them hyperpiesis It is a curable condition if caught early, but if not it frequently ends in a permanently high pressure, and possibly in apoplexy, or cardiac defeat in trying to overcome the supernormal pressure

A medical man, aged 58, was sent three years ago for Harrogate treatment He had been seen by two physicians in a northern city who thought the symptoms I am about to describe due to the development of some cerebral disease The patient had taken a fair amount of alcohol, but none for the five years previous to his illness, but he had been a big eater of red meat He worked hard in a country practice and was subject to bad headaches, for which he frequently took calomel and antipyrin He had, however, what he called a seizure, which he described as being constituted by great pain and throbbing in the head and marked giddiness in the erect posture I was asked to see him in consultation with Dr Gordon Black some weeks after this attack He was very emotional, and was rather like a candidate for cerebral softening He complained of throbbing in the head, and was more or less giddy in the erect posture On examination the pulse was one of very high pressure to the touch, and the sphygmomanometer showed a systolic pressure of 220 mm Hg As is my custom, I looked for corroboration of this in the position of the heart's apex, which was a full inch outside the nipple line There was no albumin, and the urine was of good specific gravity We came to the conclusion that the symptoms were due to the high blood pressure, and that the only possible chance for the patient was to give him perfect rest with a very strict diet All meat was forbidden as well as salt He continued to have nothing but milk and fish for the three or four months whilst under our care He was well purged and the skin was kept active, but he was much too ill to have any balneological treatment The blood pressure gradually came down and the apex beat came in, and after four months' rest he was able to walk fairly comfortably without much throbbing or pulsation The patient eventually got back to his work, and continues well He lives practically on the same lines of diet, taking no red meat or alcohol, and is now able to do as hard a day's work as he ever did, and when visiting Harrogate last year we found his pressure 140 to 145 mm Hg only

This is an instance of what can be done for some cases of high blood pressure in the way of treatment when seen early This patient had no nitrites after the first week's treatment, for they had no effect in reducing the pressure, neither did he have iodides, and we may attribute his recovery to rest, alteration in diet, and more or less free purgation with calomel and salines

A natural question to ask is, How are we to determine the true position of a case of supernormal pressure? These cases always give us anxiety, and rightly so, for we are confronted with two dangers and with one eye we see visions of a possible catastrophe through the rupture of a weak vessel by doing too little and with the other the danger of doing too much in lowering the pressure and weakening the cardiac force My reply to this is take a careful history of the case and observe the condition of the cardiovascular, the renal and alimentary systems and try find out the cause of the high pressure, such as errors in diet, alcohol, syphilis, lead, and excessive worry, remembering that supernormal pressure is not a disease *per se*, but a symptom only. If the left ventricle is hypertrophied it suggests the pressure has been persistently high for some months or years. Experience teaches us that with a restriction of red meats and alcoholic drinks from the dietary of those who take them freely the pressure, if not a permanently high one, usually diminishes, and this argues that purin bodies and alcohol probably act as vasoconstrictors. Waste is constantly going on in the body, and it is important to get rid of the products of waste whatever they may be The proof of the splanchnic vessels being some of the earliest to become affected in arteriosclerosis points to our relieving congestion of the visceral vessels, which can be done by judicious purgation, and 1 gr. doses of calomel and saline purgatives are most useful two or three times a week. One of the greatest outlets for waste products is the skin, and when inactive a free action of this organ must be encouraged by artificial means, such as by massage-douche and Nauheim baths, when these can be obtained, and intestinal lavation is also very desirable in cases with constipation. It is a common observation that with a dilated periphery causing an active skin we have a lower range of blood pressure, which leads us to suggest to those who can afford it to follow the sun. The cardinal principles of treatment, then, resolve themselves into a strict regulation of the intake and an active outlet for the waste products, and moderate exercise followed by rest is very desirable to give a better distribution of the blood. In all cases observations must be made with the sphygmomanometer from time to time as a guidance in treatment.

---

[1] A paper read before the Balneological Section of the Royal Society of Medicine on April 14th 1913.

If in spite of our *régime* and treatment the pressure continues high after having watched the case carefully for some months, we conclude that this is a case in which the pressure is permanently supernormal. In any case, we recommend the general *régime* to be continued, and so long as no urgent symptoms arise the patient may do his work in life if he avoids excitement and sudden strain. Lastly, we must not use any *active* means to reduce the pressure, remembering that it is probably an advantage and necessary that the pressure should be high for the maintenance of an adequate supply of blood to vital organs. As for drugs of the vasodilator type, I mean the nitrite group, I use them very little except in emergencies, for I believe it is sounder treatment to get rid of the bodies in the system which contract the periphery by the means I have mentioned, rather than by dilating up the blood-vessels with the offending poisons still intact. I give iodides very carefully, if at all, but if there is any syphilitic history they may be pushed. As for gypsin, this I have given a trial in some cases, but with no marked results.

Harrogate.

PROTOZOAL-LIKE STRUCTURES IN THE BLOOD IN A CASE OF BLACKWATER FEVER.

BY ALFRED C. COLES, M.D., D.SC. EDIN., F.R.S.E., M.R.C.P. LOND.,
BACTERIOLOGIST, ROYAL VICTORIA HOSPITAL, BOURNEMOUTH.

THE cause of blackwater fever still remains one of the most important problems unsolved in tropical pathology. A friend of mine, aged 28 years, who had never had an attack of blackwater fever, arrived in England on Dec. 23rd, 1911. He had resided in Rhodesia for four years and had enjoyed comparatively good health. On Dec. 27th, after a dance, he passed blood-stained urine, and shortly afterwards had rigors, bilious vomiting, and a temperature of 104·2° F. He passed through an acute attack of blackwater fever. The urine on the fifth day became quite normal, but he collapsed, sank into a comatose condition, and died on the sixth day. Throughout my attendance upon him I took numerous blood films and fresh cover-glass preparations. The films were stained with Leishman's stain, or with Leishman's first and then with Giemsa, or fixed in absolute alcohol and stained in the usual way with Giemsa's stain. The fresh preparations were examined very shortly after they were made by ordinary and by dark-ground illumination.

Examination of the Blood.

No enumeration of the cellular elements was made during this short illness, and the hæmoglobin was only estimated once, on the last day, when it proved to be 14 per cent. The following tabulated statement shows the percentage of the leucocytes during the illness :—

—	Dec. 27th, 1911. 12 noon.	28th, 12 noon.	28th, 6 P.M.	29th, 12 noon.	30th, 12 noon.	31st, 12 noon.	Jan. 2nd, 1912. 3 P.M.
	%	%	%	%	%	%	%
Polymorphonuclear ...	74	68	65	63	61	64	47
Lymphocytes...	12	19	21	10	15	14	20
Large lymphocytes ...	12	12	13·5	27	23	20	28
Eosinophiles	2	1	0·5	0	0	0 5	1
Myelocytes	0	0	0	0	1	1·5	4

The leucocytes were apparently about normal in number during the first three days. Thereafter they increased, and on the last day on which films were taken there was a very pronounced leucocytosis. Some few of the leucocytes contained small vacuoles in their protoplasm on the first day of the fever, a condition not uncommonly met with in several pathological states of the blood. In addition to these, one or more large vacuoles, as large in some cases as a red blood corpuscle, were not infrequently seen, especially in the last stage of the disease, and two or three most perfect examples of leucocytes containing a red corpuscle in their interior were found. One of these erythrophagocytic leucocytes was a polynuclear, the other a transitional form of white cell. The red blood corpuscles were in the first stages of the fever fairly normal in size, shape, and staining reaction, and remained more or less so till about the fourth day of fever, when moderate signs of anæmia became evident and a few nucleated red corpuscles were found. Basophilic and polychromatophilic [illegible] corpuscles, although occasionally seen, [illegible] this stage. On the last day (Jan. 2nd), however, when the hæmoglobin had fallen as low as 14 per cent., all signs of degeneration alterations in red corpuscles were abundantly evident, and the blood picture was not at all unlike that seen in advanced pernicious anæmia, with the exception of the marked leucocytosis. A very conspicuous feature now was the large number of nucleated red blood corpuscles of all sizes, many showing signs of mitotic division. Whilst counting in the stained films 100 leucocytes I met with no less than 16 nucleated red corpuscles of various sizes.

So-called ring bodies described by Cabot and others were numerous in the films taken on the last day. Red blood corpuscles, often showing pholychromatophilic degeneration, were seen containing red stained rings in the form of complete circles, figures of 8, or other weird shapes. These are commonly met with in many forms of severe anæmia Free rings straightened out into threads, and staining a deep red with Giemsa's stain, were commonly seen. But what I had not previously observed in other severe anæmias was the presence of long threads of a deep red colour entering into or coming out of the bodies of lymphocytes or nucleated red corpuscles. One in particular I photographed. I should think it was a nucleated red cell having a diameter of 12μ, with a nucleus measuring 7μ. Running into this or from it was a deeply red-stained thread thicker in the middle, measuring 39μ in length, of which the part outside the cell measured 26μ, whilst the remaining length which was coiled within the protoplasm of the cell was 13μ long.

Special attention was directed to the red cells in the early stages, and every attempt was made to try to find any bodies within their interior of the nature of piroplasms. In not a few red cells specks of stained substance were found, lying for the most part towards the margin of the corpuscle. These, when examined with the highest power available (about × 3000), were seen to consist of small round-shaped dots often connected together by a very fine filament. They stain with Giemsa a dark dirty red colour, and not a distinct red as chromatin generally does. My friend Mr. E. M. Nelson kindly examined some films and recognised these intra-corpuscular bodies, but naturally was not able to express any opinion on their nature. He very kindly took some micro photographs of these structures at a direct magnification of 3000 diameters. I cannot lay much stress on the importance of such minute structures, but the fact that they were visible in the corpuscles in air dried films before being subjected to any staining excludes the possibility of their being of the nature of a deposit or precipitate of stain on the surface of the corpuscle. I should add that they were most easily detected in dry unstained films when examined by dark-ground illumination, but this fact does not preclude the possibility of their being degeneration changes in the red cell.

Very prolonged and repeated examinations extending over several weeks were made of the numerous films of blood taken at all stages of this attack of blackwater fever, and as a result I would state that no form of malarial parasites or pigmented leucocytes was ever seen in the fresh preparations or in about 40 stained films most carefully and exhaustively examined.

Repeated examination of fresh cover-glass preparations both with ordinary and with dark-ground illumination failed to show anything moving in the plasma of the nature [illegible] chæta. Stained films gave the [illegible]

[illegible] *red-stained structures.*—In some of the blood films taken towards the latter stages of the disease *a few peculiar granular bodies were found. The* earliest period at which one of these was seen was the fourth day of fever, and then only a single example was found, but they were more frequent on the last day. These bodies were only found after a careful search and were always exceedingly rare. In nine films only 36 such structures were detected, giving an average of 4 per film, which was about ¾ in. square. In some preparations only one granular body was found, whilst in another film as many as 17 were noted. They were not found in any of the films taken during the first four days.

In shape these bodies are nearly always spherical, sometimes oval, and very rarely somewhat irregular in outline. They have a very definite outline, and often a thick capsule or membrane seems to surround them. (See illustration.) The protoplasm stains usually a pale blue colour, sometimes a deeper blue, at other times a bluish-red tint.

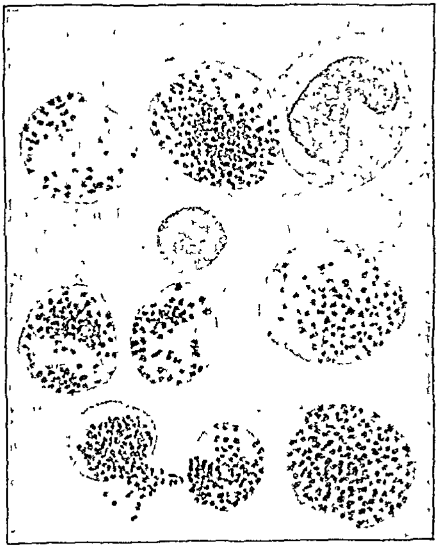
These granular bodies varied in size. The average measurement of 30 specimens was 11·2μ in the longer and 10·7μ in the shorter diameter. The smallest typical example was round and measured 5μ; the largest was oval and measured 17μ by 10μ in diameter. They do not contain a nucleus such as would be seen in a leucocyte, but contained within the protoplasm is a number of small round or oval dots which stain a deep chromatin red colour. These small structures are generally spread irregularly over the protoplasm of the cell, and are often more numerous in the centre than at the margins. The number of chromatin-stained bodies contained within one cell varies considerably, but probably there may be as few as 40 or as many as 200. In most specimens these chromatin dots are situated in a small unstained area, or each dot is surrounded by a narrow ring of faintly stained structure.

These minute intra-corpuscular bodies have a very vague outline, but when examined with the highest powers appear to consist of a dot of chromatin surrounded by a small amount of protoplasm They appear round or oval and measure about 0·3μ to 0·75μ in diameter. Somewhat larger ones are seen oval or rod-shaped measuring 0·8μ by 0·4μ. Sometimes the chromatin dot has a tail of protoplasm and the whole body resembles that of a minute tadpole. Similar bodies are met with in the protoplasm of a few very large mononuclear leucocytes.

What is the nature of these granular blue bodies containing red stained structures? The fact that they were only found towards the end of the disease when the blood was very rapidly becoming anæmic, and that they were then associated with the presence of nucleated red blood cor- [illegible] negative this theory.

The second possibility is that they might represent some form of leucocyte, such as mast-myelocyte or myeloblasts of Ehrlich and Naegeli. Against this view is the fact that they possess no nucleus; that they do not in the slightest degree resemble any of the coloured plates given by Ehrlich and Lazarus of the pathological forms of leucocytes just mentioned; and that during a prolonged period—some 20 years —in which I have been engaged in examining blood from various pathological conditions, notably the various forms of leucocythæmia, pernicious anæmia, aplastic anæmia, &c., I have never met any structures that have the slightest resemblance to these bodies.

Assuming, therefore, that these peculiar bodies do not represent any altered form of the cellular elements of the body, are they of the nature of protozoa? Are they related at all to those structures known as Koch's blue bodies, or do they belong to that vague family of cell inclusions, the chlamydozoa? Koch's granules, blue bodies, or Koch's plasma kugeln are circular, oval, or somewhat irregularly shaped cells which stain by Giemsa a blue colour and are filled with coarse chromatin granules They have been *proved by Gonder to represent certain stages in the life* cycle of Theilera parva, the parasite of East Coast fever in cattle Gonder states that on an average the agamonts measure about 10 to 12μ, rarely 12 to 15μ These structures are found in the internal organs of animals suffering from East Coast fever and a disease affecting calves in Uganda called by the natives Amakebe. They are seen in the spleen, lymphatic glands, bone marrow, and liver, but shortly before death they may sometimes be found in the circulating blood.



Blue stained granular bodies with red stained structures in their interior From a blood film preparation fixed with osmic vapour and absolute *alcohol, and stained with Giemsa.* Drawn with Zeiss' camera lucida Note the variation in size and the different number of red stained structures contained within each A granular body bursting and discharging its contents is seen at the lower left margin A leucocyte and red blood corpuscle are drawn to show relative sizes of the granular bodies.

I find that the granular bodies that I have met with in the blood of this case of blackwater fever have some resemblance to Koch's bodies, but the chromatin granules in the latter are larger, more distinctly seen, and almost always more circular than the somewhat similar bodies I have described.

Against the theory of the relationship of the granular bodies to Koch's blue bodies is the fact that they were not associated with the presence of any definite piroplasms, unless the exceedingly small and ill-defined bodies which I have described in some of the red cells be regarded as of this nature. On the other hand, it is possible that these peculiar bodies are of the nature of the chlamydozoa of Prowazek, a class of vague "organisms believed to be the cause of certain diseases of man and animals."

In conclusion, I would point out that possibly the peculiar granular bodies found in such small numbers in the circulating blood may be present in large numbers in the internal organs of cases of blackwater fever, and that they only reach the peripheral blood at the end of life. I would, therefore, suggest that those observers who come in contact with numerous cases of blackwater fever should examine smear preparations obtained during life by puncturing and aspirating a lymphatic gland, and in fatal cases have smears made from the spleen, bone marrow, lymphatic glands, and liver, to see whether analogous bodies can be found.

Bournemouth.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SPECIAL MEETING OF FELLOWS.

Continued Discussion on Alimentary Toxæmia.[1]

A MEETING of the Fellows of the society was held on April 28th, Sir FRANCIS H. CHAMPNEYS, the President, being in the chair.

Dr. WILLIAM HUNTER, re-opening the discussion, said that the subject matters of the discussion practically covered the whole series of processes which had been the special subject of his interest and investigations during the past 30 years. In the course of his studies relating to the nature of "pernicious anæmia" he had practically spent the greater part of his time in exploring in all their depths the muddy waters of the intestinal processes now brought under review. As the first and most important outcome he was enabled after three years experimental and pathological work to trace back this great anæmic disease to destructive (hæmolytic) changes affecting the blood in the portal system, induced by some special hæmolytic poison reaching it from the intestinal tract. These studies had founded and formed the basis of what had come to be termed "the doctrine of the enterogenous origin of severe anæmias," or "the toxic hypothesis" of the origin of these anæmias associated with his name and work. But although termed a "doctrine" or "hypothesis" his own work was an actual interpretation of the facts which he had ascertained experimentally—viz., that the blood changes of the disease he was studying could only be produced by special poisons which he employed. Further investigations as to the site of the lesions and the source of the infection which produced these particular hæmolytic toxins led him eventually step by step from the intestine to the stomach and finally to the tongue and to the discovery in these three organs of the infective lesions which always underlay this grave and mysterious disease. But they had also led him for the first time to recognise the far-reaching importance of the glaring septic lesions in the mouth—termed by him "oral sepsis"—as the greatest cause of infective disease in the body, and the chief cause of most of the disturbances in the alimentary tract, generally classed as toxæmic. Whatever rôle toxæmia—apart from lesions of the gastro-intestinal mucosa—played, either in health or disease, from an etiological, pathological, clinical, and practical point of view it was much more important to recognise that definite infective lesions, which were easily recognisable and in many cases could be easily dealt with, underlay nine-tenths of the disturbances of the alimentary tract which were termed "toxæmic." Dr. Hunter proposed, as his chief contribution to the day's discussion, to show by means of the epidiascope all sorts and sizes of oral streptococcal sepsis, which he would designate "the shark of the intestinal tract," and the multiple effects which it produced not only in that tract but elsewhere. He hoped he would thereby make it clear that to describe such gross and obviously septic lesions of the mouth as he then showed under the euphemistic and belittling title of "toxæmia" was as illuminating and as helpful as if one applied the term "toxæmic" to a foul septic knife or sponge. The sharpest and broadest distinctions existed and should be drawn between processes in the mouth and processes in the gastro-intestinal tract in relation to the subject of "intestinal toxæmia or auto-intoxication." The mouth processes were not toxic in their character; if they had been so Nature would have provided for it by connecting up the mouth with the portal circulation. The toxicity of the gastro-intestinal processes, on the other hand, was a great physiological fact. The portal blood was always toxic even in health; the liver was the great antitoxic and excretory organ of the portal circulation just as the kidney was the great excretory organ of the general circulation. This toxicity was not an accident, nor did it depend on any one product of gastric or intestinal digestion. All attempts to connect it with any such product had, in his opinion, been futile. Far more conclusive evidence of the natural toxicity of the portal blood was presented every day in the facts of disease—in the disturbances connected with inefficient activity or actual disease of the liver. The most common evidences of portal toxicity were, in his judgment, those presented daily in surgical practice in the phenomena of the sickness, vomiting, headache, and sense of illness following the administration of anæsthetics, more particularly after prolonged administration. These were not due to the poisonous action of the anæsthetic *per se* on the nervous system, nor yet to the presence of food in the stomach or intestine; they were the direct result of the depressed activity of the liver cells induced by the anæsthetic and the consequent imperfect detoxication of the portal blood passing through the liver. If the energy of the liver cell (already depressed by disease and intensely aggravated by the unsound clinical practice of withholding food unduly from the patient prior to operation) completely failed, it became in consequence the victim of its own digestive ferments and its own self-digestion with resulting acute fatty degeneration and acute necrosis. The portal blood passed unchanged into the general systemic blood, producing the fulminating toxic disturbances of continuous sickness, vomiting, hæmatemesis, delirium, and coma, which characterised post-chloroform poisoning. Precisely the same phenomena producible experimentally (in Eck's fistula) by connecting up the portal vein directly with the inferior vena cava. He divided the causes of portal toxicity in health and disease into two classes—(1) non-infective causes, the various products of digestion formed by the ferments of the gastric, pancreatic, and intestinal digestion; and (2) infective causes, the various products formed by the action of bacteria on the food products, which were far more important as a cause of natural portal toxæmia. In health the chief and most abundant were those of the coli group. The degree of putrefaction varied according to the amount of proteid in the food, on the one side, and according to the abundance of coli on the other. The provision made by nature for due regulation of the latter was: first, the daily removal of the mass of excrement, alike of food and of organism in the fæces; and secondly, the provision of protective mucus which lined the whole gastro-intestinal tract, and of protective muscular movements which kept the whole gastro-intestinal contents in more or less continuous movement. In short, they were being continuously "moved on." Chronic constipation was therefore a highly unnatural condition and always a source of increased portal toxæmia. That it might exist in certain individuals as an almost permanent condition without apparently causing ill-health was solely due to the power and protective action of the liver. It was not any evidence of the comparative harmlessness of constipation *per se*, but only an evidence that some individuals possessed the cæcum and colon of an ox with the liver of a pig, capable of doing any amount of detoxication. The influence of the lactic acid group of organism in modifying the character and lessening the degree of putrefactive changes in the intestine was great and important. It had been investigated by him both by experiment and by clinical studies some 25 years ago, and recorded by him before the Royal Society (1890). The lactic acid group were the least harmful and most beneficent group of organisms in the alimentary tract There were therefore, in his opinion, absolutely sound physiological, pathological, and clinical grounds for the use of sour milk in conditions of intestinal putrefaction The third group of organisms present in the alimentary tract in health was the streptococcal group It was always present, but little obvious in health, and probably playing nothing but a saprophytic part in the intestinal processes But in the light of his experience it played an altogether different and mightily important part in disease It was responsible more than all the other normal organisms of the alimentary tract for the various disturbances and lesions of that tract which underlay the clinical conditions generally termed "toxæmic" There was a great pathological reason for this —viz , that the streptococcal group, however few or harmless they might be, or appeared to be, had always an intense capacity for local invasion, for causing local lesions, and for persisting in such lesions when formed They were always capable of taking advantage of any abnormal conditions, whether of the food or of the mucosa, and of becoming thereby not only saprophytic but actively pathogenic, both by increase in their number and by actual invasion of the mucosa The best example of this was afforded in the case of the summer diarrhœa of children Hence it was important to keep a close watch on the conditions that favoured the presence of streptococci or led to any accession of their numbers and virulence, and such conditions were pre eminently furnished by the septic wounds of the mouth—the conditions termed by him "oral sepsis" (1900) They furnished a continuous supply of streptococci to the alimentary tract, lower down, much of it doubtless exterminated by the bactericidal action of the gastric juice, when the digestion was in progress But much of it equally with-

[illegible]

it found everything ideal, short of this periodic removal by the peristaltic action of the bowel, for its propagation and persistence He had endeavoured to fasten attention on the rôle played by streptococci in intestinal disturbances—looseness, diarrhœa, &c —and lesions—e g , congestions, inflammations, ulcerations, &c —by giving to these disturbances and conditions the titles of "septic gastritis" of "septic enteritis" (meaning thereby streptococcal enteritis), "septic colitis," "septic proctitis" "septic appendicitis,' "septic cholecystitis," &c He thought the time had come

substituted for purely

catarrh," "gastric

colitis," "ulcerative

colitis," and still more for such vague names as "toxæmia' Oral sepsis, he continued, could, and frequently did, make the whole alimentary tract run red with disturbances to a degree which had more and more impressed him with its importance, and which had led him to recognise streptococcal sepsis and its results—viz , "oral sepsis," "septic gastritis," "septic enteritis" and "septic colitis," &c —as one of the commonest and most important causes of disturbance throughout the whole alimentary tract The reasons why the mouth was so important in relation to septic infections generally were as follows The structure and function of the gums and teeth exposed them in a special degree to violence and to injury and to consequent contraction of septic wounds of the gums and periodontal membrane (periosteum of the bone socket) When infection took place it was from its situation particularly difficult to eradicate after it had got into the socket It was then connected with bone tissue, and bone sepsis was far more virulent and toxic in its effects than sepsis of soft tissues Lastly, these wounds were in direct relation to the systemic blood without any intervening detoxicating organ like the liver to arrest or modify the toxins which they produced or the extension of the infection into the blood Oral sepsis was therefore a double handed weapon of offence in relation to the blood It could act on the blood directly, and constantly did so But the continuous stream of streptococci which it propagated passed also over the tonsils and pharynx into the gastro intestinal canal, where it modified the existing normal bacterial activities and produced in varying forms and degrees all the effects of congestion, inflammation ulceration, which it produced in and around the teeth These included acute, subacute, and chronic septic tonsillitis and pharyngitis, all degrees of adenitis, acute, subacute, and chronic gastritis, with formation of gastric erosions and ulcers, acute, subacute, and chronic congestions of the small intestine, appendix, cæcum and large intestine, and of the rectum, with and without ulceration, with or without formation of bands All these conditions were obvious and recognisable, and could be seen in the specimens he showed

SIR BERTRAND DAWSON said that the term "alimentary toxæmia" conveyed a definite clinical picture That such a condition might be produced by colon block and stasis was clear, and that when produced it was curable by putting the colon out of action by short circuiting was demonstrable His criticism would be that Mr Lane gave too great a prominence to motor defects He (Sir Bertrand Dawson) thought that the question needed a broader basis The gastro intestinal tract from mouth to anus must be viewed as a whole and from two standpoints—the motor and the infective Colonic block was not necessary to alimentary toxæmia, for it might equally well be caused by chronic infection, say of the gums, stomach, or appendix, and might be associated with diarrhœa and an empty colon That the colon had become hopelessly diseased and could not be made a working structure was the chief indication for ileo sigmoidostomy The sequence might be in one case, infection—stasis, in another stasis—infection If an infection it might begin in the gums, tonsil, or stomach, and finally manifest itself in the appendix or colon, or the ord

reversed, and starting

in either

ndarily cause chronic

infective

an ulcer As regards

treatment, he urged that all cases should be investigated from both the infective and motor standpoint It would be a tragic result of the discussion if it were followed by a "fashion" for ileo sigmoidostomy

Dr E MELLANBY said The aspect of the subject of alimentary toxæmia that I propose to deal with is the chemical one, for recently certain chemical substances have come under consideration which seem to throw some light on the subject, and are worthy of further investigation Before proceeding with the consideration of these substances I think it is permissible, even if only because of the treatment they have previously received in this discussion, to suggest that we throw overboard one group of chemical substances which until recently has received the exclusive attention of chemical researches on alimentary pathology I refer to the tryptophane derivatives and especially to indoxyl sulphate, the substances responsible for the indican test I make this suggestion for two reasons 1 That this substance, although it has been the cause of tremendous labours, including that of Herter and his co workers and the Metchnikoff school among many others, has led to no results No doubt the fact that its formation depends on several factors, of which intestinal putrefaction is only one, is the principal reason of the divergence of opinion on the subject For myself, I may say that in order to obtain a urine which gives the best indican test for medical students, it has been my custom to get that of a case of cancer of the liver rather than of a case of marked constipation 2 The indol derivatives are all relatively innocuous compared with other substances which can be obtained in the alimentary canal From a positive point of view the group of substances which I think can be readily assigned a position of importance from the point of view of alimentary toxæmias are the amines produced by splitting off CO_2 from the proteolytic amino acids by intestinal bacteria The most important of these amines have been referred to by the opener of the discussion, and are parahydroxyphenylethylamine—the amine of tyrosine isoamylamine, the amine of leucine and β imidazolethylamine, the amine of histidine Research workers have recently been attracted to these substances in consequence of the discoveries of Barger and Dale, who first isolated them from ergot and worked out their pharmacological action Their actions I need not dwell upon, as they have already been dealt with by Professor Dixon, but I may remind you that they are all very potent stimulants of plain muscle, and whereas p hydroxy and isoamyl raise the general blood pressure, β i has a marked depressant action That parahydroxyphenylethylamine and isoamylamine may be responsible for chronic symptoms of intestinal toxæmias such as arterio sclerosis seems to have been proved by the work of Harvey, who produced marked arterio sclerosis and a renal condition resembling the large white kidney by giving small quantities of these substances by mouth to animals over prolonged periods. I must confess that these results are surprising, especially when one remembers the ease with which parahydroxyphenylethylamine is rendered innocuous by having its amine replaced by a hydroxyl group and then oxidised to parahydroxyphenylacetic acid by an isolated liver prepared with Ringer's solution, as has been shown by Ewins and Laidlaw. From the point of view of acute intestinal disturbances, [illegible] must be considered. This substance [illegible] from the mucous membrane of the alimentary canal by Barger and Dale in their endeavour to identify it with the hypothetical substance of Popielski called "vaso dilatin." The mucous membrane of the intestine offered the best material for such research, for it has long been known that a watery extract of the intestine produced a very large fall of blood pressure and other toxæmic symptoms when injected into animals. In a paper on cyclic vomiting in children I stated that Twort and myself[2] had isolated a bacillus from the alimentary tract capable of splitting off a molecule of carbon dioxide from histidine and converting it into β-imidazolethylamine. Dale and Laidlaw had shown that injection of small quantities of β-i. caused, among other symptoms, marked diarrhœa and vomiting, and I suggested that the absorption of this substance into the blood stream from the intestine might be responsible for the exacerbations of symptoms in cyclic vomiting. Since this time Berthelot,[3] a Frenchman working in Metchnikoff's laboratory, has also isolated a bacillus from the intestine capable of carrying out the same action. This bacillus he has called the Bacillus aminophilus intestinalis, because of its power of attacking amino-acids. We make no such general claim for our bacillus, although there is evidence that it will attack some substances such as tyrosine and alanine. One other point where we differ from Bertrand and Berthelot most emphatically I wish to deal with. They say they can only isolate the bacillus from the intestinal contents of cases showing intestinal disorder and not from normal healthy animals. This is absolutely contrary to our experience, for we have never failed to obtain most potent histidine-destroying bacilli from any alimentary canal of normal animals that we have examined. One surmises, therefore, that Bertrand and Berthelot ascribe the symptoms of intestinal disturbances to this bacillus whenever it is present. Twort and I, on the other hand, think it is present in all alimentary canals, and that its products of activity only produce symptoms under special circumstances. The fact that Barger and Dale isolated β-imidazolethylamine from the intestinal mucous membrane of normal oxen supports the view that the bacillus is a normal inhabitant of the intestine. Its distribution is affected by the diet to some extent, for a cat that has lived on an exclusive meat diet has the bacillus higher up towards the duodenum than a cat on a milk diet. Since β-imidazolethylamine is present in the normal alimentary mucous membrane, the question arises as to why it lies in an apparently innocuous state without the production of symptoms, and also what would happen if there was an increased production of this substance in the intestine. The answer to the latter question seems clear. If minute quantities of β-i.—say 10 mgr.—be injected either intravenously or subcutaneously into a cat, then very marked symptoms of diarrhœa, vomiting, and general collapse appear immediately. If large quantities—i e., up to 500 mgr.—of β-i. phosphate be given so as to obtain access to the small intestine—i.e , in keratin capsules—then the only symptom which follows is that of diarrhœa with watery, acid stools. But there is no vomiting and general collapse—in other words, the β-i. has acted locally on the alimentary canal producing greatly increased peristalsis, but it has not been absorbed into the blood stream to produce the more important toxæmic symptoms. Without suggesting that β-i. is responsible for all the symptoms of such an acute condition as summer diarrhœa and vomiting of children, although I think it plays an important part in such conditions, and may be regarded as typical of a larger group, it seems to me that the facts just related as to β-i throw an important light on this condition. For it is clear that if β-i. is normally present in the alimentary canal, and if even when large quantities are present no general symptoms of poisoning are produced, then clearly it can only mean that when acute intestinal symptoms are produced they are due to the breaking down of the defensive mechanism of the intestinal mucous membrane which prevents the entry of β-i. into the blood stream. Such a view as this would imply that there are all the potential factors, including intestinal flora and toxic chemical substances, present in the alimentary tract of all normal animals, and that the difference between the summer diarrhœa child and the normal child is due to the breakdown of the absorptive mechanism of the intestine, and to that alone. Further evidence to this effect—viz., that the factor of importance to be considered is the absorptive mechanism and not an excessive production of toxins in the intestine—is the fact we showed that β-i. is never produced from histidine in the presence of carbohydrates and acids. Also, the acid fermentation of carbohydrates in acute intestinal disturbances is notorious, and it is unlikely that there is any production of β-i. at such times. The acid fermentation products are themselves relatively innocuous. This view would further point to a different line of inquiry for the elucidation of alimentary toxæmic conditions than that usually undertaken. For it suggests that the key to the situation is not held by a consideration of the bacteria of the intestine or of the chemical end-products of bacterial action, but rather by knowledge as to the normal method of intestinal absorption, and more particularly of the mechanism which prevents the passage of toxic substances across the mucous membrane into the bloodstream. The important question is, What is the cause in acute intestinal disturbances which brings about the breakdown of the defensive mechanism and allows the entry into the bloodstream of toxic substances? All research on this subject is handicapped by the fact that from a physiological point of view the process of intestinal absorption is almost a virgin field. The general trend of modern physiological research work on the alimentary canal seems to me to indicate another method whereby pathological symptoms may be traced to the intestine. In the first place we had Bayliss and Starling's striking discovery of secretin—a substance liberated from the duodenum by HCl of the gastric juice, and so causing pancreatic activity. The detection of gastin followed this—a substance in the pyloric end of stomach mucous membrane which was liberated into the bloodstream by various substances, including meat extract, and caused a further secretion of pepsin and HCl by the fundus mucous membrane. Again, quite recently, the results recorded by Low of work done in Hans Meyer's laboratory indicate that water taken by mouth acts as a diuretic, not by its direct action on the kidney, but indirectly by liberating some substance from the alimentary tract which stimulates the kidney to secrete water. He showed that a watery extract of alimentary mucous membrane injected subcutaneously caused marked diuresis in dogs, and if the extract was boiled it lost its diuretic effect. Such results as these, which prove the presence of chemical stimulants in the alimentary wall, make one wonder whether a generalisation is possible, so that each organ in the body is stimulated to activity by some specific chemical substance present in the intestinal mucous membrane, each specific stimulating substance being liberated by a particular foodstuff. If such a premise is correct it is clear that all sorts of symptoms might arise when an excess or a deficiency of the specific chemical stimulants is liberated into the blood stream in consequence of abnormal intestinal putrefaction or other disturbance. Work based on such a hypothesis might be useful in elucidating the causal relationship between some of the more obscure pathological conditions—as, for instance, diabetes—and the alimentary canal.

Dr. ETTIE SAYER said that her contribution to the discussion was evoked by Dr. Hale White's remark that "alimentary toxæmia has never been produced experimentally." It seemed important not to omit reference to any therapeutic procedure which involved the risk of producing the condition accidentally. One of such procedures was the attempt to reduce a raised blood pressure by means of high-frequency currents in cases of chronic auto-intoxication during periods of constipation. An excessive absorption of entero-toxins might be set up which would not only send the pressure higher, but might also produce an acute exacerbation of toxæmia. Dr. Doumer, of Lille, first pointed out that the absorbent cells of the alimentary tract naturally shared in the general increased chemical activity, and that if the bowel was loaded with retained matter which had undergone bacterial, and possibly putrefactive, changes there would be a correspondingly increased absorption of entero toxins Dr Sayer said that she had never seen so severe a case of simple constipation and toxæmia that it necessitated the removal of the colon, but had come across a considerable number which after resisting all drug treatment had yielded to electricity The forms most frequently indicated were either static or galvanic Static wave currents, or in very severe cases static induced currents, were indicated in atonic or debilitated cases where there was want of muscular power, characterised either by ptosis or by dilatation of any of the organs, and especially where local symptoms preponderated over those of systemic toxæmia Galvanic currents acted more particularly by ionisation, and were employed when it was desired to affect the mucous membrane and secretory cells rather than the muscular coat of the intestine When toxæmia preponderated over local symptoms she had found a combination of high frequency, radiant light baths and massage the best treatment For bad local patches of fibromyositis ionisation with lithium iodide gave most relief In cases of auto intoxication where the blood pressure was raised, high frequency treatment had its most important value She would like to concur with those who considered that a healthy colon was much better than no colon Before being subjected to its removal patients ought to have a guarantee that every resource of conservative medicine had been exhausted on their behalf

[2] THE LANCET, July 1st, 1911.

[3] Comptes Rendus de l'Académie des Sciences, July 24th, 1911.

Dr J SIM WALLACE said Alimentary toxæmia is due to certain abnormal conditions giving rise to undue lodgment and proliferation of micro organisms and defective elimination or control of the toxins generated We may further say in general that these conditions are induced or predisposed *to by lack of function in or near the situation where the* toxins are produced Upon recognition of the natural or physiological methods of control of the bacteria and the toxins produced can we best base a scientific and practical treatment The chief function of the saliva *is to keep the mouth in a hygienic state, to remove* food which by stagnating would undergo fermentation or putrefaction, and to control the products of fermentation sufficiently thoroughly to prevent injury to the teeth or mucous membrane of the mouth The mucous coating *over the teeth prevents acid foods from doing them harm,* and if a meal be finished with due regard to the hygiene of the mouth—e g, with fresh fruit—the mucous plaques are [illegible] G Gies) disorganised Thus, [illegible] with adherent bacteria and food [illegible] *ack of function predisposes to* alimentary toxæmia The primary function of the teeth is the *mastication of food* but the mastication of food of a detergent nature has a second function—namely, the prevention of the undue stagnation of bacteria and *food débris about the teeth The earliest effect of such* stagnation is a slight inflammation of the gum margins surrounding the necks of the teeth—that is to say, where from lack of function the greatest amount of stagnating bacteria and food débris is located When the stagnating bacteria *and débris at the necks of the teeth give rise to toxæmic* symptoms a rarefying osteitis may be set up, especially when, through lack of function, the ligamentous tissue and the alveolar processes are weak The rational treatment, then, of oral mal hygiene is the restoration of the normal *function of mastication, and the stimulation of the self* cleansing processes of the mouth In addition to food requiring efficient mastication, it is desirable to insist, as far as may be possible, on [illegible] -taining a certain amount of [illegible] leansing function of the sali [illegible] *Acids* call forth a copious [illegible] There need be no fear of the acid in fresh fruit or vegetables injuring the enamel of the teeth, this is amply provided against by the mucous coating on the teeth and a copious *flow of alkaline saliva Furthermore, the after flow of* saliva under such a *régime* clears the mouth not only of stagnating food particles and bacteria, but also washes away the disorganised mucus Remarkably excellent results are obtained by the ordinary surgical procedures, provided always that these artificial procedures are more or less consistently supplemented by a dietetic *régime* which stimulates the functional activity and self cleansing processes of the mouth When we turn to a consideration of alimentary toxæmia beyond the mouth, we note a general similarity in causation—i e, insufficient motor activity of the stomach and intestines and insufficient or perverted secretion of the bile It is of the greatest importance to take into consideration the fact that "although itself without bactericidal property the bile *nevertheless checks intestinal putrefaction—(a)* by exerting a selective influence in favour of certain organisms, such as the colon bacillus, to the disadvantage of the anaerobic promoters of putrefaction, (*b*) by inhibiting the secretion of the bacillary ferments, and (*c*) by stultifying the action of these bacterial ferments on putrescible material" Moreover, the bile "countervails the effects of the toxic products to which the intestinal bacteria give rise" (H Roger) I am convinced that if a tenth part of the attention had been paid to the value of food from the point of view of alimentary hygiene that has been paid to its nutritional value the treatment of alimentary toxæmia would have been far more rational and satisfactory than it at present is

Dr W BEZLY THORNE drew attention to the fact that 17 years ago he had delivered an address on self poisoning and heart disease which had been published in THE LANCET under that title[4] He was now more than ever convinced of the intimate connexion between the two conditions Without minimising the importance of pyogenous and other toxins, he contended that the main cause of toxæmia as affecting the circulatory organs was alimentary in origin He expanded his views as follows Normal fæcal matter was not toxic, and might be retained for two or more days with only unimportant discomfort Fluid stools, if of frequent or habitual occurrence, were always toxic Habitually pale stools were toxic, as they represented interference with the flow of the biliary and pancreatic juices, a condition *prohibitive of the normal biochemistry of digestion* and necessarily involving morbific bacterial activity The mucosa of the pelvic colon and rectum not being able to discriminate between a normal saline injection and fluid fæces, a man who frequently had fluid toxic stools, whether *as the result of saline aperients or of a morbid condition,* underwent rectal feeding on his excremental poisons Such toxæmia conduced in a high degree to degenerative change in the myocardium and in the arterial tissues, especially the tunica media Dr Thorne proceeded to give instances in *which careful dieting and intestinal correction had reduced* maximal sphygmometric readings in the higher grades by 40, 50, and more mm Hg

Dr H G ADAMSON said that the supposed relationship between skin eruptions and alimentary toxæmia had attracted *much attention, but it was a subject about which we knew* really very little Eruptions of urticarial and erythematous type were of common occurrence after ingestion of certain food poisons These were now regarded as phenomena of anaphylaxis to foreign proteids But they were, strictly *speaking, not the result of alimentary toxæmia in the sense* in which it was being used in this discussion, and he knew of no eruption which could be definitely traced to the bacterial flora of the alimentary canal, or to any *known chemical* body produced there The theory that various skin diseases *supposed not to be of microbic origin,* such as eczema, psoriasis, lichen planus, pemphigus, scleroderma, lupus erythematosus, and alopecia areata, were the results of toxins produced in the alimentary canal had some attraction, but we had no facts to support it And the results of attempts *to prove absorption of chemical products from the intestine* by estimating the amounts of ethereal sulphates and aromatic bodies in the urine had been inconclusive It seemed probable that if such bodies existed they were immeasurable by ordinary chemical methods and that we had to look to *bio chemistry for their discovery*

Dr R MURRAY LESLIE said that putrefactive changes in the intestines of healthy persons under normal conditions produced no evil results whatever, and probably fulfilled a most useful rôle in the animal economy In the great majority of *instances the protective mechanism of the* healthy organism was more than sufficient to counteract the deleterious effect of any toxins that might be produced by the various bacterial flora that normally inhabited the gastro-intestinal canal. In the course of evolution the human host had adapted itself to the presence of those bacteria which had selected the intestinal canal of man as their normal habitat. Should, however, the vital protective forces be at a low ebb from any cause, or should the intestinal flora as the result of stasis or other cause be abnormally numerous or consist of abnormal types, or should they invade portions of the intestinal tract remote from their usual habitat, then symptoms of alimentary toxæmia would sooner or later ensue. In the discussion sufficient stress had not been laid on the first of these two factors—viz., the power of resistance on the part of the individual. The different effects of constipation on different individuals illustrated the importance of this point. Habit tolerance alone did not altogether account for those differences, and there were undoubtedly individual idiosyncrasies in respect of liability or resistance to alimentary toxæmia. Evidence was accumulating that the specific action of the thyroid, genital, and other ductless glands played an important part in regard to the vital resistance to the action of alimentary and other toxins. Dr. Leslie found considerable benefit accruing from the giving of various extracts containing the products of internal glandular secretions. It was, however, with the second factor—namely, the increased quantity or virulence of the alimentary toxins—that they had been principally concerned in the present discussion, and it was of paramount importance to decide which were the conditions in the alimentary tract that predisposed to increased production of such toxins. The bacteriological evidence brought forward pointed unmistakably to intestinal stasis as being pre-eminently the condition favouring such production. There was not only increased bacterial multiplication, but abnormal intestinal flora, while the prolonged retention of the bowel contents offered special opportunities for undue fermentative activities of the bacteria and for the absorption of their toxic products. The effect of the stasis also tended to cause upward spread of the coliform and other bacteria into the small intestine, the mucous membrane of which was much more absorptive than that of the colon. The most characteristic of Dr. Leslie's cases of alimentary toxæmia had all been associated with visceroptosis and intestinal stasis. It was evident from the observations of several of the speakers that the actual quantities of indican and skatol—comparatively inert substances—that may be found in the urine must not be accepted in any sense as a criterion of the degree of alimentary toxæmia present in any individual case. The degree of toxæmia should for all practical purposes still be judged by the intensity of the clinical manifestations, while bacteriological and chemical investigations were principally of service in indicating the nature and source of the toxæmia. There was much evidence in favour of the view that many so-called blood affections, such as pernicious anæmia and Henoch's purpura, were in reality manifestations of alimentary toxæmia. He (the speaker) was a strong believer in the existence and importance of the various peritoneal adhesions and kinks described by Mr. Lane and others. The interesting evidence produced by Professor Keith in regard to the formation of peritoneal adhesions in the human embryo as early as the third or fourth month of intra-uterine life did not in any sense contraindicate the formation of similar structures in post-natal and adult life. The antenatal adhesions, many of which were only found in the case of man and the anthropoid apes, were doubtless developed to prepare the animal for the upright posture, while the post-natal adhesions were also connected with the assumption of the erect attitude, but were developed so as to counteract gradually the increasing weight of the abdominal viscera, particularly the cæcum and colon, which tended to get overloaded with solid and semi-solid contents. He had frequently witnessed X ray and operation demonstrations of these adhesions in the case of his own patients, and had almost invariably found the adhesive bands in the direction of the lines of resistance to vertical downward displacement. Patients with symptoms of chronic alimentary toxæmia, associated with stasis, if left untreated, were extremely apt to relapse into a condition of physical and mental asthenia and chronic invalidism and were further peculiarly liable to intercurrent acute and chronic disease. Treatment of some kind must be initiated to redress the balance of opposing forces—the vital resistance on the one hand and the degree of toxæmia on the other. The vital forces might be stimulated by hygienic, dietetic, and other remedies, by vaccine and enzyme therapy, and by the giving of various glandular extracts containing the products of internal secretion. The production of bacterial toxins must be diminished and their elimination facilitated. In early cases simple remedial measures, such as diet modifications (particularly reduction in animal proteids and the substitution of vegetable and purin-free diet for a certain period); aperient remedies and lubricants, particularly liquid paraffin; abdominal massage; supporting belts and physical exercises, were usually quite efficacious. It would be observed that most of these methods favoured elimination of toxins by relieving intestinal stasis, and although mere association of stasis with toxæmia did not, as Dr. Hale White stated, prove causation, still it was surely more than a coincidence that the toxæmic symptoms often entirely disappeared when the remedial methods adopted had removed the stasis. Petroleum should often be given in large doses—e.g., ½ to 1 oz. taken two or three times daily. In the speaker's experience intestinal stasis was much commoner in private than in hospital practice, and he attributed this fact to injudicious diet and habits on the part of the better classes. The substitution of a two-meal diet for the three-meal diet of to-day would probably be a great advantage. There was, however, a minority of aggravated cases with progressive emaciation and debility, and other symptoms threatening the life of the patient, where dietetic, lubricant, hygienic, and other simple measures, however carefully carried out, would fail, and his experience of a considerable number of such instances had led him to advocate strongly having recourse in these circumstances to surgical interference, with the object of removing the poison manufactory, which was usually in the colon and terminal portion of the small intestine. By far the most satisfactory surgical measure was that of short-circuiting the ileum into the pelvic colon, thus throwing the greater part of the large intestine out of action, and thereby enormously accelerating the passage of the intestinal contents. In such cases it was not only unreasonable, but also inimical to the patient's best interests to refuse to resort to operative interference. In Dr. Leslie's experience it had been those cases of visceroptosis, where the cæcum and other portions of the large intestine were bound down by adhesions below the level of the brim of the true pelvis, that simple non-operative measures often failed to give permanent relief. If there was a controlling mechanism at the ileo-cæcal opening, as suggested by Dr. Elliott and others, this would be specially apt to be interfered with in such instances, while this condition would also predispose to the formation of kinks. In most of his cases in which simple measures had entirely failed to give relief, and recourse had been had to a short-circuiting operation, accompanied in one case by colon resection, the resulting benefits had been little short of marvellous.

---

[4] THE LANCET, March 21st, 1896 p 7[illegible]5

Mr. J. LEWIN PAYNE said that the chronic nature of the complaints associated with alimentary toxæmia was largely due to the fact that a vicious circle was established, and when once oral sepsis had led to gastro-intestinal troubles the oral sepsis itself might be kept active by the secondary complaint. The amount of sepsis arising directly from dental caries was probably small, but indirectly it led to many infective processes. Pyorrhœa alveolaris was the commonest source of infection in the mouth. Dental caries and pyorrhœa alveolaris were seldom both well marked at the same time, which might be explained on the ground that caries was caused by fermentation and the production of acids, whereas pyorrhœa was a putrefactive process. He doubted whether direct absorption of organisms and toxins occurred in the mouth, through the gum, periodontal membrane, or alveolus in cases of pyorrhœa alveolaris. The chief source of infection appeared to rise from swallowing unmasticated and contaminated food. The restoration to normal activity of the mouth and teeth was an important factor in the treatment as well as in the prevention of alimentary toxæmia. Probably the chief influence in reducing the functional activity and masticatory force was the diet. He believed that pyorrhœa alveolaris was a curable disease, and the proportion of cases which could be cured without extraction was increasing. He felt strongly that by recommending wholesale sacrifice of teeth they were shirking the problem which faced them, and was convinced that the dentist of the future would not rest satisfied with that attitude. He spoke in favour of vaccines.

Dr R ACKERLEY spoke of the importance in this connexion of certain habits of civilised life and ways of dealing with food leading to imperfect insalivation No serious attempt was made to teach young children the method of insalivation. Only by active sucking was any appreciable quantity of saliva obtained He suggested that saliva had anti bacterial action, and also improved digestion and absorption of food The chief cause of abnormal conditions of the mouth was absent or imperfect insalivation

Mr S F ST J STEADMAN [illegible]
who had studied the etiolog
possibly support Mr Arbuth
secondary to intestinal stasis Pyorrhœa alveolaris was brought about by the lodgment and subsequent decomposition of carbohydrate and other soft sticky food clinging around and between the teeth If Mr Lane was correct in supposing that it was secondary to intestinal stasis, due to man's upright posture, how did he explain its occurrence in the domestic animals? It was common in all animals subjected to the will of man—i e , when their natural diet of raw uncooked food was replaced by sticky carbohydrate food He agreed with Mr Goadby that the toxins absorbed by the blood stream in close contact with the areas of rarefying osteitis in the jaws was even more important than the mere swallowing of pus He could not, however, agree with his vaccine treatment of pyorrhœa alveolaris He had watched Mr Goadby's work for some time, and was bound to confess that he was not able to corroborate the results he claimed He had not been able to detect improvement either in the local condition or in the constitutional symptoms in those cases where no local treatment had been carried out Where such treatment had been carried out there was sometimes an improvement, but he thought that was due to the local treatment and not to the vaccine He pointed out that in the majority of cases, even when great care was taken to prevent outside contamination, a swab taken from the pockets nearly always showed a mixed infection It was extremely difficult to determine which organism was the cause of the trouble in each individual case The only way at present was to take the patient's opsonic index to each organism isolated, and the result obtained was at present unreliable He thought that, in view of the fact that hundreds of teeth were being extracted for pyorrhœa alveolaris each week without any ill effect from the operation and without a previous course of vaccine, Mr Goadby s statement that a course of vaccine treatment before operating was essential for fear of dangerous constitutional symptoms could not be accepted He had himself performed this operation of extensive extraction a great number of times, and had not seen any ill effect if care was taken to render the area of operation as clean as possible before operating He agreed with Mr Goadby that extraction of the teeth for pyorrhœa was a confession of failure, but the same could be said of the surgeon who removed a leg for sarcoma An honest confession of failure was often the best course in the interest of the patient It was no advantage to a man to save either his teeth or his leg and lose his life He thought that though an educated person who was able to give a considerable amount of time and trouble to the cleansing of the mouth could sometimes arrest the disease it was incurable in the poorer classes once it was established He thought that considering the risks such patients ran of becoming chronic invalids, and consequently being constantly among the unemployed, and realising the hardship this caused among their dependents, it was a grave offence against the patients and the community to allow them to retain their teeth without clearly placing these risks before them

SECTION OF MEDICINE

Gout and Chronic Rheumatism —Ambulatory Treatment by Means of Tuberculin

A MEETING of this section was held on April 22nd, Dr FREDERICK TAYLOR, the President, being in the chair

Dr H LYON SMITH read a paper on Gout and Chronic Rheumatism, their Etiology from the Bacteriological Standpoint, and some Notes on Treatment It was based upon observations made over a period of three years on nearly 200 cases, which had been differentiated clinically and referred to as gout or chronic rheumatism respectively, yet presented many points in common Both types were examined from the bacteriologist's point of view as if they were infections of a chronic nature, and there was a close resemblance in the findings The conditions common to both included arthritis, single or multiple, periarthritis, aponeurositis, neuritis or perineuritis The associated chronic lesions which served as foci of infection—e g , pyorrhœa, chronic pharyngitis, post-nasal catarrh, bronchitis, gastro intestinal catarrhs, urethritis, cystitis, pyelitis, vaginitis, endometritis, salpingitis, and some forms of dermatitis—were briefly referred to The importance of early recognition of marginal gingivitis as a precursor of pyorrhœa alveolaris, with its attendant arthritic troubles, was insisted upon The commoner pathogenic microbes concerned in chronic inflammatory conditions and associated with gout and chronic rheumatism, such as the streptococci, staphylococci, the bacillus coli group, pneumococci, bacillus influenzæ, the diphtheroid group, gonococci, micrococcus catarrhalis, B tuberculosis and micrococcus melitensis, had been found in certain cases to play leading *rôles, but the majority of cases were due to mixed infections* This augmented the difficulty in treatment as the immunising process necessarily became much more complicated Where it had not been possible to use exact diagnostic methods, such as the opsonic index, &c , frequent bacteriological examinations of pathological exudates had been made and the clinical responses to tentative inoculations had usually been quite significant He referred to an unusual type of case, in which the diphtheria bacillus appeared to be the source of trouble and antitoxin was used with striking results, and to some illustrative cases in which a marked alleviation of symptoms was obtained by inoculation methods falling far short of complete immunisation It was impossible to summarise or dogmatise on such a subject Its protean aspects suggested a protean etiology It seemed to be agreed that alimentary toxæmia was the probable source of the various symptoms designated gout or chronic rheumatism It could be demonstrated that the ferments produced by certain bacteria acting upon various foodstuffs, besides causing the bewildering cleavage of proteins, hydrocarbons, and carbohydrates, could give rise to the formation of various organic acids—e g , lactic, acetic, butyric, hippuric, and oxalic It hardly seemed logical to cut down any one section of the diet table in the hope that by starving the host we might kill the parasite A more rational procedure was to aim at raising the specific immunity of the host to whichever pathogenic bacteria appeared to beset him most actively, taking for our models methods which had successfully produced immunities in the research laboratories

Dr T D LISTER read a paper on the Treatment of Ambulant Cases of Pulmonary Phthisis by Tuberculin (T R and B E) in the out patient room He said that several disadvantages attended on the attempt to carry out tuberculin treatment in a small out-patient department in a special hospital This arose partly from the difficulties of the patient and partly from those due to intermittent observation After a few years' experience of administration of tuberculin in the wards he started giving it to out-patients The first difficulty was to decide what observations it was possible to make Apart from the temperature chart and the general condition of the patient in relation to his physical signs truly scientific observation seemed impossible without a special department and a large number of highly qualified helpers Not every out patient had the intelligence to take his temperature accurately, and the directions given must necessarily be as simple as possible His instruction was for patients to take their temperature by mouth on waking in the morning, usually about 7 o'clock, before taking food or drink, and in the afternoon one hour after tea The thermometer was supplied for a few pence from the hospital dispensary , the charts, which lasted six weeks and were replaced when completed, were distributed in the consulting room When the patient's temperature was not verified by a medical man or district nurse one could judge only by internal evidence as to the patient s accuracy If doubt arose no treatment was begun until the patient could get further instruction or assistance The charts were kept for some weeks before he felt justified in beginning the administration of tuberculin The weekly interval did not afford the most scientific method of administering tuberculin In the wards, where patients were under continual observation, doses could be spaced with a better regard to negative and positive phases in so far as these might be inferred from the temperature chart. Difficulties also arose from irregular attendance under certain conditions of employment, from temporary migration, and from varying ability to secure adequate nutrition, in the same patient. Therefore when reactions (which he endeavoured to avoid) occurred there was not the same control over the patient as in the wards of a hospital or sanatorium. Some patients, however, took a very intelligent interest in their treatment and rested as directed immediately on any rise of temperature. For these and other reasons the out-patient treatment of pulmonary phthisis by tuberculin could be carried out with any justice to the patient and one's self in only a limited number of cases, but for this limited number of cases it was useful, justifiable, and expedient. In the selection of cases for tuberculin treatment in an out-patient department there was even a greater need for care than in making the selection for the sanatorium. As immunising ability depended on the active condition of the blood and tissue cells, nutrition was an essential point. He endeavoured to ascertain that the patients could obtain adequate food, however simple. He was equally confident that the unfavourable results which he had seen in certain cases were due to failure of nutrition, and that the favourable results seen in many other cases were due to a supply of proper food. He was not convinced that with simple instruction in the hygienic treatment of phthisis some of the latter patients would not have got well without tuberculin. He also took into account the patient's general physique. The kind of physical signs found in an infective disease producing gradual destructive changes he thought of less importance than the manner in which the organism sustained the infection. A limited severe lesion, and chronic fibrosis, even with a cavity, was to be preferred to a diffuse infiltration and subacute symptoms. The modern delicacy of diagnosis in so universal a disease must result in the detection of many cases which got well. The feature of the modern literature on tuberculosis was the establishment of the theory that nine-tenths of our population recovered from infection by tubercle. The relation of general infection and of the possible immunisation of the population to the gradual reduction in the phthisis death-rate demanded further consideration. How the patient stood the disease while untreated was an important factor in estimating his ability to benefit by tuberculin treatment. One must decide as to each case on its merits; a case with old physical signs of fibrosis, including cavitation, might be quite suitable, especially if the relapsed area was of limited extent and the constitutional symptoms were favourable. With a temperature chart normal or only slightly irregular, of limited daily range, and with nutrition fairly maintained or capable of improvement, and with no prognostic adverse factors present—poor physique, extreme poverty, bad family history, rapid pulse, and severe anæmia —one might safely begin. He had been accustomed to point to a primrose tint in the soft palate, with general anæmia of the buccal mucous membrane, as indicating cases which did not usually do well. Tuberculin treatment could be carried out in a very much larger number of cases where there was entire control over the patient than in the out-patient room. Treatment was begun only after some weeks of observation, except in cases returned to the out-patient room from the wards. From the commencement of the chart the patient was questioned as to the accuracy and care with which his chart was kept; his weight was watched, his sputum examined, and ordinary medical treatment adopted. His usual commencing dose was 0·00001 to 0·00002 of a milligramme of T.R. The first dose was rather experimental, and out-patients were especially cautioned to register their temperature carefully during the first two or three days after the dose, to tell him anything special they might notice about themselves after the injection, and to rest in bed for, at any rate, the first 24 or 36 hours should their temperature go up or should they feel ill after an injection. As a rule with the small dose indicated there were no initial reactions, nor did the patient notice any subjective symptoms which might be regarded as such. At the next visit if there was no reaction of either kind the dose was increased, usually to 0·00003 mg. All being well the dose would again be increased at the next visit to 0·00004 or 0·00005, and in succeeding weeks the dose would go up to 0·00007 and then to 0·0001, and so on until in the twenty-fourth week 0·5 would be reached. Unfortunately, a great deal of unsatisfactory and even dangerous tuberculin administration was now being carried on. Series of doses were prepared by commercial firms and issued to practitioners, who administered them with an inadequate regard to their toxicity. Tuberculin was a toxin, not an antitoxin, a fact that was often ignored in practice, and a strong protest against the present indiscriminate application of tuberculin in many forms of tuberculosis was necessary. A rise of temperature following a dose contra-indicated an increase at the next visit, and if it remained disturbed on the evening before the next visit it was advisable to omit the dose, even though this course in an out-patient involved an undue prolongation of the interval. On the following week, if the temperature was normal, the previous dose might be repeated; and if on the succeeding visit the temperature had remained normal, a progressively increasing dosage might be resumed. But should the repetition of the previous dose again be followed by a reaction it might be necessary to diminish the dose at the next visit, but no dose should be given after a reaction until the temperature had been quite normal under the ordinary conditions of the patient's life for several days. As the cost of T.R. rapidly increased when the doses approached a milligramme, and as the successful increase of dose without reactions up to 0·001 or 0·01 of a milligramme implied a considerable amount of tolerance on the part of the patient, he had in many cases commenced administration of B.E. at this stage. B.E. was much more toxic than T.R., and he did not think the administration of B.E. should be begun in the out-patient room with more than one-fifth of the previous dose of T.R. Thereafter progress in the increase of dosage would follow very much the same lines as those for T.R. If doses above 0·1 mg. of T.R. were tolerated with impunity the interval between doses might sometimes be increased. Usually he preferred to see these patients weekly even when no dose was given. When doses of 0·1 mg. B.E. were attained a fortnight might often be allowed to elapse, and when doses of one or two milligrammes were reached, the patient remaining well, the interval might be further extended to four or six weeks. He was unable to say when treatment should be discontinued. He had not taken any out-patients beyond the dose of two milligrammes of B.E. Where an apparently successful result had been obtained the patient was advised to come up at intervals of one to two months, to repeat the maximum dose which had been reached in his case. The after-care of all cases of pulmonary phthisis presented identically the same problem as that of the prevention of the disease. Economic factors had the largest place. He had as yet but little faith in the permanence of any immunity resulting from treatment of an attack of revealed or open tuberculosis by any method, but tuberculin treatment at least kept the patient under observation and guidance for a long period. The tuberculin used in his out-patient department was prepared by Dr. Hunt, pathologist to the hospital. It was sent in a series of decimal dilutions corresponding to 0·0001, 0·001, 0·01, 0·1, 1 mg. bacillary substance in each 1 c.c. It was diluted with 0·8 per cent. salt solution containing 0·5 per cent. carbolic acid, and heated to 58° C. for half an hour. The injections were usually made in the patient's arm (first washed with a lysol solution) over the outer head of the triceps or about the insertion of the deltoid. After the injection the puncture was dried and occasionally covered. The syringe was of glass, and the needles and syringe were sterilised in the ordinary manner. The doses were measured by decimal divisions of a c.c. in the syringe. A printed card of instructions as to hygiene and nutrition was given to every patient. He saw no reason for ceasing to give these patients concurrently the older remedies, but in regard to cough in ordinary cases of pulmonary phthisis he did not use derivatives of opium, and he found that liquorice and menthol pellets were usually sufficient to stop the cough when troublesome. Patients were also taught not to cough except for the purpose of expectoration. The patient rapidly acquired the power of distinguishing between the possibility and impossibility of removing sputum from his chest. His attitude towards tuberculin treatment in cases of ambulant phthisis in the out-patient room was at present rather one of investigation than of conviction. He would liken the patient's resistance to an elastic thread holding up a weight, which might be compared to the disease

If such a weight were suspended by an elastic thread so that the [illegible] sustained it easily, and [illegible] thread was momentarily [illegible] rebounded, so that for a moment the weight reached a higher position than when at rest. If the elastic cord was strengthened at the height of rebound by an additional thread, and this process were repeated, we should arrive at a position where the cord would be too strong to be [illegible] the weight. Tuberculin treat- [illegible] benefit to those patients who [illegible] f resistance." The paper was illustrated by charts on the epidiascope, and by notes of cases.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

Exhibition of Clinical Cases and Pathological Specimens.—Strangulated Inguinal Hernia in Infants.—Meningitis Simulated by Threadworms.

A MEETING of this section was held on April 25th, Mr. A. H. TUBBY, the President, being in the chair.

Dr. J. L. BUNCH showed two cases of Hereditary Syphilis treated by intravenous injections of salvarsan and neo-salvarsan. 1. A child, aged 2 years, who had been shown [illegible] Shortly after birth the [illegible] of hereditary syphilis, [illegible] n an intravenous injec- [illegible] A fortnight after the [illegible] ns had disappeared and the child [illegible] from sym[illegible] about fiv[illegible] syphilis— [illegible] lomata, [illegible] and a skiagram taken of the right wrist. This showed marked disease of the lower end of the diaphysis of the radius, with cancellation and rarefaction of the bone, and periostitis spreading well up the shaft and also involving the ulna. There seemed little doubt that these appearances were due to syphilitic disease. The Wassermann reaction was strongly positive. At 2 P.M. on April 12th, 0·04 grm. neo-salvarsan was injected into the left external jugular. At 10 P.M. on the same day the temperature rose to 103° F., but fell again next day almost to normal. The pulse rose from 120 to 136 at night. The injection of neo-salvarsan was repeated on April 19th, and the symptoms had all greatly diminished, with the exception of the bone changes. The mother still suckled the child at the hospital three times a day.

Dr. J. PORTER PARKINSON showed a case of Tuberculosis of Kidney. The patient, a boy aged 8 years, with a healthy family history, was admitted into a hospital for children two years ago, shortly after an attack of scarlet fever. He was sounded for stone in the bladder, and then the right kidney was explored from behind, but nothing abnormal detected. The urine, which had contained pus, cleared up and he was discharged. [illegible] of the Queen [illegible] side of the a[illegible] He was thin but not emaciated; the right rectus was at times very rigid, but occasionally a hard tumour could be felt in the region of the right kidney, extending two fingers' breadth below the costal margin; it was sometimes tender. The urine was normal in amount, alkaline, contained a variable amount of pus, and about 0·1 per cent. albumin; no blood. Staphylococci and tubercle bacilli were found in it. X ray report: Increased density in renal region; several shadows scattered over right loin, suggesting calcareous masses in an enlarged kidney or calcareous mesenteric gland. Two very dense shadows at lower part of right ureter suggesting calculi or calcareous matter. The left kidney presented nothing abnormal and there were no bladder symptoms. The heart and lungs were normal. The temperature as a rule was normal, but with occasional rises to 102° or 103° F., apparently due to retention of pus in the pelvis. The boy's condition had improved in hospital, and the local tenderness and rigidity had disappeared, so it was easy to palpate the diseased kidney. The question of the advisability of nephrectomy was raised.

Mr. R. H. ANGLIN WHITELOCKE showed a successful case of Cerebral Decompression for Convulsions, Jacksonian in type, in a boy aged 4 years. The patient was admitted at 9.15 P.M. into the Radcliffe Infirmary, Oxford, on Feb. 2nd of this year, with the history that he had been in perfect health until that morning, when he complained of *slight earache. He did not go to school,* but in the early afternoon went for a walk. At 5.30 he fell asleep, and at 7.30 awoke feeling sick, complained of headache and soon vomited. Soon after he vomited his face began to twitch and he began to have convulsions which were confined to the right side of his body. He was at the time quite conscious but spoke indistinctly. As the spasms continued his mother put him into a warm bath and sent for medical assistance. As the fits began to increase in duration and severity the family physician sent him to hospital. The spasms began in the face and rapidly spread to the thumb, wrist, forearm, and arm, and then downwards until the lower limb had been completely involved. The child was *then hardly conscious. Between the seizures there was but* a momentary period of muscular relaxation, and fit followed upon fit with marked regularity. There was no incontinence of urine, and no biting of the tongue. As the condition was steadily becoming worse, and as the fits were entirely localised to the one side, Mr. Whitelocke determined to perform an exploratory operation with the double object either of removing, if possible, some localised focus of cortical irritation, or of diminishing intracranial pressure in the event of there being some more deeply situated cause, such as a neoplasm or collection of fluid. The situation chosen for the opening was the neighbourhood of the Rolandic area. The dura mater bulged owing *to the presence of increased intracranial pressure.* A flap of dura mater was made and drawn aside. The blood-vessels on the surface of the exposed convolutions were somewhat engorged, but there existed no definite lepto-meningitis or gross lesion, and to all intents and purposes the exposed portion of the brain was healthy. A fine exploring cannula was then passed into the cavity of the left ventricle and withdrew a few drops of clear cerebro-spinal fluid. Suspecting the presence of a deeply placed neoplasm or perhaps a tuberculous focus, the bony disc was *not* replaced, whilst the dura mater was only partially sutured. The skin flap was restored and held in position by interrupted silkworm sutures to allow of leakage, for no other means of drainage was considered advisable. The fits ceased from the moment the dura mater was incised. The wound healed perfectly, and the child made a complete and uneventful recovery. He is now in perfect health and spirits. The interesting features for consideration were: (1) the still unascertained cause of illness, no lesion having been found; (2) the one-sided limitations of the spasms, with at first no loss of consciousness, no incontinence of urine, and no biting of the tongue; (3) the complete cessa*tion of the fits so soon* as the *intracranial pressure* was relieved by operation; and (4) the complete and rapid restoration to health after such a sudden and severe nerve-storm.

Mr. WHITELOCKE also showed examples of Enlargement of the Thyroid Gland (Goitre) in a family of five children, four boys and a girl. The respective ages were 5, 7, 9, 10½, and 12 years. The family history was that the [illegible]

[illegible] ment in his throat," so that for the first four weeks of his existence his life was despaired of, and the monthly nurse almost daily informed his mother that he could not live. For some months later he was liable on the least excitement to suffer from "fits of suffocation." This went on till he "cut his eye-teeth." *Attention was first drawn* to the condition of two others by the school inspecting doctor 18 months ago. In another the neck began to enlarge when he was aged 10 years. In the eldest the goitre only became apparent during the last six months, and not before he was approaching the age of 12 years. For the last 18 months Mr. Whitelocke had had the four youngest children continuously under observation and treatment. During this time there had been very little change excepting that the neck in the congenital case had grown a little larger and one of the others had become less. The eldest boy had only lately come under treatment, for his enlargement had been very gradual and somewhat slow, and was of only recent development. As to etiology, nothing very definite could be established beyond the fact that one was evidently a congenital case, and that the two eldest did not show symptoms until after the age of 10 years. The pathological condition was, he ventured to think, one of simple parenchymatous enlargement. Treatment had consisted in an increased weekly pecuniary allowance, the administration of cod-liver oil, iodine preparations, and occasionally iron. The home surroundings had been improved as regards warming, increased light, and general hygiene. This *régime*, steadily enforced for over a year, seemed to have arrested the glandular increase in most cases. The congenital case still remained the largest. Amongst the interesting points were: (1) the existence of the disease in *all* the children of the family, the parents being wholly exempt; (2) that the history pointed clearly and definitely to the fact that one case at least was congenital; (3) that the thyroids became enlarged in all the children whether they lived on bracing and high ground or in the relaxing atmosphere of a low-lying and somewhat damp watershed; (4) the excellent general health and spirits of the children in spite of the poor pecuniary circumstances of their parents.

Dr. H. MORLEY FLETCHER showed a case of Operative Myxœdema—Cachexia Strumipriva. The patient was a girl aged 13 years. In October, 1907, at the age of 7 years, she was admitted to hospital with a small, elastic, freely movable swelling, the size of a marble, situated in midline of the neck at the level of the thyroid cartilage, and apparently attached to the thyroid gland. The swelling was first noticed two years previously, and had been gradually increasing in size. It was removed without difficulty and was found microscopically to consist of thyroid gland tissue. She was discharged, but was readmitted on Nov. 22nd in a state of cachexia strumipriva. Three weeks after the operation she became drowsy, and swelling of the face and hands with puffiness under the eyes was observed. On admission the temperature was subnormal; the urine contained no albumin. She was treated with thyroid extract, and discharged on Dec. 11th in a considerably improved condition. Treatment was continued intermittently until December, 1908, when she came to the children's department. She had taken no medicine for at least six weeks, and presented the typical appearance of myxœdema. She was very lethargic, the skin was dry and rough, the hair over the temples very thin. The urine was natural. Pulse 66 per minute; temperature 98° F. Since then she had been taking thyroid extract continuously, but in spite of this had not progressed satisfactorily. The mental condition was good. At the age of 11 years she was in Standard V., but was put back to Standard IV. Bodily growth was fairly normal. She had never menstruated. She still presented a puffy, pallid appearance, suggestive of myxœdema or chronic nephritis, though the urine had been always found to be normal. At times she became lethargic, though as a rule she was bright and active-minded. The addition of suprarenal extract to the thyroid extract had made no apparent difference.

Dr. E. A. COCKAYNE showed a case of Distal Myopathy. The patient was a boy aged 6 years. There was no history of any similar condition in the family. The mother stated that the patient had always been undersized, and had suffered from birth with incontinence of urine and fæces. At 3 years of age she noticed that he had considerable wasting of the muscles below the knee, and that his buttocks were small. She did not think the wasting had progressed much since it was first noticed. The boy seemed to fall over rather easily. The patient was very small for his age, 37¼ in. in height, but was of normal intelligence. The face, arm, and trunk muscles appeared natural. There was marked symmetrical wasting of the glutei and of the leg muscles below the knees. The thigh muscles were well developed. There was no deformity of the feet, and all movements could be carried out naturally. There was usually some cyanosis of the legs below the knees. No fibrillation had been observed. Sensation to touch, pain, heat, and cold over both arms and legs was natural, and muscular sense was preserved. The knee-jerks were brisk, but neither ankle-jerks nor plantar responses could be obtained. Dr. Cecil Lyster had kindly examined the electrical reactions on two occasions, and reported that there was no alteration either qualitative or quantitative even in the wasted muscles. He stated that a skiagram showed a narrow pelvis, and changes in the epiphyses of the long bones characteristic of rickets. But for the implication of the glutei muscles the distribution of the wasting resembled that seen in an early case of peroneal atrophy of the Charcot-Marie-Tooth type. Soca had described a case of this disease in which the arms were unaffected, and in which the glutei, though normal in appearance, showed well-marked reaction of degeneration. Against this diagnosis was the fact that there was no alteration of sensation and no change in the electrical reactions. Though it did not fall into any definite group of the myopathies he (Dr. Cockayne) had preferred to call it a distal myopathy rather than a myelopathy.

Mr. G. BELLINGHAM SMITH showed a case of Congenital Absence of Abdominal Muscles and other Defects in a baby aged 2 months. The infant was the first child of healthy parents. On examination the abdomen was flattened from before backwards, while there was a distinct bulge in either loin, which was markedly accentuated whenever the infant screamed or strained. Centrally there was a wide flattened median band stretching from the ensiform to the pubis which represented the rectus sheath. If the abdomen was palpated on either side of this central band the coils of intestine could be readily felt, apparently only covered by skin, fascia, and peritoneum. The central sheath itself could be easily picked up between finger and thumb, and suggested to the feel merely a band of fibrous tissue without any intervening muscular tissue. The whole of the abdominal wall failed to react to electrical stimulation. In addition to this apparent lack of muscular tissue in the abdominal wall the infant also presented other congenital defects. The right leg was kept slightly flexed at the hip- and knee-joints, and was said to be moved but very little. There was a moderate degree of genu valgum and talipes calcaneo-valgus present on both sides, the latter condition being more marked on the right side than on the left. Over the præcordial area there was a faint systolic murmur, which was loudest in the region of the impulse. In all other respects the infant appeared to be healthy.

Dr. J. D. ROLLESTON showed a pathological specimen of Diphtheria of the Œsophagus. It was from a boy, aged 6 years, who was admitted to hospital on the fifth day of the disease. Death occurred within one hour of admission. The specimen showed a normal condition of the upper part of the œsophagus. The lower 1¾ inches showed longitudinal areas of congestion. A small piece of membrane was visible at the upper part of his congested area, and there were larger patches of membrane present at the cardiac end. The membrane was also present in the nasopharynx, larynx, and trachea. The stomach was normal. Pure cultures of Klebs-Loeffler bacilli were obtained from the lesions in the throat and œsophagus.

Mr. WHITELOCKE read a short paper on Two Successful Cases of Operation for Strangulated Inguinal Hernia in Female Infants of the ages of 22 and 17 days. 1. In September, 1912, a female infant, 22 days old, was admitted under his care into the Radcliffe Infirmary. The mother stated that the baby was entirely breast fed, and that for the last five days nothing had passed through her bowels. The family attendant, without seeing the child, advised the mother to give it castor oil; this, however, was invariably vomited as soon as swallowed. The infant had vomited for three days, had moaned almost continuously as if in great pain, and had slept hardly at all during the whole of this time. When examined, a firm tense swelling was found in the right inguinal region of the size of a small hen's egg. Both legs were tightly drawn up, and the child was blanched and obviously very ill. A few drops of chloroform were administered, and after the necessary surgical preparations had been made herniotomy was performed. In the hernial sac were found the right ovary and Fallopian tube, together with a small loop of the small intestine. This last was severely strangulated, was purple black, but shiny. The circulation was gradually restored by the application of a warm saline wash, and the colour soon improved. The contents of the sac were returned to the abdomen, the neck of the sac ligatured, whilst the sac itself was excised and the operation rapidly completed Recovery was perfect and quick, and the babe became well grown, fat, had a firm scar, and showed no after effects from the operation 2 On March 6th of this year Mr Whitelocke was called into the country to see the female infant of a lady who had been confined only 17 days previously and who was still in childbed. The family physician informed him that the child had been screaming much since birth, that it had vomited all its food for nearly three days, that its bowels had not moved even with the use of glycerine suppositories for four days, and that it refused the breast In the right groin was a swelling, tense, tender, and tympanitic, the size of a small Tangerine orange He decided to operate at once, realising that he had to deal with a strangulated inguinal hernia in a very young and feeble subject After the necessary preparations had been hurriedly made, and with the help of chloroform, he cut down upon and opened the sac The contents consisted of a swollen and very œdematous cæcum with a long discoloured appendix vermiformis The appendix was exceptionally large [illegible] the presence of a [illegible] upon itself so as [illegible] strangulation This organ was quickly removed, and after considerable difficulty at the internal ring he succeeded in returning the swollen cæcum The internal abdominal ring admitted two fingers The sac was ligatured, and the wound closed and dressed with collodion In a very short time after the little one took the breast, passed urine, and fell asleep The bowels were moved naturally some hours later, and the wound healed without any trouble He had recently heard that the patient was thriving and was in all respects well Several points of interest to the surgeon might be gathered from the experience of these cases, and amongst them might be noted. (1) the early ages at which strangulation occurred, and with apparently no definite cause, (2) the unusual nature of the hernial contents, in the one case an ovary and tube as well as small intestine, in the other an unduly mobile cæcum with large appendix measuring 3½ inches, (3) the successful issue in each case even after the obstruction and symptoms of strangulation had lasted for over three days, (4) the absence of post operative shock after a general anæsthetic and herniotomy, and in the younger infant after appendicectomy in addition Herniotomy in such young infants must be exceptional, and a successful appendicectomy at the age of 17 days was certainly so

Mr WHITELOCKE also read a paper on a case simulating Meningitis in which the symptoms were caused by the escape of threadworms into the peritoneal cavity through a perforated appendix The patient, a girl of 5½ was admitted into the Oxford County Hospital in May, 1910 She was sent in with the diagnosis of tuberculous meningitis, seeing that a year previously an enlarged gland had been removed from the side of her neck When examined it was noticed that she seemed very ill, had a temperature of 102 4° F, and a pulse-rate of 112 There was marked converging strabismus with contraction of both pupils, and some photophobia Her mother stated that for 36 hours or more she had been sick at irregular intervals, was restless, and now and then *screamed out when apparently dozing* She was very constipated, and an enema had produced but a small result She slept badly and often refused food, any attempt at drinking brought on immediate vomiting She had urinary incontinence There was no disease of the ears or air sinuses For the first two days after admission her condition and symptoms remained about the same, but after this she began to pick at the bedclothes, to throw herself about in bed in a restless irregular manner, and to wet herself more frequently At this period Mr Whitelocke noticed for the first time that she kept her right lower limb fully flexed and drawn up to the abdomen whilst she moved the left from time to time, often extending it Palpation of the lower abdomen gave the impression of increased rigidity in the right rectus muscle and caused her to call out when even gentle pressure was brought to bear over the cæcum On percussion there was no distinct dulness anywhere The existence of these physical signs on the right side, together with the increasing sickness, quickening pulse, and general weakness, determined him to explore the region of the appendix The mother readily assented to the operation, and with complete ether narcosis he operated, utilising the McBurney or gridiron incision When the peritoneum was opened a small quantity of semi purulent fluid escaped, emitting a fæcal odour An inflamed process of omentum was found covering in the anterior surface of the cæcum and the appendix completely In peeling the inflamed omentum from the appendix he came upon a colony of about a dozen dead threadworms After the appendix had been cleared and delivered through the wound it was found to possess a pin point perforation ¾ inch from its distal extremity on its mesial aspect Through the minute perforation a living threadworm was to be seen wriggling until it finally extruded itself on to a swab held to receive it In quick succession three or four others of smaller size, and presumably of less mature age, passed in single file through the opening The base of the appendix was crushed and ligatured, and the organ excised according to custom The omentum was then drawn into the wound and carefully examined, as a result three more live worms were removed from its meshes at some distance from the inflamed and previously attached portion In swabbing the pelvic peritoneum with hot saline in search for others, four more live ones were caught and removed The wound was then closed The appendix when cut open was found to be crammed full of oxyurides of all sizes and ages The very small and immature worms greatly predominated The mucous membrane was considerably ulcerated, especially in the immediate neighbourhood of the perforation The opening was so small that a fully grown oxyuris squeezed itself through with decided difficulty After the operation the nervous symptoms and sickness very soon disappeared, the pulse and temperature fell to normal on the following day, and from this time onwards the recovery was rapid and complete The case presented many points of interest, and amongst them may be enumerated 1 *The difficulty in making a* rational diagnosis in the first instance was increased by the existence of an almost positive tuberculous history on the one hand, and by the entire absence of any other known cause on the other 2 The nervous symptoms played such an important rôle, and the pain was so generalised during the first and subsequent examinations, that there was little to direct attention to the local focus in the lower abdomen 3 The only truly localising and diagnostic symptom was the continued flexion of the right lower limb 4 The imitation of a true organic lesion or lesions by the reflex irritation caused by the active animalcules wriggling about on the exquisitely sensitive peritoneal surface. 5. The immediate cessation of the urgent symptoms as soon as the cause had been removed 6 To the surgeon especially the behaviour of the omentum in coming to the rescue in this case as it so often does in others, by limiting and preventing the extension of local mischief In this particular case it appeared not only to have checked the peregrinations of many of the worms, but it seemed to have actually killed them The colony of dead worms was to all appearances encased by the adherent omentum and held in bondage, as it were, in the immediate neighbourhood of their place of exit from the cavity of the appendix 7 The absence of infection as the result of the perforation although there was a free escape of an odoriferous semi purulent discharge on to the peritoneal and wound surfaces A drainage tube was used only during the first 24 hours after the operation The case was unique in the operator's experience, and he had neither heard of a similar case nor had he seen an account of one in surgical literature

SECTION OF BALNEOLOGY AND CLIMATOLOGY

High Blood Pressure

A MEETING of this section was held on April 17th, Dr F A MOUILLOT (Harrogate) being in the chair

Dr W EDGECOMBE (Harrogate) read a paper on the Significance, Treatment, and Prognosis of High Blood Pressure, of which the following is a summary The measurement of blood pressure by the mercurial manometer is on the whole, reliable and forms a useful clinical guide There is a condition of functional or "neurotic" high blood pressure not due to arteriosclerosis and distinguishable from hyperpiesis, in the majority of cases of functional high pressure direct treatment is unnecessary and may be harmful, functional high blood pressure does not readily lead to arterio-sclerosis; the significance of high blood pressure is less serious than usually supposed. The treatment of early cases of hyperpiesis is imperative and usually satisfactory—spa treatment gives the best results; the treatment of developed arteriosclerosis is unsatisfactory, and should be by general measures and periodic spa treatment rather than by drugs; excess of treatment may be harmful as liable to accelerate cardiac defeat; the prognosis in cases of high blood pressure is less gloomy than usually considered.

Dr. A. MANTLE (Harrogate) then read a paper on the Undesirability in Confirmed Cases of High Blood Pressure of Actively Applying Therapeutic Means to Reduce it, which appears in full in this issue of THE LANCET.

Dr. C. W. BUCKLEY (Buxton) reported a case of high blood pressure in a woman, aged 38, whose systolic pressure had persisted between 240 and 270 for the three years during which she had been under observation. Her most troublesome symptoms were neurotic, chiefly obsessions. Treatment had proved unavailing, even rest in bed for a prolonged period, but thyroid gland seemed to be of some benefit. Cardiac hypertrophy gradually developed, also albuminuria. He referred also to a case with a similar range of pressure in a woman, aged 55, with no symptoms definitely referable to this, but who had rapidly developed all the appearance of an old woman.

Dr. W. BEZLY THORNE endorsed the views impressed by both Dr. Edgecombe and Dr. Mantle, especially as to the danger of attempting to lower blood pressure by means of vaso-dilators. That proceeding, he said, hastened the failure of cardiac compensation, increasing general weakness and dyspnœa, and encouraging œdema. In the course of 15 sphygmometric observations he had never known digitalis to raise blood pressure. On the other hand, he had found the solution of adrenalin, orally administered, to lower maximal readings, apparently by bringing the muscular tissue of the arteries into action and stimulating conductivity. He strongly advised making diastolic in conjunction with maximal records of pressure

Dr. R ACKERLEY (Llandrindod Wells) said he could not regard high blood pressure as the cause of the symptoms associated with it. As regards food, he did not think red meat, or any other form of nitrogenous food, was necessarily dangerous. Few meals, moderate or small in quantity, avoidance of common salt, and free flushings with water apart from meals, were the essential dietetic rules. Starchy foods, imperfectly insalivated, were dangerous, as they fermented in the bowel.

Dr. C. O. HAWTHORNE expressed the opinion that to present sphygmometric readings in terms of blood pressure was hardly justifiable. He agreed that a mere high reading was not a claim for active treatment. He doubted if any drugs had a sustained effect on high readings, and the action of nitrites was only short-lived.

Dr. F. H. HUMPHRIS quite agreed with the prevailing sentiment of both papers which had been so ably argued, but, on the other hand, he entered a protest against the suggestion that the treatment of a high blood pressure by high frequency was disappointing. If it were so, either the choice of the case or the technique was at fault. Too often the current used (d'Arsonval) was limited in amount to 250–300 ma., whereas it should be 1000 ma. and upwards. With this current the reading should be 10 per cent. lower at the end than at the beginning of the treatment.

SECTION OF ELECTRO-THERAPEUTICS.

Use of the X Rays in the Diagnosis, the Causes, and the Terminations of Gastric Ulcer.

A MEETING of this section was held on April 18th, Dr. REGINALD MORTON, the President, being in the chair.

Dr. ALFRED C. JORDAN, in opening a discussion on the Use of the X Rays in the Diagnosis, the Causes, and the Terminations of Gastric Ulcer, said the main interest centred on the chronic ulcers. Acute ulcers gave rise to a very persistent spasmodic constriction at the site of the ulcer, but the converse was not always true; he had often seen a most persistent constriction at a particular point of the stomach—present on several days—and no organic lesion was found on operation. Chronic gastric ulcers occurred typically at two points—at the pylorus and at the middle of the lesser curvature. At the pylorus an ulcer produced a permanent spasm which was equivalent in its effect to pyloric stenosis and led to dilatation of the stomach, the appearances of which, on X ray examination, were well known. In some cases reversed peristalsis was seen, strong waves passing from the pylorus toward the cardiac end of the stomach. Sometimes a series of reversed waves would alternate with a series of waves in the normal direction—or *vice versâ*. If a complete examination of the gastro-intestinal tract were made in cases of gastric ulcer it would be found that intestinal stasis was at the bottom of every case. The manner in which this led to gastric ulcer would be clear from the instances he had to show. The constant occurrence of duodenal distension in intestinal stasis was now well known. The effect upon the stomach was great; the high pressure in the duodenum caused the stomach to work abnormally hard to get a portion of its contents out through the pylorus, which thereupon closed to prevent regurgitation. The pyloric spasm was greater still when the gastric contents were too acid. The spasm thus produced tended to persist, simulating pyloric stenosis, and making it difficult to demonstrate the duodenal distension by the X rays. The difficulty was best overcome by giving the carbonate of bismuth in a large dose about an hour after a meal, and adding a little sodium bicarbonate if necessary. In a normal case the duodenum was narrow and short, and the bismuth passed through it so quickly that no photograph could be obtained with an ordinary apparatus. In stasis cases the behaviour of the duodenum was quite different; it was too wide and too long; it showed strong peristaltic contractions, but there was repeated regurgitation of the bismuth from the fourth and third to the second part of the duodenum, little or no bismuth succeeding in passing through and entering the jejunum. In such cases the bismuth remained in the duodenum many minutes, and it was easy to obtain a photograph by inserting a sensitive plate beneath the fluorescent screen, and leaving it there while observing the behaviour of the duodenum. All his patients were examined in the same way, and the "static" duodenums could be picked out from amongst the normal with the greatest certainty. His results, both normal and abnormal, had been tested over and over again at operations, and had been found to be accurate. As the stomach dilated it was dragged down by its excessive weight, and the weight of the overloaded transverse colon was added to that of the stomach, an ulcer appearing eventually at the point of greatest strain, the pylorus. The effect of dropping of the viscera had been explained by Mr. Arbuthnot Lane; if the liver dropped, carrying the pylorus down with it, the point of greatest strain was shifted to the lesser curvature, and an ulcer then appeared there. It would be understood that the mechanical factor furnished the predisposing cause; the determining cause was microbic, and perhaps in part chemical. Bacillus coli had been found in pure culture in the depressed base of chronic ulcers of the lesser curvature. These formed a most fascinating study. The depressed base of the ulcer occupied some part of the lesser curvature. The raised crater-like margins of the ulcer were well seen, but the most striking feature was the firm, spasmodic contraction of the circular fibres of the stomach over the area of the ulcer, giving rise to a tight hour-glass constriction, a narrow isthmus joining the cardiac with the pyloric portion of the stomach, permanently except under an anæsthetic. This fact was very important to surgeons, for at operations they saw no hour-glass appearance The form of the stomach in a typical case was remarkably constant; the pyloric portion presented a nightcap-like projection upwards, the reason of which became clear if one drew a diagram of the stomach with the chronic ulcer, and represented on the drawing the effect of the abrupt shortening of the circular fibres over the ulcer and nowhere else. The pyloric portion was usually large and low, showing that gastric dilatation had existed before the appearance of the ulcer. This was as would be expected from the explanation already given, for the duodenal distension had previously led to pyloric spasm, ulceration, or actual stenosis As to the fate of these chronic ulcers, some persisted for years often unrecognised (though the X ray examination would obviate that in the future). A few cicatrised completely, leaving a varying amount of hour-glass constriction. Others became cancerous. This had often been denied, but radiography afforded positive proof. He was able to show early cases of cancer with the typical appearances of a chronic ulcer, and more advanced cases showing more modification from the typical form. Lastly, there were the most advanced cases of cancer in which the origin from a chronic ulcer could no longer be demonstrated. Thus they had another instance of the importance of intestinal stasis in the causation of cancer. The series of lantern slides illustrated the typical form of the stomach in gastric ulcer, the transition to cancer, and in all cases the accompanying evidence of marked intestinal stasis—viz., the distended duodenum, the ileal stasis (with an ileal kink in some cases), and the prolonged stasis in the large intestine. Every slide shown had been fully confirmed by operation or by post-mortem examinations. Dr. Jordan then referred to the importance of recognising the signs of intestinal stasis in the earliest stages before permanent injury had befallen organs such as the stomach. He was frequently able to recognise an ileal kink in its very beginning, when it consisted of nothing but a slight local thickening of the mesentery of the last inch or two of the ileum. Even the early stages produced an inevitable reaction on the duodenum, which became distended, and secondarily on the stomach in the manner already explained. Lastly, he would again insist on the importance of a complete examination of the gastro-intestinal tract in all cases of gastric ulcer. The gastric disorder was merely an end result; the radiologist must bring all the resources of his art to the elucidation of its primary cause, and to a large extent he would be successful.

Dr. A. E. **BARCLAY** (Manchester) followed with a paper which was strongly supported by a number of radiograms. His contention was that post-mortem and operative findings were not necessarily a true guide to the condition during life. The X ray method was the only feasible means of studying the stomach *as* it fulfilled its functions. The stomach was a sensitive organ, in which purely *spasmodic contractions* of various types were frequently seen. These spasmodic contractions were of great functional importance, and might so narrow the lumen that actual obstruction resulted. Powerful peristalsis might force an unmasticated bolus through, and cause an abrasion which later on became an ulcer. Ulcers of the stomach were almost invariably associated with spasmodic contractions, and these ulcers probably caused such contractions, though it was likely that, in the first place, the ulcer was indirectly due to the spasm. The chronic gastric ulcer was the result of the vicious circle so formed. Spasmodic contractions might be due to a variety of causes, the removal of which might cure *the patient, but this would not necessarily result* if an ulcer had formed, as a vicious circle had become established. The irritation of the ulcer perpetuated the spasmodic contraction, which made the site of the ulcer a narrow channel through which the food had to be forced. Gastric ulcer was a sequel to functional or organic lesions of other parts of the alimentary tract, and its formation depended chiefly on physical causes.

Mr. A. E. **JOHNSON** said he considered that the most hopeful line in treatment and diagnosis was for radiography to be applied to early cases of dyspepsia, and for medical treatment to be persisted in for some time, and in the eradication of all sources of sepsis before undertaking any operative measures.

Mr. C. **THURSTAN HOLLAND** said it would be interesting to know, with regard to etiology, whether the constipation preceded the stomach symptoms, or *vice versâ*. He was sure that in some cases of gastric ulcer there was no constipation. Moreover, if constipation was so often a cause of the symptoms of gastric ulcer and hour-glass contractions of the stomach, why did simple gastro-enterostomy of the upper segment frequently cure the patient? Dr. Jordan appeared to believe that cancer often occurred on the top of old chronic gastric ulcers; but in the whole series of cases of gastric ulcer at Liverpool malignant disease did not occur in any one of them.

MIDLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Exhibition of Specimens.—Dysmenorrhœa and Sterility.

A MEETING of this society was held at Birmingham on April 8th, Dr. E. **MALINS**, the President, being in the chair.

Dr. C. E. **PURSLOW** showed a large Cystic Tumour of the Kidney which he had removed by abdominal section. The patient, who was 35 years of age and single, presented a cystic swelling of the size of a seven months' gravid uterus; it was lobulated and freely movable and extended across the middle line, though lying more on the right side of the abdomen. It could be felt from the vagina and not from the loin, and, in fact, showed all the characters of an ovarian cyst, and was diagnosed as such. As soon as the abdomen was opened the tumour was seen to be renal in origin; the outer layer of the ascending mesocolon was incised and the tumour removed after tying off its attachments. The peritoneum of the mesocolon was closed with sutures and the abdominal wall closed without drainage. The patient made an uninterrupted recovery. The cyst was found to be formed in about equal proportions by the dilated pelvis and the distended cortex, little or no kidney tissue being left unaffected. Even after operation the most careful questioning failed to elicit anything in the previous history which would have given a clue to the condition.—Dr **WALTER C. SWAYNE** observed that he had had precisely a similar experience to that recorded by Dr. Purslow. In his case it was quite impossible to say before operation from which side of the abdomen the tumour had arisen. Even when the abdomen was opened the organ was only diagnosed as being kidney by reason of the loose peritoneum over it.—Dr. T. **CLARE** recorded an instance of an enormously dilated kidney becoming manifest immediately after labour. In this case the condition had in no way interfered with pregnancy or labour.—Dr. **THOMAS WILSON** remarked that he also had been misled in diagnosis by a renal tumour. Two or three years ago he had diagnosed a case as axial rotation of an ovarian *cyst complicating pregnancy, but operation proved that* it was a suppurating hydronephrosis which had become infected from the ascending colon. Again, more recently he had seen a case which had been diagnosed as an ovarian cyst, but which he thought was an omental cyst. Laparotomy disclosed a cyst in relation with the left kidney. He had removed the kidney, but since had regretted this as he thought that in this case it would have been possible to leave a portion of the organ.—Dr. F. **EDGE** was interested in Dr. Wilson's remarks and wondered how far it was possible to leave a portion of the kidney with a good prospect of retaining its functional activity.—Mr. K. M. **PARDHY** thought that in these difficult cases the diagnosis frequently depended *upon whether a general surgeon or gynæcologist saw the* patient. He had seen more than one instance where a tumour was diagnosed by a general surgeon as a movable or cystic kidney, which proved at operation to be a cyst of ovarian origin.—Dr. **PURSLOW**, in reply, said that although correct diagnosis was, of course, highly desirable, in this particular case it did not affect treatment. Removal of the tumour was the only course open to him. Two diagnostic points occurred to him which had been cited as useful by a general surgeon—viz., if pain was produced upon pushing the tumour down into the pelvis it was likely to be of renal origin; if the tumour projected markedly forwards it was probable that it was connected with the ovary.

Dr. **THOMAS WILSON** showed the Fœtus and Sac from a case of Full-term Intraligamentary Gestation. A point of considerable interest was the fact that the patient had never shown any signs of pregnancy and was unaware of the
[illegible] Menstruation had been quite
œtus had undergone "aseptic
remarked upon the extreme
in the diagnosis of a fœtus
the abdomen had been opened.
served that when the liquor
amnii had drained away at times it was extremely difficult to diagnose a pregnant uterus from a fibromyoma.—Dr. S. **LEWIS GRAHAM** asked for information as to the size of the uterus, since in a case of full-term ectopic gestation *that he had seen under the care of Dr. Copeland Savage the*

uterine sound could be passed for 9½ inches. In this case fœtal movements were quite evident.—Dr. **Wilson**, in reply, said that he did not think it would be possible for anybody to diagnose correctly the condition before operation in this case. There was no menstrual history, no evidence of false labour, and no fœtal movements. The uterus was quite small and certainly not more than 3 inches in length. He had seen two cases of full-term extra-uterine gestation besides the present one. One of these had been under the care of the late Mr. Lawson Tait. The other he saw last year at Manchester under the charge of Dr. W. E. Fothergill. The diagnosis had been correctly made in this case by the practitioner who sent the patient to hospital.

Dr. **William Smith** showed a Uterus the seat of Multiple Fibromyomata, interstitial and subperitoneal, complicating a two and a half months' gestation. He had removed the uterus from a woman, aged 30, whose menstrual periods had always been regular but excessive until January, 1913. The last period terminated on Jan. 28th, and five weeks later she sought advice on account of an abdominal tumour. The swelling rapidly increased in size, and three weeks later it was decided to explore, and if necessary remove, the uterus. This was done on April 3rd, 1913, and the patient made a good recovery. The largest fibroid was situated low down upon the anterior wall and would have obstructed delivery per vias naturales. The patient had had no pressure symptoms and was in good health. The reason why hysterectomy had been performed instead of awaiting events was the extraordinarily rapid development of the mass whilst under observation.—Dr. **Wilson** said that the treatment of such a case as this could well form the subject of discussion before the society. The general rule now adopted in this complication was as far as possible to allow the pregnancy to go to term and to interfere only if accident occurred. He had himself removed a pregnant uterus with fibroids upon two occasions. In one case the tumour had appeared clinically to be a sarcoma, and this was the indication for operation. In the other case retention of urine and severe pain had called for treatment. In such a case as Dr. Smith had shown he thought that it would have been preferable to allow the pregnancy to continue to term and then deliver by Cæsarean hysterectomy if necessary.—Dr. **Swayne** agreed with Dr. Wilson's views, and said that the opinion now largely held was not to interfere in these cases unless dangerous symptoms arose. The class of operation must be decided by the conditions present. Myomectomy had a very definite place in this connexion, and he had successfully enucleated fibroids during the early months of pregnancy without disturbing the gestation.

Dr. **Smith** also showed the Right Uterine Appendages from a case of Tubal Abortion with extensive Pelvic Hæmatocele. The specimen had been removed from a patient, aged 34, married three years, and with no history of previous illness. The last menstrual period began Oct. 20th, 1912. Upon Jan. 4th, 1913, severe uterine hæmorrhage occurred and she felt very ill. She remained in bed for a week, and on Jan. 13th her temperature reached 102° F. Vaginal examination revealed a large swelling in the region of the right appendages and Douglas's pouch. The pyrexia sudsided but anæmia became progressively worse. Until the anæmia increased a diagnosis of pyosalpinx secondary to early uterine abortion had been made. As the swelling increased in size, however, coincidently with a general improvement in the symptoms except the anæmia, ectopic gestation was diagnosed and laparotomy performed. The ostium of the right tube was found communicating with a large hæmatocele and recent blood was issuing from its lumen. The patient made a good recovery.

Dr. **Clare** read a short communication upon the Pathology and Treatment of a case of Dysmenorrhœa and Sterility.—Dr. **Swayne** thought that some cases of dysmenorrhœa and sterility might be due to malposition of the cervix and to acute anteflexion. He had had a small experience in altering the position of the cervix as suggested by Dudley, of Chicago, and had found that the operation relieved the sterility but not the dysmenorrhœa.—Dr. **Purslow** remarked that he had always considered that stenosis of the os internum was one of the causes of dysmenorrhœa, and not contraction of the os externum. In the cases quoted it was the latter that was affected.

Mr. **Pardhy** showed the following specimens: (1) Fibroid closely Simulating Pregnancy. (2) Fibromyomata of the Uterus from a patient who first recognised the tumour at the age of 20. Increase in size had been gradual until the age of 42. The neoplasm then caused inconvenience from its size, but the menstrual history had always been normal. (3) Uterine Fibromyoma associated with two very large Ovarian Cysto-adenomata.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

Spleno-Medullary Leukæmia.—Iodoform and Benzoyl Chloride in Pulmonary Tuberculosis.

A MEETING of this section was held on April 4th, Dr. J. F. O'CARROLL, the President, being in the chair.

Dr. **T. G. Moorhead** reported a case of Spleno-Medullary Leukæmia occurring in a boy aged 11, who was treated by X rays. At the beginning of the treatment the white cells numbered 325,000 per c.mm., and the red cells 1,735,000 per c.mm., and the boy's weight was 5½ st. After five weeks' treatment, with exposure of five minutes every third day, the white cells had sunk to 19,600, the red cells had increased to 3,217,000, and the weight was 6 st. 4 lb. At the same time the spleen had diminished considerably in size, and the general health was much improved. The X ray treatment was then unavoidably discontinued, and a month later a severe relapse was observed, the white cells having gone up to 192,000 per c.mm. Shortly afterwards symptoms of miliary tuberculosis supervened, and death occurred. In spite of the apparent immediate beneficial effect of the X ray course the rapid termination of the case suggested that possibly the effects of X rays were not really remedial, and that as a result of their use the resistance to tubercular infection in leukæmic cases was *diminished*. That suggestion was supported by the records of other cases. —Professor **E. J. McWeeney** said his experience closely coincided with Dr. Moorhead's—i.e., the influence of the X rays in causing a diminution of the spleen and an amelioration of the symptoms. A point that struck him was the absence of granular cells which was met with in a great many cases. Ehrlich indicated that a large number of eosinophile cells was thought to be the most marked feature in leukæmia, but the demonstration of such a feature in practice was difficult. With regard to the termination of the case by acute miliary tuberculosis he had a similar experience in one of his cases.—Mr. **M. Hayes**, from his experience in the treatment of several cases, extending over the past six or seven years, by X rays, said that he had found that there generally came a time when X ray exposure had absolutely no effect no matter how long or regularly it was continued.

Dr. **J. B. Coleman** read a paper criticising the Treatment of Pulmonary Tuberculosis by Iodoform and Benzoyl Chloride. In 1911 the iodoform-benzoyl-chloride treatment by intramuscular injections was carried out in Steevens' Hospital, Dublin, on patients suffering from pulmonary tuberculosis. Four out of seven patients so treated died in the hospital, and the treatment was subsequently discontinued. This was the method of treatment which the medical staff of the Royal National Hospital for Consumption for Ireland refused to sanction when it was suggested for trial in the hospital. Amongst the objections to the treatment of pulmonary tuberculosis by iodoform was the fact that the drug was a weak germicide, not fatal to bacteria; if dusted over sterilised nutrient media growth took place from organisms contained in the iodoform itself, and it was not monotropic for the tubercle bacillus, in the sense in which the term was used in connexion with the specific chemo-therapy of Ehrlich. On the other hand, iodoform was toxic, causing such symptoms as malaise, wasting, anorexia, vomiting, fever, tachycardia, insomnia, delirium, headache, prostration, albuminuria, loss of power in the legs, loss of control over the sphincters, and even death by coma (Treves). Iodoform was also harmful to the eye. In many instances retrobulbar neuritis followed its introduction into the system (Critchett, Terson, Priestley Smith, &c.), and after prolonged use atrophy of the optic nerve had followed. According to Terson it caused retinal hæmorrhage. In pulmonary tuberculosis the *intravenous* injection of iodoform was attended with special dangers, as it was liable to be followed by severe attacks of coughing, thereby entailing risk of hæmoptysis or of pneumothorax—a risk which could not be justified in the absence of any proved counter advantages due to the administration of the drug *Mutatis mutandis*, the rules laid down in October, 1912, by Sir Almroth Wright for investigating the effect of ethylhydrocuprein hydrochlorate in pneumonia applied to an inquiry on similar lines in reference to the use of iodoform in pulmonary tuberculosis —Dr Walter G Smith said that when called upon to judge of the success or otherwise of any method of treating disease there were two postulates—(1) an adequate knowledge of the drugs or methods used, and (2) sufficient clinical and scientific evidence of their fitness There might be a third, but doubtful, method—viz, the method of analogy Enough was known about iodoform to justify doubt whether a half grain dose introduced into the body of a man exercised any influence Ample experiments had been made as to its germicidal and bacteriological qualities, and they were ascertained to be extremely feeble A 50 per cent solution of the drug would hardly kill even the staphylococcus It had been proved to be harmless to tubercle, and the only bacillus to which it had been found to be deadly was that of cholera He could not understand how benzoyl chloride—an extremely irritating compound—could be tolerated —Dr W M Crofton said there were *a priori* grounds for the use of iodoform as a

given intramuscularly, and had, therefore, tried iodoform and benzoyl chloride, and if he had not succeeded in some advanced cases he considered that he had not hurried their end, and since some cases had much improved, he held that he was therefore justified in trying the treatment As to the assumption that iodoform would do no good, he referred to experiments on rabbits which had been injected with the bovine bacillus, and when the disease had developed had been completely cured with iodoform in ether given intravenously This, he considered gave good grounds for its use in human cases He asked if it could be shown that fresh air or sanatorium treatment had ever cured such infected rabbits In a previous paper he had stated that in early cases tuberculin treatment would cure in a good many instances, but that more advanced cases were frequently *unsuitable for tuberculin, and it was, therefore, essential to* use some other method, and iodoform was the best intravital germicide he knew He also found out the other microbes which nearly always accompanied the tubercle bacillus, and used autogenous vaccines made from these microbes He considered that no more accurately scientific methods could be adopted Iodoform with the molecule intact he admitted was a weak germicide but in the presence of pus it was split up with the liberation of free iodine As to coughing and pneumothorax, he said that the slower the injection was given the less would be the coughing, and he had never met with pneumothorax nor heard of such an accident Unless Dr Coleman could suggest something that was better than the present sanatorium treatment he would continue to use the iodoform and the other methods —Dr A R Parsons said that it did not take very long after the introduction of a successful treatment for that treatment to become general, and pointed to salvarsan as a notable recent instance Dewar had in 1903 published a series of cases treated with ethereal injections of iodoform, but notwith*standing this inquiries made throughout 16 of the principal* sanatoriums in Great Britain elicited the fact that 13 of these institutions had never used the treatment —Dr Moorhead said that he did not think that any member should be allowed to remain under the impression that the Academy disapproved of the trial of any method of treatment unless that method was dangerous and he did not consider this method dangerous, and he saw no objection to its trial What should be deprecated was bringing a method of treatment before the public before the profession was satisfied that it should be brought forward Since all desired to arrive at the truth of the matter, he suggested that a certain number of cases should be submitted to independent examination and then treated and compared with other cases which had not been treated, and that the results might then be reported to the Academy This, he thought would demonstrate their desire to arrive at a proper conclusion —Dr T C P. Kirkpatrick said that several of the cases in which the treatment was employed were under his care In no case did the treatment seem to do them any harm, nor did the patients object to it —The President considered that Dr Moorhead s suggestion would get over all the difficulties He suggested that the profession should, as far as possible, avoid doing away with a healthy scepticism, since a dogmatic statement would never get them one step further

---

Society of Medical Officers of Health —A meeting of this society was held on April 11th Professor E W Hope, the President, being in the chair —A discussion upon the Administration of Sanatorium Benefit was opened by Dr Philip Boobbyer, who dealt with the subject as it affected large towns He said that the heart of any scheme was the dispensary which was at once a head office, a clearing house a diagnosis and treatment centre, and an information and instruction bureau for the entire movement As the clinical section of the curative and preventive work must go hand in hand with public health and housing reform it was highly desirable that the dispensary administration should be closely linked with the health and housing departments This union should be centred in the person and office of the medical officer of health In Nottingham the tuberculosis officer had been appointed deputy medical officer of health The incorporation of mothers' and babies' "Welcomes" in any schemes was important They should be used as branch dispensaries, more especially for the examination, sorting, and treatment of children suffering, or suspected of suffering, from tuberculosis —Dr T Eustace Hill, in considering the question from the point of view of the county councils, assumed that they were the proper bodies to carry out sanatorium schemes and not the Insurance Committees or the local authorities All forms of tuberculosis should be dealt with and Insurance Committees should arrange to make the schemes responsible for dependents, because up to 1915 it would be impossible for an Insurance Committee to expend all its funds on insured persons While it was very desirable that there should be cooperation between the county tuberculosis committee and the Insurance Committee, the county committee should be entirely independent of the county health committee and not a subcommittee of it He approved of the tuberculosis *officer being under the administrative control* of the medical officer of health, but considered that the latter officer should not be the chief tuberculosis officer It was essential that there should be cooperation between district authorities and the county councils The former might be responsible for supplying literature, sputum flasks, handkerchiefs, &c, and for disinfection, and the county councils might loan shelters to the district councils He approved of tuberculosis pavilions being erected on the site of existing isolation hospitals and suggested that these should be provided by the authority owning the hospital, the county council paying the cost as rent spread over 30 years the buildings ultimately belonging to the local authority, who should undertake maintenance, nursing, &c, of patients at a charge of about £65 per annum, excluding the cost of conveyance, for which a motor ambulance would be necessary —Dr J R Kaye agreed that existing buildings such as isolation hospitals should be utilised In the West Riding 145 acres of land had been purchased on which acute and advanced cases would be dealt with and where there would be workmen s houses for *discharged cases Referring* to the qualifications of the dispensary nurse he considered that she must be exceptionally tactful and discreet and of a higher standard than a health visitor or school nurse ——At an adjourned meeting of the society, held on April 25th, when Dr W G Willoughby presided the discussion was resumed and Dr S C Lawrence urged the importance of coöperation between the officers of varying authorities He deprecated the supercilious attitude taken up by some county councils towards district councils, although many of the latter had been dealing with tuberculosis administratively for some time, whereas the county councils were altogether without experience in the matter —Mr F F Fremantle favoured the employment of the school nurse and health visitor as the tuberculosis nurse, for it was impossible to separate the curative function from the preventive Although the local authority dealt with prevention, he did not think it would be practicable for the nurse to be paid partly by the county council and partly by the district council.—Dr. W. F. Corfield, from his experience in Colchester, considered that preventive work must be done by the health visitor and treatment nursing by a special nurse, for the reason that many cases would require constant supervision by the latter.—Dr. Willoughby referred to the sentimental objection which there was in some districts to the school nurse dealing with tuberculous cases.—Dr. J. E. Sandilands considered that the dispensary nurses should be on the staff of the medical officer of health.—Dr. P. Caldwell Smith thought that each sanitary authority should have its own municipal dispensary attached to the public health department. He urged that the London County Council should deal with the question of sanatorium benefit for the uninsured.—Dr. A. H. Bygott feared that tuberculosis work might get into the hands of voluntary charitable institutions the standard of which was not particularly high.—Dr. C. Gerard Taylor and Dr. Frank Robinson pointed out the importance of considering the question of sanatorium benefit administration from the point of view of the general practitioner, who just now was suspicious of innovations.—Dr. J. Howard-Jones referred to the difficulties that had arisen in Wales and Monmouthshire owing to the Insurance Funds having been handed over to the Welsh National Memorial for administration, so that another public health authority without any experience had been created.

Bristol Medico-Chirurgical Society.—A meeting of this society was held on April 9th, Dr. Walter C. Swayne, the President, being in the chair.—Mr. E. H. E. Stack in a demonstration on some varieties of Arm Splints advocated the use of a malleable metal anterior angular splint for the treatment of fractures of the forearm. For all injuries about the elbow-joint he had found the position of acute flexion to give the best results, and demonstrated a simple method for putting up an arm in that position. He advocated the early use of active rather than passive movements, the patient being better able to judge the amount of movement possible without risk of damage.—Mr. Charles Corfield, in a paper entitled "What is an Accident?" said that it was impossible to give a satisfactory definition, but that each case must be decided on its merits. He pointed out that such divers conditions as lightning stroke and anthrax had been adjudged to be accidents within the Workmen's Compensation Act; while, on the other hand, a case of sewer-gas poisoning was not so decided.—Dr. G. Parker suggested that as a medical man was only expected to use ordinary skill and care, so an accident should only be so adjudged if it would similarly have affected a person in an ordinary state of health.—Mr. W. Stuart V. Stock related two cases in which death occurred two or three days after an operation from Heart Failure in patients the subject of fatty heart, although they had shown no bad signs during a prolonged administration of an anæsthetic.—Mr. A. Rendle Short, in a paper on the Nature of Surgical Shock, pointed out that the two great objections to the generally accepted theory of Crile and Mummery, that it was due to vasomotor centre fatigue, were that the peripheral vessels were found to be constricted and not dilated; and also that the centre could be shown experimentally not to be exhausted. He had examined the venous blood of a number of patients the subject of shock, but had been unable to confirm the theory of Yandel Henderson that shock was due to a deficiency of CO_2 in the blood. His own view was that the symptoms were due to a loss of fluid from the blood which apparently passed out into the tissues and was possibly squeezed out by vasomotor reflexes.

Leeds and West Riding Medico-Chirurgical Society.—A clinical meeting of this society was held on April 18th, Dr. J. Dobson, the President, being in the chair.—Dr. G. W. Watson showed a case of Heart-block occurring in a man aged 60. For some weeks the condition had been looked upon as being one of complete heart-block. The pulse varied from 22 to 26 per minute, and was regular in rate and force. There were practically no symptoms beyond dyspnœa on exertion and dizziness. He was treated by iodide of potassium in 7 grain doses with small doses of liquor morphinæ, three times a day. After a few days the pulse-rate jumped to 44 per minute, and afterwards to 72–76 per minute. Whenever the pulse-rate altered in frequency, the patient experienced a momentary sensation of faintness.—Dr. Wardrop Griffith exhibited a series of polygraph records of this case and also tracings of three other cases of heart-block under his care, one of which he showed to the society. Dr. Griffith also showed amongst other cases a woman in whom he had diagnosed Patency of the Ductus Arteriosus, and in whom the condition was complicated by acquired mitral disease.—Dr. A. L. Whitehead showed a case of Congenital "Pit" at the right macular region, and explained its developmental origin.—Dr. R. A. Veale showed a man with an Arthritis of the Elbow-joint of doubtful causation, which had given rise to paralysis of the ulnar nerve. Rapid improvement was taking place under massage and electricity. Dr. Veale also showed a case of Hydroa Æstivalis occurring in a boy aged 4 years. He pointed out the seasonal incidence of the disorder, and mentioned its rare occurrence. He also described the mode of onset, and discussed the question of treatment and prognosis.—Dr. C. W. Vining showed two cases of Parasyphilitic Disease of the Nervous System. In his remarks Dr. Vining emphasised the importance of accurately differentiating between tertiary syphilis and parasyphilis. In the former case treatment was necessary and usually effective; in parasyphilis no treatment, as a rule, was of any avail.—Cases were also shown by Dr. T. Churton, Dr. W. H. Maxwell Telling, Mr. R. Lawford Knaggs, Mr. H. Collinson, Dr. J. B. Hellier, Mr. J. A. Coupland, Mr. G. Constable Hayes, and Mr. Alexander Sharp.

Liverpool Medical Institution.—A meeting of this society was held on April 17th, Mr. F. T. Paul being in the chair.—Specimens were shown, and these were discussed by Mr. Paul, Mr. G. C. E. Simpson, and Mr. Damer Harrisson.—Mr. F. A. G. Jeans read a note on Desmoid Tumours, with a report of a case and the specimen and microscopic section. The term, he said, was applied to tumours consisting of fibrous tissue growing from muscle and fascia, especially in the lower part of the abdominal wall. It was supposed that they might originate from inflammation, hæmorrhage, or from friction. They sometimes appeared in cicatrices. Mr. Lockwood had described them and had recommended that they should be treated as suspect of malignancy. The specimen shown was of about the size of a pigeon's egg, and had occurred in a fat, healthy woman, aged 22, in the region of McBurney's point, and had been noticed for three years, and was slowly growing and becoming painful.—Mr. Paul said the tumour was of a class of spindle-celled tissue which might become malignant, but when removed in time would not recur.—Dr. J. Murray Bligh read a note on the Tuberculin Reaction. He had used Koch's old tuberculin in 60 cases, all children, half of whom had no symptom of tuberculosis, and half with evident tubercular disease. Dr. Bligh's general conclusions were that the tuberculin reaction was of no practical value for diagnostic purposes. He mentioned that in 9 cases of chorea tested, 8 gave a positive reaction to human or bovine tuberculin or to both, and after the chorea was cured they gave negative reactions.—Professor J. M. Beattie said that a positive reaction in cases where there was no evident disease might arise from tubercular disease being present in the tonsils. He had found this in cases where there was no other tuberculosis. The cases of chorea might give a reaction, as sore-throat was a common accompaniment of chorea, and it might be tubercular, and so explain the high percentage of reaction in chorea cases.—Dr. N. Percy Marsh had found after extensive use of von Pirquet's method that it was of little value, but in children under one year a positive reaction had invariably meant a fatal result.—Dr. C. O. Stallybrass, Dr. C. Rundle, and Professor T. R. Glynn also spoke, and Dr. Bligh replied.

Hunterian Society.—The annual meeting of this society was held on April 23rd, Mr. A. H. Tubby, the President, being in the chair. The officers for the next session were elected.—Dr. A. Graham-Stewart (Margate) read a paper founded on his winning essay—On the Diagnosis and Treatment of Early Hyperpiesis and Arterio-sclerosis. He pointed out the necessity of getting these cases early—before they had gone on to very high pressures and before there was much structural change in the vessels or heart. By so doing the progress of the disease might often be held in *statu quo*. He then urged the necessity of measuring the blood pressure in all cases of illness. Apart from the etiological factors as mentioned in text-books on medicine, Dr.

Graham-Stewart brought forth others as being frequently more [illegible] to be a prominent cause, and the use of vaccine therapy for the relief of hypertonus was discussed. The experiments of Manouélian were brought forward as strong proof of the auto-inoculation theory, as propounded by the author of the paper. The earliest symptoms of hyperpiesis and arteriosclerosis were then touched upon—symptoms which call attention to the vascular system—and a method of differentiating between an accentuated aortic second sound and an accentuated pulmonic second sound was described. Dr. Graham-Stewart also showed a Bowles's stethoscope, and pointed out its advantages over the ordinary instrument in general use. Stress was laid upon the danger of employing nitrites indiscriminatingly and in every case, and a list of symptoms was given warranting their employment. The speaker also pointed out that there were two types presenting hyperpiesis—the physiological and the pathological, and that the former group required a raised pressure to get on at all. He then touched on the treatment of "acute" cases—cases with pressures up to 300 mm. of mercury—and stated that the use of digitalis was not contraindicated provided other symptoms called for its employment, as digitalis had no power of raising an already high blood pressure; that [illegible] by the President, Dr. Purves Stewart, Dr. A. O. Jordan, Dr. F. Howard Humphris, Dr. A. S. Currie, and Dr. A. Westerman, after which the society's silver medal and certificate were presented to Dr. Graham-Stewart by the President.

Reviews and Notices of Books.

The Surgery of the Skull and Brain. By L. BATHE RAWLING, F.R.C.S. Eng., Surgeon with Charge of Out-patients, Senior Demonstrator of Practical Surgery, Demonstrator of Operative Surgery, St. Bartholomew's Hospital; late Hunterian Professor, &c. London: Henry Frowde and Hodder and Stoughton. 1912. Pp. 340. Price 25s. net.

THE surgery of the brain is one of the more recent advances of our art, for, except for the treatment of fracture of the skull, it cannot be said to date back more than a few years. Much of what we know is so very new that it has hardly found its way into the text-books as yet, and there is room for a work such as this in which the very latest contributions to this branch of surgery are presented to the profession.

The book commences with an account of the topography of the skull and brain. This is brief, but sufficient for general purposes. There are many points in the special technique of the surgery of the brain, and success in cerebral surgery depends not a little on attention to these points; the chapter on the technique is, therefore, important and contains many hints of value. The author has devised a modification of Cushing's tourniquet which has served him very well; it consists of a metal band which encircles the head and prevents hæmorrhage from the vessels of the scalp which may be troublesome. It appears likely to be useful. The succeeding chapters deal with the various lesions of the skull and brain. In speaking of the treatment of hydrocephalus, the author expresses the following opinions: "While recognising that internal hydrocephalus usually demands surgical interference, it is only *in some few cases that material benefit results*"; and "The operation which promises the best results, combined with the least risk to the patient's life, is that described as ventriculo-subdural drainage." With these opinions we are disposed to agree.

The escape of cerebro-spinal fluid from the ear, nose, or mouth is usually described in text-books on surgery as a common symptom of fracture of the base of the skull, but the author states—and in this he is in accord with others who have specially discussed this matter—that the escape of cerebro-spinal fluid is comparatively rare, for it does not appear to occur in more than about 5 or 6 per cent. of all cases of fractured base. Perhaps the most important section in the book is that dealing with tumours of the brain. Here we find a very clear description of the tumours which occur within the skull, of the symptoms to which they may give rise, and of the treatment which may be adopted. Mr. Rawling finds that his statistics give a lower mortality than was possible a few years ago. He is inclined to think that the average mortality may be put at less than 20 per cent. In this connexion he makes a statement that all young operators on tumours of the brain should lay to heart. He says: "The great secret in operating on a brain tumour lies in knowing when to terminate the attempt at removal of the tumour and when *to rest content with a pure* 'decompression.'" So long as surgeons will persist in burrowing into the brain-substance for a supposed subcortical tumour, so long will the mortality remain high.

The book is well supplied with illustrations, and it gives a very readable account of an important branch of surgery. The high quality of the printing is guaranteed by *saying that the work is one* of the Oxford Medical Publications.

Diseases of Women: A Clinical Guide to their Diagnosis and Treatment. By GEORGE ERNEST HERMAN, M.B., F.R.C.P. Lond., F.R.C.S. Eng., Consulting Obstetric Physician, London Hospital; assisted by R. DRUMMOND MAXWELL, M.D. Lond., F.R.C.S. Eng., Assistant Obstetric Physician to the London Hospital and Physician to Queen Charlotte's Lying-in Hospital. With 8 colour plates and 292 figures in the text. London, New York, Toronto, and Melbourne: Cassell and Co., Limited. 1913. Pp. 899. Price 25s.

IN preparing a new edition of his work on diseases of women Dr. Herman has enlisted the services of Dr. Maxwell to help him, more particularly in the parts relating to operative technique. There is little need for us to praise a book which is now in its fourth edition and which has proved a signal success from its first appearance. Dr. Herman's book is, in our opinion, one of the best of the text-books on diseases of women, and the present edition presents a happy blending of the old and the new teaching of this subject which augurs well for its continued success. The number of pages is not very different, but the format has been altered so as to obtain a larger and a better page, a number of new illustrations have been introduced into the text, and there are eight new colour plates. Some of these are extremely good, especially the two illustrating carcinoma of the portio vaginalis and interstitial hæmorrhage into the ovary, but that purporting to represent an erosion is disappointing.

The whole book has been very thoroughly revised. In the chapter on chronic abdominal pain we notice a new section on bacillus coli infections of the urinary tract. In the treatment of prolapse of the uterus Tod Gilliam's operation and that for making a sling of the round ligaments are described. No doubt in the next edition Mayo's valuable modification of the former operation will find a place. We notice that the terms ventro-fixation and ventral fixation are both used, but that there is no allusion to ventral fixation in the index. It would be as well to adopt one term and one only, and ventro-fixation seems the better of the two. In the treatment of cases of adherent retroflexion there is a description with a good illustration of the operation of salpingostomy. The description of the operation for a ruptured tube has been revised and improved, as has also the description of vaginal hysterectomy. We must confess we are disappointed with the account of Wertheim's operation. The authors seem to us to lay unnecessary stress upon the closure of the vagina below the growth so as to avoid the danger of sepsis and infection by the cancer cells, to the neglect of the necessity for removing as large an amount as possible of the parametrium. From reading this description the novice would certainly not find the ureters easily, and inasmuch as there is no mention of Wertheim's special forceps for the parametrium, nor any account of the best method of clamping and dealing with the parametrium, the operator, depending on the manual, might get into difficulties. The uterine artery is recommended to be tied as far out as possible, but no mention is made of the necessity for preserving the superior vesical artery, or for clamping or tying the uterine veins, which so often lie beneath the ureter, as well as over it. Very probably the account is not intended to be more than an outline, but even in that case the very casual reference to "the ligaturing off any masses of paravaginal cellular tissue" is misleading, inasmuch as, in our opinion, this is one of the most important of all the steps of the operation.

In the section on the sterilisation of women the authors say that it is proper advice in the case of women who are the subjects of nervous diseases which would be aggravated by pregnancy or child-bearing, or which would be transmitted to their offspring, to recommend sterilisation; but what these diseases are must be decided after consultation with a specialist. In a general text-book for students it is, we think, advisable to give, at any rate, some indication as to what these diseases are; it would be difficult to name many diseases in which such advice would be proper. The section on kraurosis vulvæ and leukoplakia has been revised in view of the work of Comyns Berkeley and Bonney on these subjects. Dr. E. Reginald Morton has contributed sections on the use of the X rays and radium in cervical cancer and in pruritus vulvæ, and the use of a pencil of frozen carbonic acid in urethral caruncle. We are surprised to find no mention of the treatment of uterine fibroids by radiotherapy.

The book as a whole is very good and a credit to its authors.

Manual of Medicine. By A. S. WOODWARK, M D. Lond., M.R.C.P. Lond., Junior Curator of St. Bartholomew's Hospital Museum; Physician to the Royal Waterloo Hospital, &c. London, Edinburgh, and Glasgow: Henry Frowde and Hodder and Stoughton. 1912. Pp. 409. Price 10*s*. 6*d*.

THE author explains in his preface that "in contributing this little book to the enormous mass of medical literature at present in existence" he hopes to fulfil a twofold purpose—that of supplying a vade-mecum for the student clerking in the wards or out-patient department and that of a convenient reference-book for the busy practitioner. After a perusal of the volume we believe that to a member of the profession engaged in general practice this manual would be of considerable use, enabling him in a short time to refresh his memory as to the salient features of any particular disease. If a student would utilise the book as an addendum to a larger and more detailed work, then he also might find it of considerable value as giving a clear summary of the chief points in regard to the etiology, pathology, symptomatology, and treatment of any malady, but he would have to resist the temptation of letting it replace a more comprehensive text-book.

Dr. Woodwark has succeeded in condensing a large amount of information into a comparatively small space. The manner in which the subject matter is arranged renders any reference easy, and for the most part both the theoretical and practical considerations are fully up to the more modern views.

Brain and Spinal Cord. A Manual for the Study of the Morphology and Fibre-tracts of the Central Nervous System. By Dr. Med. EMIL VILLIGER, Privat-dozent in Neurology and Neuropathology in the University of Basel. Translated by GEORGE A. PIERSOL, M.D., Sc.D., Professor of Anatomy in the University of Pennsylvania. From the third German edition. With 232 illustrations, many of which are coloured. London and Philadelphia: J. B. Lippincott Company. 1912. Pp. 289. Price 16*s*. net.

Professor Piersol's translation of this well-known German work is welcome, for there is a clearness in the manner of presentation in this treatise which is not by any means universally present in descriptions of the brain and spinal cord. The book should be a real help to the student, for it bridges over in a satisfactory manner that gap which all too often exists in the student's knowledge between the arrangements of the tracts of the central nervous system, as demonstrated by the physiologist, and the gross structure of the brain and cord as displayed by the anatomist. For this reason alone it is a valuable work for the student, but it also possesses the merit of giving a short but clear account of the morphology and development of the central nervous system.

The illustrations are excellent, being that satisfactory blend of a diagrammatic clearness and an actual accuracy which makes the ideal of anatomical representation. Colour has been employed throughout with judgment and restraint, clearness of definition rather than attractive adornment having been the obvious guiding principle. A selected bibliography of the most important contributions to the literature has been added, and for the specialist references to more extended bibliographies are appended.

Handbuch der Nervenkrankheiten im Kindesalter. Von Prof. L. BRUNS, Oberarzt d. Hannoverschen Kinderheilanstalt; Prof. A. CRAMER, geh. Med.-Rat, Direktor d. kgl. Univ. Klinik f. psych. u. Nervenkrankh. in Göttingen; Prof. TH. ZIEHEN, geh. Med.-Rat, fr. Direktor d. psych. u. Nervenklinik d. kgl. Charité in Berlin. Mit 189 Abbildungen im Text und 3 Tafeln. Berlin: S. Karger. 1912. Pp. 980. Price 30 marks.

IN this imposing volume of almost a thousand pages the attempt has been made to produce a complete and authoritative text-book of nervous diseases as they affect children, and the names of the authors are a guarantee of the thoroughness and accuracy of the book as a whole. Some of the subjects are handled at considerable length: 40 pages are devoted to hysteria in childhood and 90 to epilepsy. Such diseases as are confined to or appear in early life—e.g., Werdnig-Hoffmann paralysis, Little's disease, infantile cerebral hemiplegia, to mention only a few—are excellently done. Rare diseases receive due attention, while common conditions, such as chorea, meningitis, and so on, are described in an exhaustive manner.

In a work of this size it is, perhaps, inevitable that there should be a certain amount of inequality in the contributions. The chapter on intracranial tumours is in the main satisfactory, yet in the diagnosis and symptomatology of tumours of the temporal lobe, corpus callosum, third ventricle—to refer to these only—we miss various points that might well have been included. In the chapter on chorea there is no reference to the occurrence of an extensor response, and no description, as far as we can see, of the choreic hand. In the article on poliomyelitis the most recent discoveries, in a text-book of the pretensions of the one under review, might have been referred to a little more generously.

There are a good index and valuable bibliographical tables throughout which will be of great service to the neurologist While the majority of the pathological illustrations are good, this cannot be said for all the clinical ones, some are woodcuts which have done duty for a generation now, and others are inadequate for the purpose intended The volume, however, contains an immense amount of information, methodically arranged and well written, and we are sure it will be greatly appreciated by all interested in the study of diseases in children

---

Leitfaden der Praktischen Kriegs Chirurgie Von Dr WALTER VON OETTINGEN, Chirurg in Berlin-Wilmersdorf, s z Chefarzt des Livländischen Feldlazaretts vom roten Kreuz im Russisch Japanischen Kriege Dresden und Leipzig Theodor Steinkopf 1912 Pp 377 Price, bound, 9 50 marks

THE surgical art in war has an importance that can hardly be overrated, for modern methods of treatment make it possible to do much more for the wounded than could be done even 40 years ago It is now recognised that the coated bullet does as a rule far less harm to the soft tissues than its predecessors did, which were larger and moved with a less velocity, and it has been found possible in many cases within a few weeks to replace a wounded man in the firing line if he has been treated in accordance with modern methods Therefore, it is clearly of the greatest importance, even from a military point of view, that the surgery of war should be cultivated to its full extent Many manuals have appeared on this subject, and this is one of the most recent, and also so far as it goes one of the best that have yet appeared The author has had experience in the war between Russia and Japan, and the book is evidently largely based on the practical knowledge thus obtained

The book begins with an account of the modern rifle and of the bullets generally employed, then the forms of wounds produced by these projectiles are described An account is also given of the wounds resulting from the explosion of mines and from other injuries which may occur in war, even though not the result of firearms The second section treats of the mode of healing of wounds, the importance of asepsis, and the modes of disinfection that can be employed on the field of battle The most convenient forms of dressing for field use are described The general treatment of wounds on the field, and of shock and hæmorrhage, general and local anæsthesia, the nursing of patients in war, their food, and their transport to base hospitals are considered in order The second half of the book is devoted to a description of injuries of special parts of the body and the suitable treatment for them

The book contains all that can reasonably be expected in the small space occupied, and it should prove very useful to all those connected with the treatment of the wounded in war, not only to the junior medical officers, but also to nurses and aids

---

The Protein Element in Nutrition By Major DAVID MCCAY, M B R U I, M R C P Lond, I M S, Professor of Physiology, Medical College, Calcutta Illustrated London. Edward Arnold 1912 Pp 216 Price 10*s* 6*d* net

THE aim of the general editors of the International Medical Monographs Series is to set men of ripe experience and proved merit to sift the enormous output of modern research, each in his own department, and to give us the result in a balanced, concise, and accurate form This aim has certainly been attained in handing over to Professor McCay a subject of such importance as the estimate of the proper amount of protein necessary for nutrition The author has had exceptional opportunities of studying on a large scale the physique and food of many of the natives of India, and of investigating on a large scale the chemical intake and output of prisoners in Indian gaols His researches have extended over many years, and this volume is partly an aggregation of important papers already published The tone of argument exhibited is not at all aggressive, and the language is far more moderate than that often employed in discussions on dietetics This very moderation serves to give force to a vast array of details skilfully marshalled, and to destructive criticism, which is occasionally employed

The main argument is that the supposition that the natives of India are entirely, or even largely, vegetarians is untrue, and that when they are so it is only under the pressure of poverty A huge mass of careful matter, dealing with the staple foods of the Tropics, is given in support of this view The chief areas of low protein dietaries in India are found in Madras and Lower Bengal, and both areas show a lower average of physical development than is found elsewhere. Professor McCay refutes carefully all other alleged causes except that of food In the maintenance of his thesis the whole question of protein dietaries, the necessity and importance of protein, its metabolism, and the effects of low protein dietary in the Tropics, are very fully considered The book, therefore, contains an enormous mass of interesting detail to students of the principal debated questions of diet, and the information is thoroughly well arranged Professor McCay again takes up the cudgels against Professor Chittenden, though the last word has probably not been said on either side The problem of the relation of the amount of nitrogen taken in to that excreted is not so simple a one as has been often asserted The quality of the resultant tissues may be as important as the quantity estimated by mere weight That an animal may be fed so as to increase its weight and not show tissues of valuable quality has been long recognised, and in the volume before us the same problem as applied to man is discussed carefully Some highly interesting observations on the renal pathology of the grain fed Bengali are quoted in the chapter dealing with the physique and expectation of life of those races and Eurasians

The Bacteriology of Surface Waters in the Tropics By WM WESLEY CLEMESHA, M B Vict, D P H Calcutta Thacker, Spink and Co London E and F N Spon 1912 Pp 161 Price Rs 7 8

BACTERIOLOGISTS, and more particularly those who are engaged upon the guarding of our water supplies from pollution, will find this admirable essay well worth study, inasmuch as it sets forth the reasons why a standard adopted in England does not apply to the waters of tropical countries, where the germicidal properties of sunlight are a very potent factor In this country, for example, when organisms are found in a water that give certain fermentative reactions they would be considered more objectionable than others which did not The deduction is probably correct, but, as the author shows, this attitude would condemn nearly every drop of drinking water in India with probably no justification in the greater number of instances In the classification of organisms a much more satisfactory method from the point of view of the water bacteriologist is to divide them according to their ability to live in water exposed to sunlight. Natural processes of self purification make it incumbent to study the kind of organisms, rather than their number, in order to arrive at a satisfactory judgment A concrete case is quoted Two separate organisms of the "coli group" are present in water, one of which may be found in nature to multiply in water or to remain at the bottom of lakes for long periods But the second organism may be clearly shown to disappear in a few days The significance of these two organisms would clearly be different when looked at from the point of view of their presence in any sample of water This illustration affords an example of the value of a careful study of the natural phenomena of self-purification which discloses important facts relative to the life-history of individual species of fæcal organisms.

The classifying of organisms, on the other hand, into artificial groups according to their action on certain sugars conveys nothing of practical value. Classification, however, for the purpose of description is necessary, but what the author insists upon is that it is not logical to conclude that because all organisms ferment the same sugar it follows that they possess similar characteristics in other respects or behave similarly when passed into water and subjected to natural forces. He shows, in fact, that this is not the case, and the experimental evidence deduced is based upon such extremely careful work as to leave very little doubt that he has established his point. Of course, it may be asked why English methods have given such satisfactory results as to lead to their general adoption. To which question the author replies that in England practically any trace of pollution is dangerous. There is not time for any very elaborate self-purification to go on in most natural sources, and it is probable that a more detailed examination on the lines suggested by the author and his colleagues of the process of storage would show that the results obtained in England resemble those in India. It is, however, obvious that in questions of determining whether water is fit to drink or not the standard should err rather on the side of severity than on that of leniency.

The observations recorded in this book add very valuable material to our knowledge of the flora of water-supplies, and particularly in regard to their life-history and pathological significance.

Text-book of Ophthalmology in the Form of Clinical Lectures. By Dr. PAUL ROEMER, Professor of Ophthalmology, Greifswald. Translated by Dr. MATTHIAS LANCKTON FOSTER. Vols. II. and III. London: Rebman, Limited. 1912–13. Pp. 277–571, 573–896. Price 10*s*. 6*d*. each net.

Dr. Foster has brought his task of translating Professor Roemer's text-book of ophthalmology to a successful conclusion, and the work is now available for English-speaking students in a thoroughly good translation. We have already reviewed the original work and the first volume of the translation[1] and pointed out the type of student for whom they are likely to be specially useful. The volumes are admirably printed and illustrated.

Du Strabisme. By Dr. PIERRE LAGLEYZE, Professor of Opthalmology in the University of Buenos Aires. Paris: Jules Rousset. 1913. Pp. 409. Price 15 francs.

THIS work consists chiefly of an account of all the cases of squint which have been treated by the author, his methods of treatment, and a discussion of the pathogenesis of the complaint on familiar lines. Little attention is directed to orthoptic treatment, and the operative measures advocated are those generally in use.

LIBRARY TABLE.

Clinical Methods for Indian Students: A Guide for Students and General Practitioners in India in Diagnostic and Therapeutic Methods. By G. T. BIRDWOOD, M.D. Cantab., Major I.M.S., late Principal, Medical School, Agra; and Foreword by J. R. ROBERTS, F.R.C.S. Eng., C.I.E. Calcutta: Thacker, Spink, and Co. 1913. Pp. 171. Price Rs.2.8.—Major Birdwood's "Clinical Methods," we believe, will find a sphere of utility far beyond the confines of India. He has collected into one convenient handbook the clinical tests and main diagnostic laboratory processes which, for the most part, have to be sought in not always readily accessible books or scientific periodicals. Many of them, of course, are matters of general knowledge; but even these, the practitioner once well versed in the details, when he has occasion to revert to them only very infrequently, will probably have forgotten, and may be thankful for a brief categorical description of them; while many are of less common knowledge, though well established. The more the practitioner with a sound laboratory education can learn to rely on himself for those clinical tests that are not too complicated and do not need too elaborate an armamentarium for their performance, the better equipped he will become as a diagnostician, for clinical examination and laboratory examination are complementary the one to the other, and sound judgment comes not from regarding either separately, but from a judicious correction of each by the other. Among the subjects dealt with—the processes number 68 in all—are examinations of the blood, including cultivations and processes necessary in malaria, kala azar, tropical ulcer, typhoid and fevers of uncertain origin, method of examination for various pathogenic micro-organisms, examination of rats for plague, examination and identification of mosquitoes, examination of lochia, urine and fæces for germs; protozoa, and eggs of worms, and of hydatid fluid, lumbar and pleural puncture, estimation of the opsonic index and preparation and dosage of vaccines, the use of tuberculin and leprolin and of antitoxic sera, the taking of swabs, anaphylaxis, snake-bite and its treatment, salvarsan and syphilis, how to embalm a dead body, and notes on the use of the microscope, stains, and general laboratory processes. Each subject is dealt with in concise paragraphs, each step of any procedure being numbered in order of performance. The book is interleaved for notes. While some of the difficult processes—e.g., the preparation of vaccines and opsonic index calculations, Wassermann's test, and so forth—are best left, whenever possible, to the trained pathologist, a general knowledge of the method pursued will yet be an advantage to the practitioner. We would suggest that the plan adopted in section No. 5, on the counting of red blood corpuscles—viz., the enumeration of all the requisites for the operation—might with advantage be adopted much more generally through the book, but that it should precede, instead of following, the article to which it refers More careful proof-reading would also be an advantage in future editions. It is true most of the errors we have noted are in the spelling of proper names and are not of practical importance; but their frequency leads to an uncomfortable feeling of insecurity, lest errors should be present in more important matters. We have not noted any such, however.

The Energy System of Matter. A Deduction from Terrestrial Energy Phenomena. By JAMES WEIR. With 12 diagrams. London: Longmans, Green and Co. 1912. Pp. 200. Price 6*s*. net.—The author had better speak for himself, and this he does, after an intimate study of natural phenomena, in the following words: "I have reached the conclusion that every physical phenomenon is due to the operation of energy transformations or energy transmissions embodied in material, and takes place under the action or influence of incepting energy fields." It appears that the main principles on which the present work is founded were broadly outlined in the same author's "Terrestrial Energy" in 1883, and also in a paper in 1892. Obviously he is distressed as to the present position of the problem that has attracted his attention. "Day by day it becomes more evident that not one of the many existing theories is adequate to the explanation of the known phenomena." The field of energetics is specially under his ban. Speculative methods are still rampant, he states, finding that they have become the fashion, or rather the fetich, of modern science. "It would seem that no experimental result can be of any value until it is deductively accommodated to some preconceived hypothesis, until it is embodied and under the sway of what is practically scientific dogma." Fortunately, the author does not propose "to add another thread to the already tangled skein of scientific theory." We express our concurrence. Those of our readers who are interested in the "principles of inception" may perhaps read the author's concluding sentence: "The finger of Nature ever points to closed energy circuits, to the earth as a complete and conservative system in which energy, mutable to the highest degree with respect to its plurality of form, attains to the perfection of permanence in its essential character and amount."

[1] THE LANCET, Oct. 26th, 1912, p. 1156.

Studio su la Morte Apparente e la Morte Reale. By Dr. A. CREAZZO. Rome: Loescher and Co. 1913. Pp 184. Price 3 lire.—From time to time both in the English and foreign press the public are treated to sensational accounts of persons supposed to have been buried alive. The medical profession as a whole is incredulous of the danger of apparent death, but Dr. Creazzo considers it none the less our duty to investigate the subject thoroughly and find some certain method of proving that death has really taken place in order to demonstrate after years of trial that the danger is purely imaginary. If this can be done a great service will have been rendered to humanity, and Dr. Creazzo has contributed *in not a small measure to it. In this little* work the author discusses such questions as latent biological activity, the autonomy of the various organs and functions, latent life in the higher organisms, the stages of death, the persistence of life in apparent death, and the phenomena of residual vitality. He reports some authentic and interesting cases of apparent death, and reviews the classical and secondary signs by which death is usually affirmed; among these, however, we find no mention of alterations produced in the rotundity of the pupil under digital pressure. He considers it proved that since the manifestation of life is to be found in intracellular bio-chemical processes, the whole individual does not die at a given moment, but the organism is gradually extinguished. Hence everyone who dies passes through a state of latent life, subdivided into apparent, relative, and intermediate death. The author believes in residual vitality and that there arrives a moment in which the individual ceases to have that small modicum of life which, theoretically at least, would be sufficient to reanimate it. Dr Creazzo endorses the opinion expressed by Brouardel, that we have no sign or combination of signs which enable us in all cases to affirm with scientific certainty that death has taken place. His remedy consists in a more extensive and general application of the methods of Icard, especially the intravenous injection of fluorescin, which tinges the tissues if the circulation is still present, and the insertion into the nostrils of filter paper saturated with neutral acetate of lead, which blackens from the products of putrefaction. Other methods are described, but the two mentioned have the merit of simplicity and universal application in removing from the public mind the spectre of premature burial.

SUNSHINE HOME, HURSTPIERPOINT.—H.R.H. Princess Alexander of Teck on April 23rd visited Hurstpierpoint, a township at the foot of the Southdowns in Sussex, and there laid the foundation-stone of the chapel of the Sunshine Home. This institution began ten years ago as a small convalescent hospital with six beds. It was enlarged in 1905 and again in 1908. The Home is essentially a home of recovery for surgical cases (women and girls only) which are passed on from hospitals.

THE FINAL REPORT OF THE ROYAL COMMISSION ON UNIVERSITY EDUCATION IN LONDON.

II.[1]

PART III. of the report deals with the application of the principles of government for the University whose enunciation closed Part II. The financial and educational control of any constituent colleges and university departments is considered, as well as the constitution and general powers of the faculties and their relation to these bodies. The various faculties are then discussed: a table in each case shows the present teachers in the faculty and the institutions in London at present suitable for inclusion in the University as constituent colleges in the faculty. Constituent colleges may be established by the University, but any existing institution engaged in doing University work in one or more faculties, which is strong enough to comply with conditions of incorporation, and willing to transfer the financial and education control in respect of such faculties to the University, may become a constituent college to the indicated extent. The salaries of the professors and readers in the various faculties are set down at £600 to £1000 and £300 respectively.

The following is a summary of the recommendations in respect of the Faculty of Arts:—

[illegible] teachers [illegible] management.

Bedford College should become a constituent college in the Faculty of Arts, subject to its compliance with the conditions as to university [illegible] the reconstitution of [illegible] establishing the new [illegible] with the University [illegible] for maintenance is [illegible]

The recommendations in respect of the Faculty of Science are no less succinct. The Faculty, it is suggested, should have an exactly similar constitution to that of the Faculty of Arts, but the payment of the professors is indicated upon the higher scale. The head of every department in a constituent college or university department in the Faculty shall be either the professor or the reader in the subject. The following are the other main recommendations:—

The Imperial College of Science and Technology should become a constituent college of the University in the Faculty of Science, provided the University is given the necessary educational and financial control [illegible]

King's College for Women should as soon as possible be constituted the University Department of Home Science and Economics or of Household and Social Science, and should, if possible, be placed in the

---

[1] No. I. was published in THE LANCET of April 26th, 1913, p. 1121.

Bloomsbury district in close proximity to the central university buildings and to the suggested new site for King's College.

The Royal Veterinary College should become, if possible, the University Department of Veterinary Science, subject to its compliance with the conditions as to university management we lay down, and to its abandoning the teaching of chemistry, biology, and physiology (including histology). Additional income is needed as soon as possible in order to make the professorships of medicine and surgery full-time appointments.

The Brown Animal Sanatory Institution should if possible be moved into close proximity to the Royal Veterinary College, and should in that case be placed under the management of the same committee as the Royal Veterinary College.

The Goldsmiths' College should continue to be a day training college for elementary school teachers, giving a two years' course of university training for the certificate of the Board of Education, but not preparing its students for degrees. Subject to the approval of the London County Council it might also continue to maintain the present school of art. It should abandon its present lectures and classes in science and in technological subjects.

The School of Pharmacy and the Finsbury Technical College should not be formally connected with the University.

With regard to Bedford College, the East London College, and the Birkbeck College, the recommendations are exactly the same as they were in the case of the Faculty of Arts.

The Faculty of Technology is considered at some length, very definite reasons being given for the views of the Commissioners that the foundation of a separate University of Technology, with the existing Imperial College of Science and Technology as its nucleus, would be a mistaken proceeding. The Commissioners remind us that the newly constituted University will differ from the existing one in many main features, and hope in their recommendations to satisfy both those who claim independence for the College of Science and those who do not wish to see the College separated from the University.

The main recommendations in respect of the Faculty of Technology are as follows:—

The Faculty should consist of the vice-chancellor, the university professors, the honorary and associate professors, the university readers and the honorary and associate readers in charge of departments dealing with subjects of study in respect of which no university professorship is in existence, and of such other teachers and officers appointed by the University as the Faculty may coöpt. The Faculty should also include persons with special scientific knowledge of the industries and professions with which the Faculty has relations. The numbers and mode of selection would be decided by the Senate after report by the committee referred to in the next recommendation.

The present Faculty of Engineering should be merged in a Faculty of wider scope, which should include all the instruction given by the University in Science as applied to industry and should be called the Faculty of Technology.

There should be a statutory committee of the Senate, entitled the Committee for Technology, to be entrusted, subject to the supreme control of the Senate, with the conduct and management of all the departments of the Faculty within the several constituent colleges of the University.

The Committee for Technology to be appointed annually would consist of the vice-chancellor *ex officio;* the rector of the Imperial College of Science and Technology *ex officio;* other persons, a bare majority of whom would be appointed by the Senate, including at least two representatives of the delegacies of University and King's College respectively; the remainder being appointed by the governing body of the Imperial College.

The Committee for Technology should always consist as to at least three-fourths of its members of men of affairs and persons with special scientific knowledge of the professions and industries concerned. A committee of 15, including the two *ex officio* members, would be consistent with this constitution and suitable in size for the purposes in view.

Subject to the approval of an annual budget and report by the Senate. the Committee for Technology should have control of all the funds and buildings available for the Imperial College and of all the funds and buildings at present available for the teaching of engineering in University College and King's College, together with any additional funds and buildings that may be assigned to it by the Senate.

The departments of engineering at University and King's Colleges, or at other institutions hereafter admitted as constituent colleges in the Faculty of Technology, should not be modified, abandoned, or transferred without giving the delegacies of those colleges the opportunity of being heard by the Senate of the University, whose decision in the matter will be final.

The Committee for Technology should submit its annual budget and report to the governing body of the Imperial College, and the Senate should consult the governing body before approving or rejecting them.

The existing arrangements for the management of the several constituent colleges of [illegible] gy should continue until th[illegible] the Committee for Techno[illegible] university professorships and readerships should be made by the Senate on the [illegible] has been advised by boards of advisers [illegible] that at present followed by the Senate [illegible] essorships.

The Imperial College of Science and Technology should become a constituent college of the University in the Faculty of Technology subject to the provisions laid down.

University College and King's College should become constituent colleges in the Faculty of Technology subject to the same provisions. But in order to fit them to fill this position adequately additional income is required for the establishment of university professorships and readerships.

The arrangements for headship of departments and salaries are similar to those in the previous two faculties, and the East London College is recommended for a constituent college as soon as it can raise the necessary funds, provided it will comply with the necessary conditions of university management.

The recommendations with regard to the Faculty of Economics are as follows:—

1. The faculty should consist of the vice-chancellor, the university professors, the honorary and associate professors, the university readers, and the honorary and associate readers in charge of departments dealing with subjects of study in respect of which no university professorship is in existence, and of such other teachers and officers appointed by the University as the faculty may coöpt. The faculty may also include persons with special knowledge of the professions and callings with which the faculty has relations. The numbers and mode of selection would be decided by the Senate.

2. The head of every department in a constituent college or university department in the Faculty of Economics should be either a university professor or a university reader with the salary, conditions of appointment, and tenure which we have laid down as proper to university teachers.

3. The School of Economics should become a constituent college in the Faculty of Economics, subject to its compliance with the conditions as to university management we lay down. But immediate additional funds are needed for salaries and for library maintenance.

4. The main teaching of the University in the Faculty of Economics should be centralised at the School of Economics.

5. The University Department of Ethnology should be placed for the present in the School of Economics.

6. The Foxwell Library of Economic Literature should be housed in the School of Economics.

The Faculty of Medicine comes next in order in the report. It is considered at greater length than the other faculties, and for the moment it will be more convenient to leave it aside and pass to the Faculty of Laws. With regard to this, it is pointed out that there ought to be a Faculty of Laws, but that at present there is no body of teachers in London to whom the title, status, and salary of university professors or readers in law have been assigned, or who have been recommended by a board of advisors for those titles. Absence of endowment is chiefly responsible for this, but the Commissioners consider that it would not be in the interests of the University or of the present teachers of law to confer the powers and privileges proper to a university faculty upon the present faculty. The teaching of law is not conducted in any separate institution, but there is a proposal to concentrate it at King's College, and when money is forthcoming for the appointment of professors and readers, whichever college provides the teaching will become a constituent college in the Faculty of Laws. The Commissioners point out that the whole body of law, including the law of England as it stands to-day, is capable of scientific treatment, and is a department of learning with which a university ought to deal. The most scientific treatment of it which a university can provide is the best foundation for professional work. Regarding the university as the real seat of learning, they hold that it is as the faculty of a university that the scientific study of law should be carried on in its relation to other departments of learning. The Faculty of Laws should be a superior faculty, they say, and it should be necessary to take a degree in arts or science before proceeding to a degree in law. But the degree in law has long been a first degree in London, and a faculty cannot be established at once, and the time for a change should therefore be left to the discretion of the University. The Faculties of Theology and Music are dealt with more briefly. The Commissioners recommend that the former faculty should be a superior one, and find that the constitution and purposes of the existing theological colleges are unsuitable for constituent colleges of the University. The Faculty of Music of the kind that has hitherto existed in the University of London the Commissioners consider useless. The granting of external degrees might be continued, and the professor should belong to the Faculty of Arts.

(To be continued.)

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—At a meeting this evening (Friday, May 2nd) in the society's rooms, West London Hospital, at 8.30 P.M., a paper will be read by Professor Frederick Hobday, F.R.C.V.S., on Observations upon Some of the Diseases Communicable from Animals to Man.

THE LANCET.

LONDON SATURDAY, MAY 3, 1913

The Duration of Protection Afforded by Vaccination, and the Importance of Dosage.

DURING the small pox epidemics of last century, and particularly in the pandemic of 1871, there were few questions with which medical men were so familiar or to which so much attention was given as the evidence of the duration of the protective effect of vaccination against small pox It was customary to measure this by different criteria the proportion of fatal to total cases at different ages, the proportion of mild or modified cases to total cases and the relative incidence of small pox on the vaccinated and unvaccinated at different periods of life The conclusions which became generally accepted as a result of these observations still govern practice and are taught at the present day, but it is natural to inquire, during a period of long immunity from small pox epidemics, and at a time when comparatively few men obtain their knowledge of the disease from direct observation whether it is now necessary to revise them in consequence of changes in the type of small pox, or of differences between modern and ancient vaccines and methods of vaccination or on account of other causes which may have been at work Dr W HANNA, assistant medical officer of health for the Port of Liverpool, has taken advantage of the systematic keeping of records in the Liverpool small pox hospitals during the 1902-03 epidemic and subsequently, to make a critical examination of the facts in over 1100 small pox cases in their bearing on the problems to which we have referred, and by so doing he has rendered a very valuable service to medicine and public health [1] The results as a whole, accord very closely with those of the earlier periods As regards case mortality at all ages that of the natural disease—i e, in the unvaccinated, which ranges from approximately 25 to 40 per cent —was reduced by the power of vaccination to about 3 per cent in those that have been well vaccinated In the unvaccinated Dr HANNA finds that it is persons at the extremes of life, mainly children under 10 years and old people who suffer most, in the previously vaccinated he has no case at all in children under 3 years of age and no deaths under 20 years but as age advances, the protective power of vaccination against death from small pox and its power of modifying the severity of the disease are gradually lost The fact that the duration of protection conferred by vaccination against attack by small pox is much shorter than the duration of its power of modifying the disease is also well illustrated by the Liverpool figures, the influence of the latter can be traced far on into late life Vaccination may "take" and pass through a typical course when performed at any time between exposure to small pox infection and the appearance of the rash if small pox develops During the first three days the degree of the protection thus conferred against attack is very high Although Dr HANNA does not find it absolute in those who are vaccinated for the first time during these early days of incubation yet the course of the disease when it occurred in such cases was extremely mild He is inclined to conclude that the modifying power of vaccination will be shown even when the case has not been vaccinated until the date of onset of small pox and that modification may take place as a result of vaccination performed after the disease has developed The data for the last conclusion are small, but the conclusion itself accords with modern knowledge of vaccines generally and the question is well worth further study at small pox hospitals

Dr HANNA S observations on the significance of the area of vaccination scars are of special interest There can be no doubt of the fact that the Liverpool experience bears out the statement that the scar area of vaccination has an important relation to the severity of small pox, the larger the area the milder the character of the disease It is of course, important to take account of the natural growth of vaccination scars, which get larger as age advances until the 20 30 year age period is reached and then gradually become smaller in all probability owing to atrophy of the scar tissue Analysis of cases in terms of number and area of scars should therefore be particularly directed to age groupings, and it is in this way that the evidence of the great importance of securing a sufficient dosage of vaccine in the performance of vaccination is best brought out Dr HANNA S little book, which contains some excellent illustrations of small pox cases and of concurrent variola and vaccinia will perhaps be in special demand by medical officers of health and public vaccinators, but it may cordially be recommended to a wider public

◆

Death Certification, Especially in Respect of Lunatics.

AT a recent meeting of the Medico Psychological Association a paper was read by Dr SIDNEY COUPLAND, Commissioner in Lunacy, upon the subject of the certification of deaths and their official registration A highly interesting discussion followed proving that the apology with which Dr COUPLAND prefaced his communication was quite unnecessary His justification for introducing for the consideration of the Association a subject having little obvious relation to the problems usually discussed at their meetings was complete The changes in the regulations for the registration of deaths which have been introduced recently with the object of securing greater uniformity in tabulation, and consequently greater accuracy in national statistical results, are fraught with real importance to all branches of medicine, while the duty of attesting the cause of death of a patient which is imperative on every practitioner of medicine, is especially so in the case of the medical officers of lunatic asylums, who, moreover, possess ample opportunities for obtaining precise information For in these institutions the cause of death is verified by necropsy in at least three-fourths of the cases that terminate fatally.

---

[1] Studies in Small pox and Vaccination By W Hanna M A M D D.P H Bristol John Wright and Sons Limited 1913 Price 7s 6d

Commenting on the recent issue by the Registrar-General of an "Official Manual of Causes of Death," respecting which a notice appeared in our columns at the time,[1] Dr. COUPLAND reviewed the history of death registration in this country from its establishment in 1838 down to the present date. It is familiar knowledge that the classification of diseases, with a view to the accurate registration of causes of death, originated with Dr. WILLIAM FARR, the distinguished founder of vital statistics. The classification which, after much patient labour and investigation, was adopted by him formed the basis of the first edition of the nomenclature of diseases issued in 1869 by the Royal College of Physicians of London, which body since that time have rendered great service to science by the decennial revision and publication of their nomenclature. At the request of the Geneva Statistical Congress in 1856 Dr. FARR, in coöperation with Dr. MARC D'ESPINE, prepared a report on the nomenclature and classification of disease, with the object of establishing an international system—a scheme which is now about to be realised. Several modifications of the original classification were adopted from time to time by Dr. FARR; and his successors, Dr. WILLIAM OGLE and Dr. JOHN TATHAM, have revised the nomenclature for use in the General Register Office in order to bring it into line with the decennial revisions of the Royal College of Physicians of London. In the Registrar-General's last annual report it was announced that the list of death-causes authorised by the International Commission of Paris in 1909 will be adopted in all future publications by Somerset House. This modification of the official nosology will bring English mortality records into line with those of other European countries; and as the vital statistics of England and Wales will henceforth be published for the same districts as those into which the country has been divided for purposes of sanitary administration, there is at the present a double effort towards harmony.

The Lunacy Commissioners, recognising the distinct expediency of adopting for institutional use a synopsis of death-causes in accordance with the tables in the national returns, have authorised a revised schedule for use in the reports of asylum medical officers, and this schedule came in for some criticism at the hands of the members of the Medico-Psychological Association. In certifying the cause of death probably the chief difficulty encountered is the ambiguity which has from the first attached to the expressions "primary" and "secondary" in relation to that event. And, for the reason that in the statutory records one cause alone can be tabulated, the difficulty referred to is obviously critical. This is the most often discussed point in our system of death certification. A code of rules has long been in use at the General Register Office to determine which of the causes of death assigned in the medical certificate could reasonably be regarded as the most important factor. In 1903 a similar code was compiled by an International Commission. For the first time, both these sets of rules are now published in the official manual, the study of which will be found instructive and helpful in death certification. From the manual we learn that there is a growing tendency among practitioners to give the more correct rendering of the term "primary" as principal, rather than as first in point of time; and to this practice Dr. COUPLAND advised his hearers to conform. As an aid to that end the certifying practitioner has now before him an authoritative definition of the terms in question. The wording of this definition has recently been settled after consultation with the Royal College of Physicians of London. It runs as follows: "By 'primary cause of death' is meant (in the case of death from disease) the disease present at the time of death, which initiated the train of events leading thereto, and not a mere secondary, contributory, or immediate cause, or a terminal condition or mode of death." Respecting the expression "secondary," inasmuch as differences of opinion are inevitable as to the precise meaning of the term "primary" in estimating the relative importance of one or other morbid states in causing death, it becomes necessary to keep in view those conditions which are noted as "secondary," since they find no place in statistics dealing with one cause only. And we may here record with satisfaction that the Registrar-General intends to publish from time to time subsidiary tables to include both groups, where the secondary cause is sufficiently important to warrant its tabulation.

In the more limited statistics of lunacy it is proposed in the future to ask for a record, in a separate column, of the total number of instances in which a disease is regarded as secondary. In that way it is hoped that a truer conception than the present may be arrived at concerning the relative frequency of each morbid condition sharing in the fatal issue. As illustrative of lunacy experience Dr. COUPLAND instanced, among others, the case of general paralysis of the insane, which accounts for so large a proportion of the deaths in asylums. It is noteworthy that although the return of this disease as the primary cause may generally be justified, in some cases it does clearly rank as secondary, when complicated, for example, by dysentery or phthisis. The same applies to epilepsy and disease of the brain and cord, serving to emphasise the importance of tabulating secondary as well as primary causes, if we wish for accurate knowledge of the prevalence of such affections. Respecting some other diseases which are exceptionally prevalent among the insane, as compared with the general population, the results of clinical experiences are recorded. Among these, next in importance to general paralysis, as contributory to an asylum death-rate, comes pulmonary tuberculosis, which accounts for 14 per cent. of the total asylum mortality as contrasted with 10 per cent. in the mortality of the rest of the community. On the other hand, cancer comes low in the list of fatal diseases among the insane. In the year 1910 the proportion of deaths from this cause among persons at ages above 25 years was 33 per 1000 in asylums as against 114 per 1000 among the rest of the community. But when the incidence is compared, of tuberculous phthisis and cancer, among equal numbers living respectively inside and outside asylums, we find, in the one case, a still greater disparity, and in the other an equally striking approximation in the respective rates.

---

[1] THE LANCET, Feb. 24th, 1912, p. 528.

Thus, in each 10,000 living the asylum deaths from phthisis were 127, that of persons outside asylums only 13 But in regard to cancer, the like ratio for the former was 29, for the latter 20, which would seem to show that, in spite of its relative infrequency as a cause of asylum mortality, the incidence of cancer is not really below the rate in the general community Statistics are forthcoming from which it would appear that the prevalence of cancer is not favoured by agencies similar to those which favour the spread of tuberculosis, but the conclusions based as they are on statistical comparisons of communities numerically unequal, must be guarded and undogmatic Clearly such figures point the direction for future inquiry, and cannot be accepted as expressions of ultimate truth

Annotations.

"Ne quid nimis

THE DECLINING BIRTH-RATE IN GERMANY

The declining German birth rate is a subject which has already for some time been engaging the active attention of the authorities, and it is generally recognised that the question has become one of national importance In two Prussian provinces the authorities have gone so far as to forbid the usual publication in the daily papers of the names of the recently married and of those about to marry, in order to prevent the contracting parties being flooded with prospectuses and price-lists of anti-conceptional appliances Already the fall in the birth rate is beginning to be noticeable in the decreasing number of children entering the German elementary schools this year The limitation of families according to recent observations, is by no means confined to the so called better classes, it is also being practised more and more by the skilled workmen The total statistics for the whole of the German Empire for 1912 are not yet available, but from the figures already published for 42 of the large towns it is abundantly evident that in spite of the improvement in the death rate the birth rate continues to decline steadily Compared with 1911, the decrease in the number of births during 1912 was particularly marked in Frankfort o/M, Neukolln, Schoneberg, and Wiesbaden These are all prosperous towns, indeed, they are termed the "towns of the people with independent means owing to the large number of well to-do persons retired from business or duty who select these for a residence Two are suburbs of Berlin, and one, Schoneberg, holds the record as regards decrease in the birth rate This decline is even more striking when the figures of ten years ago are compared with those for the past year An illustration may be given for a few of the larger cities —

	1902.		1912	
	Total births	Per 1000	Total births	Per 1000
Munich	17 861	35 1	13 458	21 9
Leipzig	14 922	31·5	13 400	22 1
Dresden ..	12 712	31 5	11 301	20·3
Cologne	14 621	37 8	14 232	26·7
Breslau	14 424	33 4	13 961	26 4
Nurenberg	10 373	33 7	9 025	25 5
Hanover	6 574	27·0	6 371	20·3
Mannheim	6 211	42 6	5 823	23·7
Strassburg	4 635	30 0	3 923	24 4
Schöneberg ..	2,825	26 5	2 430	13 7

In the last named the birth rate in ten years has thus dropped by very nearly one half The above figures refer only to the number of infants born alive leaving the number of stillborn entirely out of consideration On the other hand, the decrease in the birth rate is really greater than apparent from the above figures when it is borne in mind that all these towns have had within the same period to record a very great increase in population, due to the ever-increasing influx from the country The natural increase in population in Germany—i e, the surplus of births over deaths—at present amounts to about half a million annually.

THE TITLE OF "DOCTOR."

Until the end of last year a by law of the Royal College of Physicians of London ran thus 'No Fellow, Member, Extra-Licentiate, or Licentiate of the College shall *assume the title of doctor or* append to his name the title of doctor of medicine, or the letters of M D or any other letters indicating that he is a graduate of a university, unless he has obtained a degree entitling him to do so By a resolution of the College passed on Dec 12th of last year the words in italics have now been omitted It is doubtful whether the full bearing of this change has been appreciated by the Licentiates Hitherto they have been under a certain disadvantage—namely, that although they had passed a good qualifying examination yet if they did not also possess a university degree entitling them to do so they were forbidden to take the designation of doctor The alteration of the by law removes this disability, and they are now permitted to style themselves Dr —— on doorplates, visiting cards, and so on, if they wish to do so It must be distinctly understood, however, that this is only a courtesy title, or perhaps it might be termed an occupation or professional title, as distinguished from "doctor of medicine' which is an academic title. Nevertheless, we feel sure that the removal of the restriction to assume the title of doctor will be greatly appreciated by many of those directly concerned Previously the distinction between practitioners who did and did not hold university degrees was rather an invidious one, as it tended to the idea that their professional skill and knowledge were similarly unequal, which was by no means necessarily the case, now without fear of any reproach for using a forbidden term the Licentiates of the Royal College of Physicians of London can adopt the professional title which is generally understood by the public to indicate that they are duly qualified practitioners of medicine

THE DIET OF THE GLASGOW LABOURING CLASSES

The interesting report on the food of the labouring classes in Glasgow, which was referred to by our Glasgow correspondent recently, has now been issued by the authority of the corporation of that city The inquiry, it will be remembered, deals with the diets of poor families from the points of view of physiological energy and of cost The collection of the necessary evidence required great tact in dealing with the households concerned, and an infinity of care and exactitude in the preparation of the numerical factors afforded The work was carried out by Miss Dorothy E. Lindsay, B Sc, assisted by a small staff, working under the supervision of Professor D Noel Paton The method of work is the same as that carried out in Edinburgh in 1900, it consists in enumerating each household, and weighing, classifying, and pricing all the food consumed by that household during a given period Sixty houses were selected from the poorest parts of the city, and they are arranged in seven groups according to variations in income, with three additional groups of inebriate parents and exotic racial distinctions (Hebrews and Italians) The articles of diet are arranged under the headings of proteins, fats, and carbohydrates, and their physiological value is stated in calories calculated in the usual way In estimating the relative requirements of men, women, and children in any given household, the standard used was Atwater's tables. By these tables the food consumption of any family is worked out in terms of "one labouring man" unit, women and children being recorded in terms of decimals. The proper average of diet is usually estimated at 3500 calories per man, but the total average found in this investigation was only 3163 calories, and even with the higher ranges of income the energy value of the food did not reach higher than 3467, and in some abnormal cases it was as low as 2700. The cost per man per day averaged 7·07*d.*, and in some instances it was as low as 6*d.* The principal foodstuffs were found to be bread, potatoes, beef, milk, sugar, and vegetables, and of the proteins consumed about two-thirds are vegetable protein. Hardly any oatmeal or peas or beans is used now in Glasgow among the poorer classes, and cheese is consumed in very small amounts. The remedies suggested by the investigators will unfortunately not commend themselves to the palates of the persons concerned. Bad cooking, bad marketing, and a bad choice of food are responsible rather than restricted means. The only practical improvement would be a return to a simple diet including much oatmeal, and it might be suggested more cheese in place of the expensive protein-rich animal foods, meat, fish, and eggs, which when procured are of inferior quality.

THE SPREAD OF PELLAGRA.

MUCH has been written in recent years concerning pellagra, more especially in the United States, where the disease seems to be spreading in certain localities, causing considerable uneasiness, not to say alarm, in the minds of many people. Numerous inquiries have been made with the view of definitely proving what is the origin of the malady, but, so far, without any marked success. A very instructive contribution on the subject has lately been published in our American contemporary *Public Health Reports*, in the issues of March 7th and 14th, by Passed Assistant Surgeon R. M. Grimm, of the Public Health Service, who undertook an investigation during the summers of 1911 and 1912 into the circumstances associated with pellagra cases in an area comprising portions of three States, Kentucky, South Carolina, and Georgia, where the disease was reported to be spreading. A large section of the population in this area are negroes. In the course of his inquiries Dr. Grimm conferred with 200 medical men practising in this region, and from them obtained notes of 1426 cases, 323 of which he personally interviewed. In the investigation which followed attention was paid to the general character of the classes of people attacked by pellagra, to occupation and economic circumstances, to the situation and sanitary condition of the patients' homes, to their food- and water-supplies, as also to the question of biting insects and their possible relation to the spread of the malady. It appears that the majority of the sufferers who were visited by Dr. Grimm belonged to families of slender means, whose general environment and conditions of life were of a very low standard. Most of them seemed to be living a hand-to-mouth existence, depending for their support on what they earned day by day. Most of the people affected belonged to the families of cotton-mill workers, miners, and artisans, while only 48 out of the 323 were of the agricultural class. Medical opinion was to the effect that these people were not receiving the proper quantity or quality of the food they needed, and in many families the dietary even when of proper quality received very hasty and incomplete culinary preparation. These people largely lived on articles of food bought from day to day at the small local grocery stores, where most of the stock consisted of articles which had undergone some process for their preservation, such as canning or desiccation. No constant difference could be discovered in the dietaries of the pellagrous and the non-pellagrous membe of the same families. "Hominy and meal" seemed to b the form of "corn" most in use. As regards biting insect the great majority of the houses visited afforded evidenc of infestation by these, including the common bed-bug Mosquitoes are present in the area under investigation and the ordinary house-fly is found practically in ever house; they were observed to be especially numerous i any house where a pellagrous patient was confined to bed Some of the local granaries were seen to be heavil infested by weevils and moths. In a number of place the simulium fly could be detected, sometimes in clos association with pellagra cases. There are many runnin streams in the affected area, and none of the homes o the pellagrins seemed to be very far from running water It is important to mention that besides the cases reporte to Dr. Grimm he saw a number of other instance among the resident population presenting symptoms of suspicious sort suggestive of pellagra. They were, in fact on the borderline, possibly in the earlier stages of th disease, but to say that they were actually cases o pellagra was not easy. There are certain conditions whic seemingly predispose to pellagra through a lowering of th body's powers of resistance, such as hard work, worry grief, or some previous illness. Enlarged thyroid wa seen in some female pellagrins, but it was not constant. It is noteworthy that more cases of pellagra were found among the white population than among the negroes, and that more females of each race were attacked than males, and for this curious circumstance no satisfactory explanation is as yet forthcoming. When blacks suffer from pellagra their case mortality is higher than that of the whites, as also is the insanity incidence rate, males having a higher rate in this respect than females. Dr. Grimm, in conclusion, admits that the evidence he has collected does not afford proof of a relationship between the character of the food-supply and pellagra, but he insists that no investigation into the etiology of this disease can ignore the nature of the dietary of the persons attacked. On the other hand, the possibility of some insect playing a part in the dissemination of the disease does not seem to be inconsistent with the facts collected. Further investigations on a large scale are suggested by Dr. Grimm, and no one will deny the need for such inquiries, so that the etiology of this puzzling disease may be elucidated and that measures of prevention may be formulated without unnecessary delay.

OBSERVATION IN THE STREET.

A PRETTY argument might be waged upon the merits of a town walk and a country one as stimulants to observation. We can imagine the town advocate declaring that if he walked a country road in the winter there was really nothing for him to notice but the bareness of the hedges and the trees. Even in the kindlier seasons he can find comparatively little to see or hear. The old truism is illustrated that we only see what we look for, and the townsman in the country does not know what to look for nor where to look for it. The countryman in town is in another case. So much is thrust upon his observation that he is overwhelmed, and he also sees nothing, but for an opposite reason. His wits, moreover, are entirely occupied with avoiding a catastrophe from motor-'buses and taxicabs when he crosses a road or from the innumerable pedestrians when he keeps to the pavement. Yet to the initiated safe progress becomes an unconscious habit, and the eyes and brain are at liberty to observe. What scope and variety of objects and of persons a London walk affords is too little appreciated by most who pass along the streets. What do most of these people look at as they go? It is an interesting question, and the regrettable fact is that if a hundred persons who walked down Regent street were asked at Piccadilly what they had been looking at since they left Oxford Circus, probably about 90 would reply, "Nothing in particular", if they were truthful that is to say, which is hardly to be expected in so large a proportion The ten observant folk would, we imagine, all be women who had been looking in the shop windows They had walked with a definite object in view They knew, more or less, what they were looking for, and they certainly knew where to look for it Consequently their walk was a practice in observation, whereas for the other 90 it was a lost opportunity There is great pleasure, no doubt, in merely walking along and letting the eyes and thoughts wander carelessly and unreflectingly Such an excursion provides, at any rate, gentle exercise for the body and almost complete rest for the mind But to him who walks and looks for something definite the street affords a finer recreation If he looks for character, for types of nationality for distinctive evidences of profession, for symptoms of disease, even for traits of fashion, what an enlightenment is his stroll Instead of a vague and slightly annoying rabble that a little interferes with his progress the crowd of passers by becomes a number of units each full of interest and meriting the quickest and closest observation The whole value of the street is altered Instead of being "a boy among the pebbles' our observer becomes a geologist on the beach He has something to look for and an endless field of observation in which to look for it Happy is he whose training has taught him to observe, and there is no item of a medical education that more deserves our gratitude than this

BILATERAL CEREBRAL ABSCESS INVOLVING THE MOTOR AREAS

FEW cases of symmetrical abscesses of the brain have been recorded In the *St Paul Medical Journal* for April Dr W A Dennis has *reported a case* in which each motor area was involved, producing practically complete double hemiplegia A youth, aged 18 years was transferred from the medical to the surgical service of the University Hospital on Feb 2nd, 1912 with the diagnosis of localised left pyo pneumothorax communicating with a bronchus On the 5th, 3 in of the eighth rib were resected, several ounces of thick foul pus were evacuated, and the cavity, which was found to involve the lung substance, was drained The temperature, which had been 102°–103° F in the evening quickly dropped to normal, and the offensive expectoration, which had been profuse, diminished The patient got up and was greatly improved, though the discharge from the wound remained profuse On the 24th he had an attack of aphasia characterised by a fixed stare and the repetition of the words ' water' and "what ' He seemed unable to form a sentence On the next morning he felt well, but in the *afternoon a similar attack, lasting about a minute,* occurred On the 27th there was another attack with rigidity of the right hand Cerebral abscess was then diagnosed On the following day another attack of aphasia occurred, and he appeared to be paralysed on the right side But after this he talked intelligently for a few minutes and ate his dinner Soon he became aphasic, the fingers of the right hand twitched, and the arm was held stiff Half an hour later there was a general convulsion and the whole body twitched about for four minutes, during which he was unconscious After three hours he was much better and fully conscious On the 29th all he complained of was headache on the right side of the head He was bright, talked normally, and had no paralysis A neurologist who saw him in consultation diagnosed abscess beginning to form in the left temporal lobe The patient did not seem in a favourable condition for operation, which was postponed for a few days Then other symptoms developed On March 4th the left hand felt numb On the 5th the left arm was jerked about for five minutes, and on the next day it was paralysed Later in the day there was a general convulsion more marked on the right side and paralysis of the whole body followed Still later in the day he could move the left arm and leg, and again still later the arm became paralysed Two days afterwards he could use it again He often complained of headache, and vomiting occurred There were double optic neuritis and incontinence of urine The temperature was subnormal much of the time, and the pulse varied from 60 to 90 On the 16th an osteoplastic flap was made over the left motor area, and at the depth of about 2 cm an abscess containing 1½ ounces of thick offensive pus was found and drained The abscess lay beneath the ascending frontal convolution and extended downward and backward for about 3 cm Next day the temperature was normal and the pulse 86 He could move both legs and the right hand, but the left hand was paralysed He could not speak, but appeared to understand what was said to him On the 19th the pulse suddenly rose to 160, and from this time until death, which took place on the 30th, his condition was critical The right arm was often used but never the left The right pupil was dilated An abscess in the right motor area was suspected and the question of a second operation was considered, but was not performed on account of the bad condition of the patient and the opinion of the neurologist that this was due to extension of pus towards the base of the brain At the necropsy the drained abscess was found almost obliterated In the corresponding area on the right side was an abscess rather larger than the one on the left side In the anterior pole of the left frontal lobe was a third small abscess Each abscess was distinctly limited by a capsule and there were no signs of involvement of the meninges or ventricles As in most cases of multiple abscess of the brain, the lesions in this case were embolic from a primary focus in the chest

A RECENT ANALYSIS OF ASPARAGUS

THE popularity of asparagus makes a fresh analysis of it interesting When we remember that asparagus belongs to the same family of plants—the liliaceæ—as do the garlic, leek, and onion we may expect to find some constituents in common Sulphur combined in the form of an oil is, perhaps, the most prominent of these but in asparagus it is not so obvious to the taste and smell as it is in the raw onion Curiously enough, however, when the tender shoots of asparagus are left in water for a few days we find that the smell of onions quickly develops and after a time becomes very marked Again, if asparagus is extracted with ether an oil is obtained which has a faint smell *of the raw shoot This oil, on analysis, proves to contain* sulphur It is probably this sulphur constituent which gives the well known peculiar odour to the kidney excretion after a diet of asparagus, and not the other principle peculiar to asparagus, asparagin There is reason for believing, however, that asparagin has decidedly diuretic properties According to our analysis it occurs in the tender shoots to the extent of about 0 5 per cent As to the actual nutritive value of asparagus, this must be placed low, especially in view of the fact that what nutritives exist in the plant are rapidly extracted by boiling and even by cold water Approximately only a tenth part of the raw asparagus shoot is solid matter, and as much as 70 per cent of this is soluble in cold water, while quite 80 per cent is soluble in boiling water It follows that in the process of cooking a very considerable

The artificially heated theatre here should not, we imagine, be much cooler than the artificially cooled theatre in a tropical country. Ether is freely used by evaporating methods in European and American operating theatres, and probably could be equally employed in many places where it is at present regarded as taboo. We are strengthened in this opinion by an article in the *Bulletin of the Manila Medical Society* (February, 1913). This is from the pen of the anæsthetist to the Philippine General Hospital, who writes with an experience of 19 months in Manila, during which time there were some 1600 cases. The writer remarks that it was surprising to find ether being very satisfactorily administered in Manila. She (for the writer is a woman) went from Chicago, where opinion as to the use of ether in the tropics is much the same as that to which we have referred above. Guided by what she saw, she instituted the giving of ether by the drop method, to which she was accustomed at home. This she finds quite satisfactory with the proviso that considerably—in her opinion from 15 to 20 per cent.—more ether is required per patient than in cooler climes. The only real difficulty, as might be anticipated, is in the storing of the ether. The tin cans so commonly employed in America were not sufficiently air-tight and much evaporation of ether took place from them. The ideal vessel she describes as a glass container. The boiling point of ether is about 95° F. and it should not be difficult in many tropical places to store ether where this temperature would not be reached, nor to procure it in bottles that would allow no leakage if so stored.

A NEW ANTITYPHOID VACCINE.

OF the vaccines which have hitherto been used as prophylactics against typhoid fever, the one prepared by Pfeiffer and Kolle and employed in Germany consists in agar cultures of the bacilli killed by heat, while Wright's preparation is made from bouillon cultures sterilised, according to the original method, by heating to 60° C., or in Harrison's modification of the procedure to a temperature of 53° C. The latter thus contains, in all probability, soluble products of the bacteria formed in the fluid culture medium, and these may be of some importance in the production of immunity, since Levy and Fornet found that filtrates of typhoid cultures had not only an aggressive but also a protective action. A recent modification in the mode of preparing vaccine has been carried out by Levy and Bruch,[1] who make use of the power possessed by some neutral salts to kill bacteria by the altered osmotic conditions brought about by the addition of suitable quantities to fluid media, the bodies of the organisms being broken up and disintegrated. Levy and Bruch have used galactose for this purpose, as this sugar can be sterilised by heat without undergoing alteration, adding 1 part of galactose to 3 of a broth culture of typhoid bacilli, evaporating the solution to syrup, and finally drying *in vacuo*. The resulting white powder is further ground up; for use it is dissolved in distilled water. Comparative experiments on guinea-pigs with Wright's preparation, with a similar vaccine in which the bacilli were killed with carbolic acid, and with the dry vaccine prepared as above described, showed this last to have superior immunising power, while its injection gave rise to little reaction. Its toxicity was greater than that of the other preparations, possibly showing that the active substances were less altered when obtained by this means than by heat or antiseptics. This toxicity diminished with keeping, while the immunising power of the powder remained intact. The writers believe that a dry vaccine of this nature will be of considerable advantage for foreign and colonial use, as it keeps well in spite of high temperatures. No trial of the new vaccine on human subjects is recorded.

INDUSTRIAL DUST EXPLOSIONS.

AN interesting report has been issued from the Home Office this week on the inflammability and capacity for transmitting explosions of carbonaceous dusts liable to be generated on premises under the control of the Factory and Workshop Acts. According to the author of the report, Dr. R. U. Wheeler, the chemist attached to the Explosions in Coal Mines Committee, the dusts examined may be divided into three classes—viz.: (1) those which ignite and propagate flame readily, the source of heat required for ignition being comparatively small, e.g., a lighted match; (2) those which are readily ignited, but which require a source of heat of large size and temperature, e.g., an electric arc, or the flame of a Bunsen burner; and (3) those which do not appear to be capable of propagating flame under any conditions likely to be present in a factory. The investigation was prompted by two serious dust explosions which occurred in November, 1911, at a provender mill in Glasgow, and at an oil-cake factory in Liverpool. Altogether 66 samples of dust were examined, which were not specially selected, but taken from beams, ledges, or other projections by the factory inspectors in the course of their inspections. In Class I., sugar, dextrine, starch, and cocoa proved to be most dangerous. This class includes also flour, tea, chicory, and cork. In Class II., samples of shoddy, being of a fluffy nature, did not readily form a cloud in air, but they contained a sufficient quantity of fine material to render them dangerous when in bulk. In the same class a sample of shellac contained over 60 per cent. of incombustible matter, but all the same was inflammable. This class included also oil cake, sawdust, horn meal, and mustard. In Class III., some samples were more or less readily inflammable, but showed no signs of being capable of propagating flame. The report is a valuable one, and indicates clearly those manufactures in which dust may easily be a source of danger from its inflammable nature and tendency to explode. We hope the matter will receive that careful consideration which it demands.

THE VENTRICLE-STRIPPING OPERATION IN HORSES.

ABOUT a year ago we referred to the results obtained in "roaring" horses by the ventricle-stripping operation, first made a success by Professor Williams of the Veterinary Faculty of Cornell University, U.S.A., and introduced into this country by Professor Hobday. The operation is now being practised in America, France, Germany, Austria, Italy, Belgium, Holland, and Hungary. In the *Veterinary Journal* for April Professor Hobday, whose own cases now number 695, continues his proposed tracing of the subsequent history of 100 of these for four or five consecutive years—a good average period of useful life for a horse of the hunter class. The first two were operated on in September, 1909, and it is interesting to note that they are still at work to the satisfaction of their respective owners. This list of Professor Hobday's—which refers to the same horses as those in the lists previously published in January, 1911, and April, 1912, respectively—falsifies beyond doubt the pessimistic predictions with which the operation was greeted on its introduction, indicating as it does the permanence of the results attained. Professor Hobday's experience leads him to the opinion that in fully 75 per cent. of cases the operation will convert a roaring galloper from a useless into a useful beast, while for carriage and cart horses the proportion of success goes as high as 90 or even 95 per cent. In one point Professor Hobday has modified his opinion, for whereas he formerly allowed *horses to be tested at the gallop a month after* operation, he is now convinced that this is unwise and that a minimum of two months' rest or, even three, should occur before allowing violent exercise. One possible source of disquietude is dispelled—viz., the fear that the operation may become a "dealer's" operation; for while the horse may gallop noiselessly enough to pass a test for wind, it rarely loses the habit of "grunting" when hard pressed.

---

[1] Arbeiten aus dem Kaiserlichen Gesundheitsamte, 1913, Band xliv., Heft 1, p. 150.

The Right Hon. A. J. Balfour, M.P., will open the new school buildings of Guy's Hospital Medical School on Tuesday afternoon, June 3rd. The opening ceremony will be performed in the Physiological Theatre, after luncheon in the Court Room of the hospital.

MAN'S MENTAL EVOLUTION, PAST AND FUTURE.

By Harry Campbell, M.D., B.S. Lond., F.R.C.P. Lond.,
PHYSICIAN TO THE WEST END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM.

I.

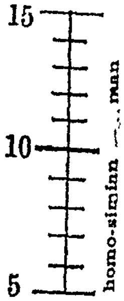
I propose in this essay briefly to consider the factors which have determined man's mental evolution; to seek to discover how far these factors are still in operation, how far they are now being supplemented, or are likely to be supplemented in the future, by others; and to attempt a forecast of his mental destiny. Surely than this no study can be more attractive; none, considering the issues involved, more important.

I shall endeavour to elucidate the laws by which mental evolution takes place, to explain why in some animal species it has advanced further than in others—why, e.g., the primates have reached a higher mental level than the other mammals, and why among the primates man has outstripped all others in the mental race. How came it—and the question must have occurred to many—that of several anthropoid species, one particular species shot ahead in mental development and quadrupled its brain mass, while the gorilla, the ourang, and the chimpanzee have during the long years of man's ascent remained on the same rung of the mental ladder?

If an extra-mundane anatomist, a Martian, let us say, acquainted with the laws of organic evolution, but knowing nothing of this world's animals, were given for examination a man, a giraffe, and a male narwhal, he could not fail to be struck by the large size of the man's brain, the great length of the giraffe's neck, and the enormous development of the upper lateral incisor of the narwhal. He would doubtless argue, *and rightly, that in each case the exaggerated feature* served some special adaptive purpose, and that it must have evolved in accordance with the laws pertaining to biological evolution.

There is, indeed, no doubt that the brain has evolved in accordance with those laws, and inasmuch as it is the organ of mind, we must conclude that mind has evolved on the same lines. Mental evolution has therefore to be studied in the same way as morphological evolution, and the problems for solution are just as susceptible of elucidation in the one case as in the other.

It is convenient to indicate the successive phases of man's evolution from the ape in terms of cranial capacity, according to a plan which I have already suggested.[1] Briefly, it is this: assuming the cranial capacity of the highest anthropoid to be 500 cubic centimetres and of the average European to be 1500 cubic centimetres, we may mount upwards by successive grades of 500 to 1500 cubic centimetres, or (striking out the noughts) from 5 to 15 (see Figure); and if, further, we suppose the rank of homo to have been reached at the tenth grade, the pre-human between the fifth and the tenth grade may conveniently be designated the homo-simian. We can thus speak of a sixth, seventh, eighth, and ninth homo-simian, and of a tenth, eleventh, twelfth, thirteenth, fourteenth, and fifteenth homo or man. On this plan I assume, it will be observed, that the anthropoid emerged by imperceptible degrees through the homo-simians into the human, that he, so to speak, gradually clambered up the ladder by grasping it at the sides, rather than mounted upwards by a series of leaps from rung to rung.



It is difficult to forbear raising here the question whether we are to regard the evolving human as having passed through one species or more than one in his mental ascent. Are we, e.g., to regard the attainment of each successive rung as equivalent to the origin of a new species? or are we to suppose that only one species—the homo-simian—separated the ape from man? These are questions I must leave the zoologist to answer.

At the fifth stage man's anthropoid ancestor abandoned an arboreal for a terrestrial life, being led to this, I suggest, in the search of food, and especially of animal food, which from this time onward right up to the period of fixed agriculture he diligently pursued. At first he was able to secure little more than vermin: the homo-simian was essentially a *vermin-hunting period.* Later he came to hunt game. We may assume that by the tenth grade (representing a primitive type of man, capable of rudimentary language) he had already learnt to stalk, and possibly even to trap, the larger game; and thus was initiated what may be termed the *genuine hunting period.*

Our Social Hierarchy a Mental Hierarchy.

Among primitive tribes the mental level is much the same throughout the whole tribe. While there is always a tendency for some amount of sorting into mental grades—a man of commanding ability, e.g., is not likely to occupy a subordinate position in the tribe—there is no well-developed mental hierarchy. On the other hand, in civilised nations such as our own there has for many generations been taking place an automatic sorting of the population into grades. These constitute not merely a social but a mental hierarchy—one, namely, in which innate mental endowment increases from below upwards. This results from the fact that each social class, except the lowest, is continually being recruited from the best mental types from lower down, notably from the grade immediately below it, while there is a tendency for the inferior types in each class to filter downwards. The result is that among civilised peoples the social grades may be roughly classified as follows: (1) the aristocracy, or hereditary leisured class; (2) the upper middle class (professional men, merchants, &c.); (3) the lower middle class (small tradesmen, clerks, &c.); (4) the upper working class (skilled workmen); (5) the lower working class (unskilled workmen); and (6) the vagrant and unemployable class (with which may be grouped criminals and the worst decadents).

The mental hierarchy which these classes represent is one not only of intellect but of character. Man needs not only brains but grit in order to succeed in life—honesty, sobriety, industry, self-discipline, backed up by a spirit of emulation, and, above all, by will-power. Indeed, if well equipped in these moral respects a man with no more than average intellectual ability may raise himself well above his fellows; but success can be confidently predicted if character is backed by ability: those possessed of both brains and grit are bound to mount upwards. It follows that the members of each social class are, on the average, more richly endowed in both these respects than those of the class immediately below. I refer, of course, to congenital endowment.[2]

In the establishment of this mental hierarchy the woman has played her part as well as the man. Leaving out of consideration the influence of beauty—for it does not concern us here—the possession of wealth has been, and is, the main qualification for the woman's social ascent. Thus a large number of rich heiresses are drafted from the upper middle to the aristocratic class, and this is to the mental advantage of the latter, since middle class heiresses, as the children or relatives of men who have acquired wealth, tend to inherit their wealth-getting capacity, which capacity, as we have already hinted, generally implies both brains and character.

---

[1] The Evolution of Man's Diet, The Lancet, Sept. 10th, et seq., 1904.

[2] It may be argued that the rise in the mental level stops short of the aristocratic class, but in estimating the congenital mental endowment of this class it has to be remembered that its members are placed at a great disadvantage by being leisured. With no incentive to struggle on the one hand, and abundance of temptation on the other, their conditions are not calculated to bring out the best that is in them.

It will thus be seen that in the case of a community like our own a process of selection is at work sorting individuals into mental grades. There is a mental struggle for worldly success, and it increases in stringency from the lower working class upwards. A higher mental excellence is needed to secure an average success in the upper middle class, e.g., than in the unskilled working class. But *although ascents and descents from one class to another* are continually taking place, there is, nevertheless, a certain stability in the composition of each class. People generally marry in their own class, and most of those belonging to a particular class come of an ancestry extending back through many generations of that class. Now this marriage between individuals belonging to somewhat the same mental level must tend to maintain their class at the same level. In the unskilled working class, e.g., there is intermarriage of the inferior, and in the upper middle class intermarriage of the superior, types. This must tend to maintain the mental endowment of each of these classes at a certain level, while at the same time the total effect of the arrangement is to increase the output of good brains. The upper middle class, greatly [illegible] cratic, has the best brains [illegible] between its members is [illegible] superior mental types, and this gives greater opportunity for the breeding of like superior types than would result in the case of a community having no psychic hierarchy. Parents of superior mental endowment are more likely than parents of inferior mental endowment to produce a genius. For this reason I should expect a community with a well developed social hierarchy, and in which individualism is allowed full play, to produce a larger proportion of intellectual giants than one in which there is little social differentiation. As a matter of fact, in such a community as our own the men of outstanding ability are mainly derived from the upper middle classes. They practically never come from the unskilled working-class, and, indeed, comparatively rarely from the "working class" at all—a fact all the more remarkable when we consider how greatly the working class outnumbers the upper middle class. This division of the community into mental grades brings into strong relief the fact that all men are *not* equal.[3]

[illegible] mi [illegible] bet [illegible] not be "how does the civilised man compare mentally with the savage"? but rather "how (in the case of such a nation as our own) does the upper middle class man, the skilled mechanic, the unskilled workman, the vagrant, respectively, compare with the savage"?

The vagrant I should place on a lower mental plane than the savage.[4] How far the average unskilled workman is mentally superior to the savage is matter for investigation: it may be doubted whether he stands on a much higher mental level. Sharing as he does all the advantages of traditional knowledge, we are perhaps apt to place him too high in the mental scale. We must never forget that all the great discoveries, all the great advances of civilisation, have been initiated by the chosen few, by men of special powers, while all alike have benefited by these advances. The rank and file of the community have, as it were, been pushed along in the course of civilisation by the select few, and have shared in the advantages which these have won.

Mental Capacity may be Potential or Actual.

In estimating the mental capacity of an individual or of a race, distinction must be drawn between the potential and the actual. Every human being is born with a certain measure of psychic potentiality—capacity capable of being awakened into actuality by suitable stimuli, but in the absence of these, remaining for ever dormant.

Suppose it were possible for a person to grow up in some isolated part of the world wholly cut off from his fellows. In such a case only a small fraction of his mental potentiality would ever become actual. Not only would he be without language, it is even doubtful whether he would, of his own accord, construct the rudest implement. His knowledge, owing nothing to tradition, would be but the accumulation of his own limited personal experiences. His actual (as distinguished from his potential) mental level would be little higher than that of the ape. It is essentially by mixing with his fellows that a man's dormant capacities are awakened. He *observes and copies his human associates*, and by means of language is able to come into intimate mental contact with them, profiting not only by their experiences but by their traditional knowledge. This traditional knowledge, even before man learnt to record his thoughts in writing, was considerable; since he learnt to do so it has undergone an immense, we may almost say an infinite, increase, and its influence in furthering individual mental development is enormous. What would a Shakespeare, a Newton, a Wagner, have done if he had lived and died among primitive savages such as the Australians?

Bearing these facts in mind, we shall be cautious how we estimate the innate mental capacity of a people by their actual mental development, as displayed, e g., by their culture. It is not safe to conclude that because a race, such as the Australian aborigines, is at a low level of culture it is therefore incapable of a higher; or that because it has no number beyond 5 it is wholly devoid of mathematical ability. As a matter of fact, the children of the aboriginal Australians are nearly, if not quite, as quick at figures as European children. And here let me draw attention to the danger of relying too implicitly on the reports of travellers respecting the mental capacity of primitive peoples. Without living a long time among a people and conversing with them in their own language, it is not possible to get any real knowledge of them. I have seen it recorded, e.g., that the Australians do not believe in a God; yet so far is this from the truth that a missionary who had lived for many years with an Australian tribe and had learnt their language tells me that they had no fewer than 80 gods, the names of whom they were able to recite from memory!

We should be equally cautious in our estimate of the capacity of extinct races. Judged by the crude, chipped [illegible] of polishing a stone implement." Yet it is now believed that the brain of Palæolithic man was, in size at least, equal to that of the modern European.

While it is admitted on all hands that Palæolithic man existed for tens of thousands of years, the evidence of the stone implements he has left behind him shows that during the whole of this long period he made very slight progress in culture. This is a striking fact, and the lesson to be learnt from it is that, lacking the necessary stimuli, mental capacity may for long ages remain dormant—unrealised. Granting that man has increased somewhat in mental capacity during the period of civilisation, I think we must conclude that the vast advance he has made in the industries and in knowledge generally has been due mainly to the fact that civilisation has provided conditions which have awakened dormant capacity, has, i.e., provided the required stimuli. If anyone is inclined to doubt this conclusion, let him consider the history of mechanical inventions. During the last few generations the output of inventions has exceeded that of man's entire previous career. This has obviously been due, not to any sudden increase in his inventive faculty, but to certain conditions which have tended to call out that faculty. Had James Watt lived in Palæolithic times, where would he have found the kettle to suggest the motor power of steam?

This question of unrealised mental possibilities is one of supreme interest. While it is certain that our primitive ancestors only realised themselves to a very limited extent, it is equally certain that modern man seldom, if ever, realises himself to the full: few are even given the opportunity of self-realisation, and those who are but rarely take

---

[illegible] ridiculous.

[4] I ought to specify some particular grade of savage, since all savages are not on the same mental plane. The standard I have in my mind is that of the precibicultural Australian.

full advantage of it. The conditions of our civilisation are such that the majority of our social units are held to a narrow routine of activity, which is often uncongenial, if it is not actual drudgery.

Consider, too, how many men and women there are with splendid potentialities which are never realised through their not having been happily mated. The ideal society is one which gives to each of its units the fullest scope for self-realisation. Unfortunately there seems small prospect at present of such an ideal being even approximately attained.

How are we to account for this large fund of dormant mental power, for this apparent redundancy of mental endowment? The explanation probably lies in the fact that intelligent, as distinguished from purely instinctive, action implies educability, and a high order of intelligent action, a correspondingly high educability. While a stereotyped instinct suffices to adapt an organism to a simple stereotyped environment, it is wholly inadequate as an adaptive guide in respect of a complex and continually varying environment—one which is, so to speak, for ever presenting new problems for solution. Such an environment requires a mind which can store up experiences, and which (in the case of a being living under the complex conditions of mankind) can arrive at knowledge by reasoning. All this demands a supreme degree of educability—in other words, a high psychic potentiality.

Biological Evolution.

Biological evolution takes place by the continued selection through successive generations of favourable variations. Natural selection is without question equally essential to evolution, both morphological and mental, whether we suppose it to operate on mutations alone or on these and fluctuations also. Consider the mental evolution of man. It is manifest that there has been a progressive cerebral, and corresponding mental, development in the evolving human in all his stages, from the pre-human ape to the modern man. This has taken place by the sustained selection of those who have varied mentally in an upward direction. We may leave it to the expert to decide whether these favourable mental variations have been of the nature of mutations or fluctuations or both. One thing we may safely conclude, and that is that, considering the infinite complexity of cerebral structure, the evolving man could not have mounted from the ape to the completed man by a few leaps. Anthropological data suggest that it took at least a million years for the anthropoid to develop into homo sapiens, and that this has been effected by the accumulation through natural selection of an infinite number of successive improvements. Whether the selected variations are to be regarded as mutations or fluctuations matters little, so long as it is recognised that without natural selection mental evolution would not have been possible.[5]

In considering the influence of natural selection on mental evolution, it has to be remembered that in the case of the evolving man it has not merely been a struggle against starvation, against other animals, and against the inanimate forces of nature: it has largely been also a *struggle against the special conditions imposed by the evolving man himself*, and, as we shall see, it has been the stringent selection entailed by these conditions which has brought about man's phenomenal mental ascent.

Natural Selection still Stringently Operative on Man.

A common error, and one into which even leading biologists have fallen, is that natural selection has ceased, or all but ceased, to operate on man. We are continually being told that man has "cast off the yoke of natural selection" as though it were some fearful curse, the strangely ignored fact being that it is by the magic ladder of natural selection that he has climbed to his present pinnacle of excellence, and that without it it would be impossible for him to continue his psychic ascent. Thus Arthur Thomson rejoices in man's happy escape "from under the inexorable sway of natural selection," and comments sympathetically upon his revolt against its action, declaring that we can never again assume "the yoke of natural selection which even early man began to wriggle out of, which man has been more and more effectually throwing off as the ages have passed."[6]

Similarly Professor Ray Lankester asserts that man's mental qualities "have to a very large extent, if not entirely, cut him off from the general operation of that process of natural selection and survival of the fittest which up to their appearance had been the law of the living world"; and in another passage he refers to man as "emancipating himself from the destructive methods of natural selection."

It is true that man's revolt against natural selection has led to the survival of many who would otherwise have perished. But in so far as it has preserved inferior types it can hardly receive the commendation of the eugenist. It is, however, equally true that this vaunted revolt is far less effective than appears at first sight, and that over man, as over all living things, natural selection continues to exert its inexorable and, I would add, beneficent sway, and will continue to do so so long as man exists.

More than 20 years ago, in my work "The Causation of Disease," I pointed out that all deaths from other than purely accidental causes occurring before the termination of reproductive life are, biologically speaking, deaths of the unfit, since they result from an inability to cope with the environment (notably with pathogenic micro-organisms). They are thus instances of natural selection. The number of such deaths is, and always will be, great.

But even this does not put the case strongly enough It has to be remembered that every individual who leaves no offspring behind him is racially eliminated, and so far as the not leaving of offspring is due to personal peculiarity—such as sterility, desire among the married not to have children, neglect of children by their parents, indifference to marriage, lack of qualities in the woman which lead her to be sought or accepted in marriage—it implies the elimination of certain types.

In countries like our own, in which option is free, marriage is more potent to modify the race than in countries such as France, in which it is the usual custom for the parents to arrange the mating. Thus with us marriage must for a long time have been exerting a definite influence on type. On the whole, the better looking women have presumably been selected. It is certain that definite mental types have been selected, both in the case of the man and the woman, and that this has had a definite racial effect and is a genuine instance of natural selection. Here is a wide field for study.

The custom, now so rapidly extending, of restricting the number of births is having a definite effect upon race. The curtailment being greater among the upper classes than among the lower, the latter are the more prolific, and thus there is taking place a retrogressive selection of inferior mental types.

Ever since the first institution of tribal life, natural selection has been busily eliminating the morally defective. The extent to which this elimination is taking place at the present time is not adequately realised. How many cannot we all recall of those who have fallen out of the ranks! Drunkenness, debauchery, criminality, are laying their lethal hands upon the moral weaklings, and purging the race of them.

(To be continued.)

GIFT OF RADIUM TO THE MIDDLESEX HOSPITAL.—Prince Alexander of Teck has received from Sir Charles W. Morrison-Bell a donation of £1000 for the purchase of radium for the Cancer Charity of the Middlesex Hospital.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

MEETING OF COMITIA.

A COMITIA was held on April 24th, Sir THOMAS BARLOW, Bart., K.C.V.O., the President, being in the chair.

The following gentlemen having passed the required examination were admitted as Members of the College:—James Leatham Birley, M.B. Oxon., L.R.C.P.; Joseph le Fleming Coy Burrow, M.B. Edin.; Gordon Ley, F.R.C.S., L.R.C.P.; Gustave Jean Philippe Monod, M.D. Paris; Charles Sheard, M.B. Toronto, L.R.C.P.; and Stanley Wyard, M.D. Lond.

Licences to practise physic were granted to 88 gentlemen who had passed the necessary examinations.

The following Members, nominated by the Council, were elected to the Fellowship:—John Oglethorpe Wakelin Barratt, M.D. Lond. (Liverpool); Edward Stainer, M.D. Oxon.; Henry Russell Andrews, M.D. Lond.; Francis Hugo Thiele, M.D. Lond.; William Philip Sutcliffe Branson, M.D. Cantab.; Walter Henry Maxwell Telling, M.D. Lond. (Leeds); Ernest Edward Glynn, M.D. Cantab. (Liverpool); Thomas Grainger Stewart, M.D. Edin.; John Brian Christopherson, M.D. Cantab. (Khartoum, Egypt); Alexander George Gibson, M.D. Oxon. (Oxford); Frederick Samuel Langmead, M.D. Lond.; Henry Roy Dean, M.D. Oxon. (Sheffield); Thomas Lewis, M.D. Lond.; Maurice Alan Cassidy, M.D. Cantab.; Charles Wilberforce Daniels, M.B. Cantab.; and James Mackenzie, M.D. Edin. Nominated by the Council under By-law LXXI. (*b*), and proposed to the College for election to the Fellowship:—Charles James Martin, M.B. Lond., F.R.S.

The following communications were received:—1. From the Secretary of the Royal College of Surgeons of England, reporting proceedings of the Council of the College on April 10th, 1913. 2. From Miss Ellen L. Wilks, dated March 26th, 1913, asking leave to have a carbon print made of the portrait of the late Sir Samuel Wilks, Bart., which he left to the College. Leave was granted. 3. From Mr. D'Arcy Power, F.R.C.S., dated April 3rd, 1913, asking leave, on behalf of the Section of History of Medicine of the Royal Society of Medicine, to photograph certain portraits of Harvey. Leave was granted.

An alteration was made in the regulation appended to By-law CXVII. whereby candidates for the Membership should be allowed three instead of four hours for each of the written parts of the examination.

Dr. S. J. Sharkey was re-elected the representative of the College upon the Senate of the University of London.

A report was received from Dr. A. E. Garrod concerning the Fourth International Congress on Physio-therapeutics recently held in Berlin.

A report was received and adopted from the Committee of Management, dated March [illegible] Blundell's School, Tiverton, [illegible] and Watford Grammar Sch[illegible] in [illegible] the Comitia.

THE SEVENTEENTH INTERNATIONAL CONGRESS OF MEDICINE (1913).

SECTION OF MEDICINE.

THE Medical Section is under the presidency of Sir William Osler, Bart. The secretaries are Dr. John Cowan (Glasgow), Dr. [illegible] (Dublin), Dr. [illegible] cretary), Dr. H. [illegible] meetings of the section will be held at the Royal Society of Medicine, 1, Wimpole-street, W. The work of the section will comprise: (1) discussions; (2) selected papers; (3) a clinical museum; and (4) demonstrations of clinical apparatus, methods, &c.

The following discussions have been arranged:—August 7th: The Clinical Aspects of Hæmolysis. Reporters: Professor G. Banti (Florence) and Professor F. Widal (Paris). 8th: Correlations of the Organs of Internal Secretions and their Disturbances. (Jointly with Section II., Physiology.) Reporters: Professor E. Gley (Paris), Professor Dr. Baron Alex. von Koranyi (Budapest), and Professor Dr. F. Kraus (Berlin). [illegible] Dr. Biedl a[illegible] Dr. Meltze[illegible] have intimated their intention to take part in the discussion. 9th: The Pathology of Heart Failure. Reporters: Professor H. Vaquez (Paris) and Professor Dr. H. F. von Wenckebach (Strasburg). 11th: Diabetes. Reporters: Professor G. Dock (St. Louis, U.S.A.) and Professor Dr. Karl von Noorden (Vienna). 12th: Differentiation of the Diseases included under Chronic Arthritis. Reporters: Professor L. F. Barker (Baltimore, U.S.A.) and Professor Dr. Freidr. von Müller (Munich).

The afternoon sittings will be devoted to the reading and discussion of independent papers. Among many already promised the following may be mentioned.—Treatment of Leukæmia with Benzol (A. von Koranyi). Treatment of Pulmonary Tuberculosis by Artificial Pneumothorax (Ch. Saugman). Insuffisances Pluriglandulaires (H. Claude, Paris). Der Augenblickliche Stand der Diagnosis der Pancreas-Erkrankungen (F. Wohlgemuth, Berlin). Chronic Bacterial Endocarditis, with a series of preparations illustrating the condition from the Pathological Museum, Mount Sinai Hospital, New York (E. Libman). The Recognition of the Status Lymphaticus in Adults (Haven Emerson, New York). Diagnosis and Treatment of Duodenal Ulcer (Max. Einhorn, New York). A Modified Form (?) of Sporadic Typhus, Brill's Disease (Brill, New York).

Demonstrations of clinical cases of special interest will be held in connexion with the morning and afternoon meetings of the section, and a strong committee has been formed to bring together the best available material for this purpose. Facilities will also be given to any member of the section who wishes to demonstrate any new clinical apparatus or clinical method. All applications should be addressed to the acting secretary, Dr. W. Pasteur, 4, Chandos-street, Cavendish-square, W.

The dinner of the Medical Section will be held at the Connaught Rooms, Great Queen-street, W.C., on Friday, August 8th. For information about the dinner members of congress are requested to apply to the secretary of the *dinner committee, Mr. George Bethell, 11, Chandos-street,* Cavendish-square, W.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 96 English and Welsh towns with populations exceeding 50,000 persons at the last Census, and whose aggregate population at the middle of this year is estimated at 17,852,766 persons, 9013 births and 5052 deaths were registered during the week ended Saturday, April 26th. The annual rate of mortality in these towns, which had been 15·6, 15·2, and 15·8 per 1000 in the three preceding weeks, declined to 14·8 per 1000 in the week under notice. During the first four weeks of the current quarter the mean annual death-rate in these towns averaged 15·4, or 0·2 per 1000 below the corresponding rate in London. The death-rates *last week in the several towns ranged from* 5·0 in Tottenham, 5·2 in Southend-on-Sea, 6·6 in Ilford, 7·2 in Leyton, and 8·6 in Wallasey, to 19·4 in Dewsbury, 19·5 in Bootle, 20·3 in Middlesbrough, 21·9 in West Bromwich and in Stockton-on-Tees, 22·3 in Walsall, and 26·2 in St. Helens.

The 5052 deaths from all causes in the 96 towns were 363 *below the number in the previous week, and included* 338 which were referred to the principal epidemic diseases, against 394 and 412 in the two preceding weeks. Of these 338 deaths, 141 resulted from measles, 80 from whooping-cough, 56 from infantile diarrhœal diseases, 37 from diphtheria, 14 from scarlet fever, 9 from enteric fever, and 1 from small-pox. The mean annual death-rate from these diseases last week was equal to 1·0 per 1000, *against* 1·2 in each of the four preceding weeks. The deaths attributed to measles, which had been 215, 213, and 203 in the three preceding weeks, further declined to

141 last week, and caused the highest annual death-rates of 1·6 in Wolverhampton and in St. Helens, 1·7 in Hastings, 2·2 in Walsall, 2·3 in West Bromwich, and 2·6 in Bury. The deaths referred to whooping-cough, which had been 60, 50, and 74 in the three preceding weeks, further rose to 80 last week, and included 26 in London, 9 in Stoke-on-Trent, 4 in Leeds, and 3 each in Birmingham, in Salford, in Gateshead, and in Newcastle-on-Tyne. The fatal cases of diarrhœa and enteritis (among infants under 2 years of age), which had been 53, 63, and 65 in the three preceding weeks, declined to 56 last week; 23 deaths were registered in London and 2 each in Wolverhampton, Leicester, Liverpool, Manchester, Preston, Leeds, and Middlesbrough. The deaths attributed to diphtheria, which had been 35, 36, and 41 in the three preceding weeks, were 37 last week; 6 deaths were recorded in Portsmouth, 4 in London, 4 in Leeds, 3 in Leicester, 2 in Liverpool, 2 in Manchester, and 2 in Bradford. The deaths deaths referred to scarlet fever, which had been 23, 19, and 17 in the three preceding weeks, further fell to 14 last week, of which number 4 occurred in London, 2 in Birmingham, and 2 in Liverpool. The fatal cases of enteric fever, which had been 16, 13, and 12 in the three preceding weeks, further fell to 9 last week, and included 2 in Gateshead. The death from small-pox occurred in Liverpool.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospitals, which had steadily declined from 2112 to 1334 in the 17 preceding weeks, slightly rose to 1339 at the end of last week; 185 new cases were admitted during the week, against 167, 148, and 215 in the three preceding weeks. These hospitals also contained on Saturday last 824 cases of diphtheria, 695 of measles, 293 of whooping-cough, and 36 of enteric fever, but not one of small-pox. The 1285 deaths from all causes in London were 139 fewer than the number in the previous week, and were equal to an annual death-rate of 14·8 per 1000, coinciding with the rate in the aggregate of the 96 towns. The deaths referred to diseases of the respiratory system, which had been 346, 285, and 329 in the three preceding weeks, fell to 245 last week, but were 22 in excess of the number recorded in the corresponding week of last year. The fatal cases of influenza numbered 32, against 45 and 28 in the two preceding weeks.

Of the 5052 deaths from all causes in the 96 towns, 188 resulted from different forms of violence, and 395 were the subject of coroners' inquests. The causes of 38, or 0·8 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in London and in its 14 suburban districts, in Manchester, Leeds, Bristol, Bradford, Hull, Nottingham, and in 57 other smaller towns. Of the 38 uncertified causes of death last week, 7 were registered in Liverpool, 6 in Birmingham, 4 in St. Helens, 3 in Bootle, 3 in Preston, and 2 in South Shields.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns with an aggregate population estimated at 2,259,600 persons at the middle of this year, 1265 births and 768 deaths were registered during the week ended Saturday, April 19th. The annual rate of mortality in these towns, which had been 17·2 in each of the three preceding weeks, rose to 17·7 per 1000 in the week under notice. During the 13 weeks of last quarter the mean annual death-rate in these Scotch towns averaged 19·1, against a corresponding rate of 16·9 per 1000 in the 96 large English towns. Among the several towns the death-rates during the week ranged from 9·0 in Kilmarnock, 10·8 in Hamilton, and 13·4 in Clydebank, to 21·4 in Ayr, 21·7 in Dundee, and 26·7 in Perth.

The 768 deaths from all causes were 22 in excess of the number in the previous week, and included 72 which were referred to the principal epidemic diseases, against 75 and 83 in the two preceding weeks. Of these 72 deaths, 39 resulted from whooping-cough, 13 from measles, 9 from infantile diarrhœal diseases, 8 from diphtheria, 2 from enteric fever, and 1 from scarlet fever, but not one from small-pox. These 72 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·7 per 1000, against 1·2 in the 96 large English towns. The deaths attributed to whooping-cough, which had been 44, 43, and 44 in the three preceding weeks, declined to 39, and comprised 23 in Glasgow, 8 in Edinburgh, 3 in Leith, 3 in Greenock, and 2 in Motherwell. The deaths referred to measles, which had been 9, 8, and 13 in the three preceding weeks, were again 13 in the week under notice, and included 8 in Glasgow and 3 in Aberdeen. The fatal cases of diarrhœa and enteritis (among infants under 2 years of age), which had declined from 18 to 11 in the four preceding weeks, further fell to 9, of which number 6 were registered in Glasgow. Of the 8 deaths attributed to diphtheria, which showed but slight variation from recent weekly numbers, 2 occurred in Glasgow and 2 in Dundee. The 2 deaths referred to enteric fever and the fatal case of scarlet fever were recorded in Glasgow.

The deaths referred to diseases of the respiratory system, which had steadily declined from 166 to 117 in the four preceding weeks, rose to 153 in the week under review; 31 deaths were attributed to different forms of violence, against 27 and 31 in the two preceding weeks.

In the 16 largest Scotch towns with an aggregate population estimated at 2,259,600 persons at the middle of this year, 1283 births and 751 deaths were registered during the week ended Saturday, April 26th. The annual rate of mortality in these towns, which had been 17·2, 17·2, and 17·7 per 1000 in the three preceding weeks, declined to 17·3 per 1000 in the week under notice. During the first four weeks of the current quarter the mean annual death-rate in these Scotch towns averaged 17·4, against 15·4 per 1000 in the 96 large English towns during the same period. Among the several towns the annual death-rates last week ranged from 7·4 in Perth, 10·8 in Coatbridge and in Hamilton, and 11·0 in Clydebank, to 19·0 in Glasgow, 21·4 in Ayr, and 23·8 in Paisley.

The 751 deaths from all causes were 17 below the number in the previous week, and included 76 which were referred to the principal epidemic diseases, against 83 and 72 in the two preceding weeks. Of these 76 deaths, 34 resulted from whooping-cough, 18 from measles, 16 from infantile diarrhœal diseases, 3 from scarlet fever, 3 from diphtheria, and 2 from enteric fever, but not one from small-pox. These 76 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·8, against 1·0 per 1000 in the 96 large English towns. The deaths attributed to whooping-cough, which had been 43, 44, and 39 in the three preceding weeks, declined to 34 last week, and included 18 in Glasgow, 3 in Edinburgh, 3 in Paisley, 3 in Motherwell, and 2 in Greenock. The deaths referred to measles, which had been 8, 13, and 13 in the three preceding weeks, further rose to 18 last week, and comprised 9 in Aberdeen, 8 in Glasgow, and 1 in Falkirk. The fatal cases of diarrhœa and enteritis (among infants under 2 years of age), which had declined from 18 to 9 in the five preceding weeks, rose to 16 last week, of which number 9 were recorded in Glasgow and 3 in Dundee. Of the 3 deaths attributed to scarlet fever, which showed but slight variation from recent weekly numbers, 2 occurred in Glasgow and 1 in Dundee. The deaths referred to diphtheria, which had been 6, 9, and 8 in the three preceding weeks, declined to 3 last week, and comprised 2 in Glasgow and 1 in Kirkcaldy. The 2 fatal cases of enteric fever were recorded in Glasgow and Dundee respectively.

The deaths referred to diseases of the respiratory system, which had been 127, 117, and 153 in the three preceding weeks, declined to 119 in the week under notice; 34 deaths resulted from various forms of violence, against 31 in each of the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland, with an aggregate population estimated at 1,199,180 persons at the middle of this year, 673 births and 491 deaths were registered during the week ended Saturday, April 26th. The annual rate of mortality in these towns, which had been 23·3, 22·5, and 20·9 per 1000 in the three preceding weeks, rose to 21·3 per 1000 in the week under notice. During the first four weeks of the current quarter the mean annual death-rate in these Irish towns averaged 22·0 per 1000; in the 96 large English towns the corresponding rate did not exceed 15·4, while in the 16 Scotch towns it was equal to 17·4 per 1000. The annual death-rate last week was equal to 24·5 in Dublin (against 14·8 in London and 19·0 in Glasgow), 20·4 in Belfast, 23·8 in Cork, 17·8 in Londonderry, 16·2 in

Limerick, and 17 1 in Waterford, while in the remaining 21 smaller towns the mean death rate did not exceed 18 5 per 1000

The 491 deaths from all causes in the 27 Irish towns were 10 in excess of the number in the previous week, and included 24 which were referred to the principal epidemic diseases, against 37 and 42 in the two preceding weeks Of these 24 deaths, 7 resulted from infantile diarrhœal diseases, 6 from whooping cough, 5 from measles, 3 from scarlet fever, 2 from diphtheria, and one from enteric fever, but not one from small pox These 24 deaths from the principal epidemic diseases were equal to an annual death rate of 1 0 per 1000, which coincided with the rate from these diseases in the 96 large English towns, while the corresponding rate in the 16 Scotch towns last week rose to 1 8 per 1000 The deaths of infants (under 2 years of age) attributed to diarrhœa and enteritis, which had been 11, 10, and 10 in the three preceding weeks, declined to 7 last week, of which number 5 were recorded in Dublin The deaths referred to whooping cough, which had been 5, 3 and 6 in the three preceding weeks, were again 6 last week and comprised 2 each in Dublin, in Belfast, and in Waterford The fatal cases of measles, which had been 14, 14, and 18 in the three preceding weeks, declined to 5 last week, of which number 3 were recorded in Wexford The 3 deaths attributed to scarlet fever, 2 of which occurred *in Belfast* and *1 in Dublin*, were equal to the average in the four preceding weeks The 2 fatal cases of diphtheria were registered in Dublin and Belfast respectively, and that of enteric fever in Kilkenny

The deaths referred to diseases of the respiratory system, which had been 142, 109 and 92 in the three preceding weeks slightly rose to 97 in the week under notice Of the 491 deaths from all causes 151, or 31 per cent, occurred in public institutions, and 11 resulted from different forms of violence The causes of 26, or 5 3 per cent, of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest, in the 96 large English towns the proportion of uncertified causes of death last week was 0 8 per cent

THE SERVICES

ROYAL NAVY MEDICAL SERVICE

THE following appointments have been notified —Fleet Surgeons J L H Phillips to the *Superb* on recommissioning, and S T Reid to the *Goliath*, on becoming parent ship Staff Surgeon R S Osborne to the *Hermes* on commissioning Surgeons *W W D Chilcott to the Superb* on recommissioning, and A S Paterson to the *Goliath*, on becoming parent ship

ROYAL ARMY MEDICAL CORPS

Captain Daniel L Harding to be Major (dated April 26th, 1913)

Colonel R Kirkpatrick, C M G has taken up duty as Assistant Director of Medical Services to the Abbottabad and Sialkot Brigades of the Second (Rawal Pindi) Division

Lieutenant Colonel H J Fletcher has been transferred from Sialkot to Rawal Pindi Cantonment Lieutenant-Colonel S Hickson has been selected for appointment as Honorary Surgeon to His Majesty the King Lieutenant Colonel J Thomson ha [illegible] tour expired Lieutenant C [illegible] aken over charge of the Mili [illegible] nant Colonel G D Hunter D S O, has been placed under orders for service abroad Lieutenant Colonel I R Newland has been appointed Senior Medical Officer of the South Eastern Coast Defences Lieutenant Colonel H M Sloggett has arrived home for duty from Malta Lieutenant-Colonel T B Winter has taken up duty *pro tem* as Officiating Assistant Director of Medical Services to the Colchester District Lieutenant-Colonel G H Barefoot has been appointed to the London District Lieutenant Colonel W C Beevor, C M G has been appointed to hold charge of the King George V Military Hospital at Arbor Hill Dublin

Major N J C Rutherford has arrived home for duty from South Africa Major T E Fielding has been transferred *from the London District to the Southern Command* Major H A Hinge has been appointed in charge of the Surgical Division of the Cambridge Hospital at Aldershot Major H E Staddon has embarked for a tour of duty in India Major D Lawson holds himself in readiness for service abroad Major N Faichnie has been transferred from Delhi Cantonment to Meerut Major B B Burke has arrived home from the Sierra Leone Protectorate Major E W Siberry [illegible] Medical Officer in the London [illegible] Silver has been appointed [illegible] nden, Queenstown Harbour Major J P J Murphy has been transferred from Cape Town to Potchefstroom Major J D Alexander has been appointed to officiate in Command of the Military Hospital at Ranikhet Cantonment Major J B Anderson has taken up duty as Embarkation M [illegible] Fitz G G Fitzgerald [illegible] charge of the Duke of [illegible] Major F Harvey has been appointed to hold charge of the Military Hospital at Leeds Major R S H Fuhr, D S O, has been selected for duty at the Royal Arsenal, Woolwich Major E T Inkson, V C, has been transferred from the Military Hospital at Bangalore to Wellington Cantonment Major I M Mangin *has embarked for service in India* Major E B Steele has been transferred from the London District to Exeter Major W J Taylor has taken over charge of the *Military Hospital at Tower Hill, Sierra Leone* Protectorate Major O J O Gorman has been granted six months' leave of absence home from Calcutta on medical certificate Major J Poe has been appointed to the Eastern Command Major C H Furnivall has taken up duty at the *Military Hospital, Karachi on transfer from the Fourth* (Quetta) Division Major W L Bennett, on return home from a tour of service at Bermuda, has been appointed to Pontefract Major A H McN Mitchell has been transferred from the Royal Victoria Hospital at Netley to Dover Major S F St D Gr [illegible] Families Hospi [illegible] of Women and [illegible] taken up duty as *Specialist in Ophthalmology to the Ninth* (Secunderabad) Division of the Southern Army in India Major E W Bliss has been appointed Specialist in Operative Surgery to the Fourth (Quetta) Division

Captain A M Bennett has been appointed Staff Surgeon at Mhow Captain E J Kavanagh has taken up duty in the Eastern Command Captain J James has arrived home from South Africa Captain V C Honeybourne has been appointed to the Irish Command Captain D P Watson has been appointed Clinical Pathologist at the Queen Alexandra Military Hospital Captain J A W Webster has been placed under orders for service abroad Captain D S Buist has taken up duty with the Egyptian Army Captain H B *Connell has arrived home for duty from* the Sierra Leone Protectorate Captain J James has been appointed to the Eastern Command Captain A G Wells has taken up duty as Specialist in Operative Surgery to the Lahore Division Captain B Johnson has been granted six months' leave of absence from India Captain P A Lloyd Jones has been transferred to the Aldershot Command Captain A S Williams has been appointed to the Irish Command Captain J H Gurley has taken up duty at the Royal Victoria Hospital at *Netley* Captain *A Dawson* has arrived home for duty from India Captain A C Vidal has been appointed to the Aldershot Command Captain E W M Paine has arrived home for duty from Calicut Captain H P Hart has been appointed to Wellington Cantonment Captain C Kelly has taken up duty at Woolwich Captain A W A Irwin has been placed under orders for duty in the Cork District Captain G I Dawson has taken up duty as Specialist in Electrical Science and Radiography to the Meerut *Division Captain* A M Pollard has arrived home from South Africa Captain F D G Howell has arrived home for duty from Lahore Captain R F O T Dickinson has been transferred from the Military Hospital at Delhi Cantonment to Bareilly Captain A H Bond has taken up duty at Limerick on transfer from Queenstown Captain T W O Sexton has arrived home for duty from Wynberg Captain A S Littlejohns has taken up duty in the Dublin District on expiration of leave of absence Captain A H Jacob *has joined at Dublin, on* transfer from the Curragh Camp Captain G H Stevenson has arrived home for duty from Ambala Cantonment

Indian Medical Service.

Colonel P. Hehir has been granted six months' leave of absence home from India.

Lieutenant-Colonel S. Browning Smith has been selected to officiate as Sanitary Commissioner in the Punjab, in succession to Lieutenant-Colonel E. Wilkinson, granted leave of absence. Lieutenant-Colonel W. [illegible] appointed a Member of the Bombay [illegible] Lieutenant-Colonel L. F. Childe, resigned. Lieutenant-Colonel J. J. Pratt has been appointed Lecturer on Tropical Diseases at the Westminster Hospital. Lieutenant-Colonel C. Duer has been granted an extension of leave of absence home from India for six months. Lieutenant-Colonel B. H. Deare has taken up duty as Principal and Professor of Medicine at the Government Medical College, Calcutta, during the absence on leave of Lieutenant-Colonel J. T. Calvert. Lieutenant-Colonel A. Colman has been appointed to Rawal Pindi as Civil Surgeon. Lieutenant-Colonel L. F. Childe has arrived home on leave of absence from India.

Major A. G. McKendrick has been granted two years' leave of absence home from India. Major McCarrison has been placed on special duty under the Director-General. Major W. Selby, D.S.O., has been appointed Professor of Surgery on the staff of King George's Medical College at Lucknow. Major T. Hunter has been granted nine and a half months' leave of absence home from India. Major D. McCay has been appointed Professor of Materia Medica at the Government Medical College, Calcutta, and Second Physician to the College Hospital, in succession to Lieutenant-Colonel B. H. Deare. Major S. R. Godkin has been appointed Specialist in Operative Surgery to the Ninth (Secunderabad) Division of the Southern Army. Major A. B. Fry has been granted seven months' leave of absence home from India.

Captain J. W. S. Babington has been selected for appointment as Specialist in Ophthalmology. Captain R. S. Kennedy has been appointed Medical Officer to the North-Eastern Frontier Military Police. Captain A. C. Munro has been appointed to the Substantive Medical Charge of the 128th Regiment of Pioneers, in succession to Captain W. J. Fraser. Captain W. L. Forsyth has joined the Madras Jail Department for a course of training.

Territorial Force.

Royal Army Medical Corps.

6th London Field Ambulance, Royal Army Medical Corps: Major (Honorary Major in the Army) William M. O'Connor to be Lieutenant-Colonel (dated March 31st, 1913).

Colonel Seely and the Health of the Soldier.

Colonel Seely, who attended a meeting at the Royal Army Medical College, Grosvenor-road, London, S.W., on April 29th, when the prizes were distributed to the successful students for the special course last session, paid a well-deserved tribute to the work of the Army Medical Service. The good results were due in a great measure, he said, to coöperation of the ablest minds in the civilian medical profession, who had worked for the common good of the army and of the Empire. There had been a rapid and continuous improvement in the health of the soldiers, and the change since the South African war had been astonishing. The army was now a place where disease was comparatively rare. A higher standard of physical strength in the British soldier had been attained, enabling him to withstand disease in peace and war. Physical training of the young should receive more attention than was at present bestowed upon it.

Medical Sickness and Accident Society.—The usual monthly meeting of the executive committee of this society was held at 429, Strand, London, W.C., on April 18th, Dr. F. J. Allan in the chair. The claim account for the quarter ending March 31st was presented and showed that the epidemic of influenza had bee[illegible] the medical profession as among the [illegible] new business during that period was well up to the average, and the appeal made by the chairman at the annual meeting to members to make the advantages of the society known to their colleagues had already stimulated inquiries. Information can be obtained from the secretary, Mr. B. Sutton, 33, Chancery-lane, W.C.

Correspondence.

"Audi alteram partem."

THE ROYAL MEDICAL FOUNDATION OF EPSOM COLLEGE AND THE ROYAL MEDICAL BENEVOLENT FUND.

To the Editor of The Lancet.

Sir,—The good work which is being carried out by the Royal Medical Benevolent Fund is deserving of generous recognition, and I trust that the leading article in your issue of April 26th, setting forth the claims of that fund, will bear fruit with the profession and the public. But as treasurer of the Royal Medical Foundation of Epsom College I feel it to be my duty to draw attention to one statement in that otherwise excellent article which is open to misconstruction and may give rise to the impression that the Royal Medical Benevolent Fund is the only organised agency for rendering assistance to the necessitous members of the medical profession.

The statement to which I refer is the following: "What we want to bring home to our readers, and through them to the public, is that in many cases a medical man through no fault of his own, and his dependents certainly through no fault of theirs, fall into absolute penury, in which plight *nothing may stand between the* [illegible] *such grants as the Royal Medical* [illegible] *or that private benevolence may supply.*" (The italics are mine.)

You, Sir, will recall the fact that the Epsom College Foundation gives annuities of £30 each to 50 aged members, or widows of members, of the medical profession, and provides a first-class education, together with clothing and maintenance, for 50 necessitous sons of medical men. A sum of close upon £4500 has to be collected annually in donations and subscriptions to [illegible] urgent objects. It is for fear that [illegible] decrease that I would ask you to permit me to remind your readers of the necessity for them.

In the article mentioned above you refer to the summaries that are published in The Lancet from month to month with reference to the cases which the committee of the fund is able to relieve; but the pensions and foundation scholarships provided by the College, as well as a large number of pensions which are paid out of special endowments, are awarded without any notification in the medical press beyond the official announcement issued *after* the annual general meeting.—I am, Sir, yours faithfully,

Henry Morris, Honorary Treasurer.

8, Cavendish-square, W., April 26th, 1913.

WHEN TO OPERATE IN APPENDICITIS.

To the Editor of The Lancet.

Sir,—The energetic and forceful contributions by Mr. Edmund Owen to the columns of The Lancet on appendicitis and its treatment by immediate operation should do much to impress the advisability of this procedure on hesitating members of the profession. He has placed facts before us with remarkable and characteristic lucidity; few will try to controvert them. It is unnecessary to recapitulate the circumstances which gave rise to the discussion at the Medical Society of London on this treatment. Now that the main contention has been permitted to exert its full influence, it may be well to put forward some points which are not without their interest and importance when this subject is under consideration. If this is not done it may be thought that Mr. Owen has made a new discovery—that we are far behind the age as regards the treatment of this disease and have learnt little from the wealth of material which has passed through our hands during the last few years. The advisability of early operation was long ago demonstrated by American surgeons and recognised in this country by those brought most frequently into contact with this disease. It is true that, for a time, operation in the quiet period was put forward as the safe treatment, but increasing experience showed that, although operation was safe then, it was much better to get rid of the diseased appendix before it had had power to do much harm.

[illegible] advocated early [illegible] e contributions [illegible] who brought forward statistics from many sources, including some of the principal continental clinics. Early removal has also been urged in "Diseases of the Vermiform Appendix and their Complications,"[1] whilst in 1911 I read a paper before the Wimbledon Medical Society on the same subject.[2] It is the only plan of treatment in a majority of the cases, for we cannot expect everyone to possess the knowledge which will enable him to differentiate the more dangerous types from those which will run a mild course and subside without surgical interference. Those who do not operate frequently, still less those who never see an operation, cannot form an opinion as to the morbid processes in the appendix which led to the symptoms and local signs present in the case. These men are in the position which we all occupied some years ago before the disease became so common. They recognise that the patient has appendicitis, and that is all that concerns them.

Most surgeons have for years, I venture to say, examined the appendix thoroughly after removal, and made a note of the result of this examination after the diseased structure has been opened up. To say that an appendix is gangrenous, or that it has perforated, is not enough; we want to know what causes the gangrene so frequently found in acute attacks, for it may depend on many things. To publish a series of cases of the early and successful removal of so many scores of acutely diseased appendices does not do more at the stage at which we have arrived regarding appendicitis than confirm our statement that early removal is the most satisfactory treatment. The larger the number of the cases and the better the results, the more satisfied are we that this is the right thing; but to say that the lives of all of them would have been lost had this method not been employed is incorrect, and surely to tell many patients that they will die unless they submit to immediate operation is wrong. It has frequently been proved to be so. Furthermore, I would add that an attempt to recommend operation indiscriminately without any endeavour to differentiate between the varieties and potentialities of the morbid processes causing the acute attack does not lead to the advancement of our clinical knowledge or to the credit of the profession. Time after time a case is seen in which the question arises, Must operation be done at once? for there are many reasons why it should be postponed unless it is imperative.

There never was a time when the general practitioner was so well educated or so well fitted to deal with abdominal emergencies. It is even possible that he may sometimes be too eager to exercise his skill. There is a growing reluctance to call in a doctor who always operates at once, because the idea prevails that if the patient has a stomach-ache, whether due to indigestion, constipation, influenza, or other common cause, the doctor will want to open the patient up. This is a great pity, because it leads to loss of valuable time in really grave attacks, for the friends wait to see if the child will not improve.

Contrary to the opinion of Mr. Owen, I believe that many practitioners can give quite correct opinions as to the course of a particular attack, whilst surgical consultants can speak with considerable accuracy as to the nature of the process which has commenced in the appendix. We have had much experience during the past 20 years derived from constant observation and practice, whilst those in general work have been better instructed in the varying phases of the disease. Far more of the urgent cases are sent to the hospitals within the first 24 hours of illness than was formerly the case, the appreciation of the clinical condition is made earlier, and the operation is done as soon as possible in most institutions. In spite of this the supply of patients applying for operation in the quiet interval shows little diminution. Appendicitis is a septic disease, and will always be dangerous to the individual affected because of the nature of the membrane by which the organ is surrounded and the position which it occupies. There are also many types according to the primary cause of the attack, its extent, the history of previous attacks, the age, sex, and power of resistance of the individual.

Experience will give the skill to say what is going on in the appendix, and long and constant observation has already given it to many. It is essentially a practical knowledge and cannot be gained simply by reading symptoms in a book. Those who have it are justified in permitting a departure from what should be the recognised rule of treatment—early removal of an appendix which is giving signs of disease.

A consideration of some of the side issues raised by the discussion at the Medical Society and by the correspondence in THE LANCET cannot be satisfactorily undertaken in any journal, however generous the editor might be in affording the hospitality of its columns.

I am, Sir, yours faithfully,
London April 25th, 1913. WILLIAM H. BATTLE.

INSANITY AND DIVORCE.

To the Editor of THE LANCET.

SIR,—It is immaterial what the exact wording of the recommendations of the Royal Commissioners on Divorce may be; what I object to is the principle, as stated by "E. A. A.," that "incurable (?) insanity should form a ground for divorce after five years' confinement," even when safeguarded by the opinion of two experts. There are a large number of cases on record in which recovery has taken place after five or more years' detention in an asylum, who were at the expiry of the proposed term apparently incurable. Expert evidence is not always infallible, and, to say the least of it, is at times contradictory.

I admit that cases occasionally arise in which curable or incurable insanity may be a great hardship, but in my experience these have almost invariably been cases in which previous attacks of insanity have been wilfully concealed. This, I think, is a perfectly legitimate ground for divorce. "E. A. A." has not, however, criticised my chief objection to the Royal Commissioners' report—viz., "Why should insanity be pilloried as a ground for divorce more than any other form of incurable illness, which is not directly due to evil living." I am, Sir, yours faithfully,

J. BATTY TUKE, jnr., M.D.
New Saughton Hall, Polton, April 26th, 1913.

INTRACRANIAL COMPLICATIONS OF MIDDLE-EAR DISEASE.

To the Editor of THE LANCET.

SIR,—I have read with very great interest the article by Mr. Hunter F. Tod, in THE LANCET of April 19th, on Extradural Abscess at the Apex of the Petrous Bone.

Let me say at once, I am not an aurist and lay no claim to knowledge on that subject except in so far as relates to intracranial disease. Without criticism, and in an inquiring spirit simply, I wish to ask Mr. Tod if, in his experience, the commencing statement he writes is undeniable—viz., "*An extradural abscess is the most frequent complication of acute inflammation of the mastoid process, being due to direct extension of the infective process through the bone to the outer surface of the dura mater, and is almost invariably found in the region of the tegmen tympani or of the lateral sinus, the latter being most frequent.*" Being a disciple of [illegible] on the "P[illegible] Cord," for [illegible] (I hope) an interested *observer of all surgical brain cases*, I am naturally influenced by such causes, and wish to state simply and briefly my experience of intracranial suppuration and an easy way of grouping complications. Geometrically considered there are six simple directions in which infective spread may occur from the middle ear—namely, (1) backwards, (2) forwards, (3) upwards, (4) downwards, (5) outwards, and (6) inwards.

1. Backward spread is the most important, leading to infection, *viâ* the iter, of the mastoid antrum, followed by rapid sepsis of the communicating cancellated bone and the horizontal and vertical mastoid cells. The mastoid bone is made up of spongy tissue, and its infections are really in the nature of osteomyelitis. Further backward spread involves, first, the space around the sigmoid portion of the lateral sinus; next the sinus itself (infective sinus thrombosis); then the membranes, causing extradural abscess or meningitis; or, lastly, the meninges in relation to the cerebellum under the

tentorium may rapidly become "soldered" by inflammation (Macewen) conveying the sepsis through it directly to the cortex, resulting in cerebellar abscess.

2. Forward spread means repeated attacks of sore-throat from pus travelling down the Eustachian tube, or in rarer cases infection of the temporo-maxillary articulation.

3. Upward spread through the tegmen tympani or tegmen antri results nearly always in "soldering" of the membranes which are closely in contact with the bone by the temporo-sphenoidal lobe of the cerebrum lying over and pressing on it, and thus almost direct extension into the brain with temporo-sphenoidal abscess results. There is here technically an extra- and intra-dural inflammation, but practically an abscess of the brain. Meningitis with pus formation from this mode of spread is thus extremely uncommon.

4. Downward spread of the infection, involving the vertical cells of the mastoid, in cases where a foramen exists on the deep side of the process, results in Bezold's mastoiditis or suppuration in the posterior triangle of the neck, the pus following the origin of the posterior belly of the digastric muscle.

5. Outward extension is by far the least serious, resulting in a so-called "periostitis" under the temporal fascia, with characteristic downward and forward displacement of the auricle. This form of disease is especially common in children in whom the petro-squamosal suture is open, and accounts for the lesser seriousness of mastoiditis, this suture at times opening directly into the antrum and exercising a safety-valve effect on pus formation.

6. Lastly, inward extension is characteristic. Here the facial nerve may be pressed on or ulcerated, the middle ear may be destroyed, or the internal auditory meatus involved. In the latter case the brain itself is not first reached, but sepsis implicates the glove-like sheath of membranes containing cerebro-spinal fluid, nerves and vessels, and spreads in the subarachnoid space; thus typical acute lepto-meningitis will follow, and not brain abscess.

My interest in Mr. Tod's case leads me to hope that he may set down his views on this important subject.

I am, Sir, yours faithfully,
SPENCER MORT, M.B., Ch.B. Glasg.

Edmonton Infirmary, April 23rd, 1913.

IODOFORM INJECTIONS IN PULMONARY TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—In THE LANCET of April 12th there is a letter by Dr. E. Curtin, of Bournemouth, giving his experience of the value of intravenous injections of iodoform in pulmonary tuberculosis. Dr. J. Bain, of South Shields, and Dr. Mervyn Crofton, of University College, Dublin, have, in the *Glasgow Medical Journal*, 1909, and the *British Medical Journal*, 1912, recorded similar experiences. I shall be very much indebted to any readers of THE LANCET if they will kindly furnish me with references to other publications, or personal experiences of the method, with details of the cases in which iodoform failed and in which it succeeded.

I am, Sir, yours faithfully,
THOMAS W. DEWAR.

Kincairn, Dunblane, N.B., April 26th, 1913.

*** The subject of iodoform injections in pulmonary tuberculosis was discussed at a recent meeting of the Section of Medicine of the Royal Academy of Medicine in Ireland, reported on p. 1244 of our present issue.—ED. L.

THE MILWARD FUND.

To the Editor of THE LANCET.

SIR,—May we venture to draw the attention of your readers to the above fund? William Courtenay Milward died quite suddenly at Cardiff on April 9th, aged 41. Practically no one knew that he was ill. He has left a widow and three young boys, and they are almost without means.

For the last year and more Milward, as the senior secretary of the Cardiff division of the British Medical Association, and in other capacities, has worked enormously hard for the local profession, and undoubtedly this extra work helped to bring about his death. The fund will be administered as a trust for the benefit of the dependents. It is already nearly £600, besides a number of promises of so much a year for five years. This has almost all been obtained locally. It is possible that there may be some in a wider professional circle who would like to contribute—some who knew Milward, others who sympathise with the circumstances of his death. Hence this letter. Any further particulars may be obtained from, and contributions will be gratefully received by, us. We are, Sir, yours faithfully,

WILLIAM SHEEN,
2, St. Andrew's-crescent, Cardiff (honorary treasurer).
A. L. THORNLEY,
18, Windsor-place, Cardiff (honorary secretary).

April 29th, 1913.

THE MEDICAL PROFESSION AND THE NATIONAL INSURANCE ACT.

To the Editor of THE LANCET.

SIR,—The following note may be of interest to your readers as throwing a sidelight on the working of the National Insurance Act in this district. I may first mention that the nearest town to this village is eight miles distant, and that I am not on a panel.

Towards the end of November last a patient of mine in the village—an insured person and the secretary of an Approved Society—sustained a transverse fracture of the patella. When Jan. 15th approached he decided to wait, at any rate until I was finished with his case, before sending in his name for acceptance by a panel doctor in the nearest town. At the beginning of February I told him I would require, about the end of the month, a Middlesex splint for his use for some months.

The question naturally arose as to whether he was to provide the splint, at a cost to himself of 45*s*. to 65*s*., or ask to have it granted by the Insurance Committee in virtue of the fact that he was entitled to it in terms of the Act. I advised him to write to the Insurance Committee stating the whole circumstances of the case, with particular reference to the date of the accident. Back came a reply to the effect that the Commissioners for Scotland had been consulted and that they had refused to sanction the provision of this very necessary appliance unless it was ordered by a panel doctor.

I am, Sir, yours faithfully,
JOHN J. ROBERTSON, M.B.

Portpatrick, Wigtownshire, April 29th, 1913.

THE POSITION OF ASSISTANT MEDICAL OFFICERS IN ASYLUMS.

To the Editor of THE LANCET.

SIR,—Anything written by Dr. Robert Jones on asylums must command every attention and respect. Everybody who knows anything about these institutions is aware of the position he occupies and the great authority with which he speaks. While not denying the successes attained by men working under such an eminent psychiatrist, might I respectfully point out that the promotions in asylum work achieved by his assistants and those of his distinguished *confrère*, naturally leave rather little for those outside their charmed circle. To return, however, to my original contention about the suitability of asylum experience as a preparation for general practice, Dr. Jones gives a list of 12 operations altogether performed in his asylum in 12 months. He has six assistants. If they did them all it would be two apiece. Surely they would on this count have better opportunities in institutions entirely reserved for the physically ill. As regards studying for the M.D. and F.R.C.S., might I ask what then becomes of the study of psychiatry? It would be a great testimonial to any assistant to base his knowledge of psychiatry on the knowledge required for these qualifications, but if he goes into the service to get leisure to read for them, and rushes out of it again when he gets them, what can any reasonable man conjecture? Under the stimulus of specialists like Dr. Jones men may do many things, but even in spite of his great inspiration it must be a work of much difficulty, withdrawn as they are from the general hospitals and schools. Would it not be better to face the fact that asylum work is special work in itself, requiring a very special temperament and training, and make a service of it that the average man could go into feeling he would get reasonable advancement for his work and increasing knowledge of his specialty, and not spend his time trifling with allied subjects or games until chance or other circumstances, often remote from his ability, get him on.

I am, Sir, yours faithfully,
April 28th, 1913. REFORM.

MEDICAL PRACTICE UNDER THE INSURANCE ACT.

(BY OUR SPECIAL COMMISSIONER.)

(*Continued from p. 1207.*)

VIII.—THE SCOTTISH MINERS AND THE ACT.

Bothwell as a Mining Centre.

BOTHWELL is close to Glasgow, and is the centre of the neighbouring mining industries. It is in the county of Lanark where there are many coal pits, so this is a good place to ascertain how the Insurance Act is affecting the miners and their medical attendants. Before the Act every adult miner, whether married or single, paid 6*d.* per fortnight, or 13*s.* a year, for medical attendance and medicine for himself and his family. Their medical attendants were known as the colliery and public works surgeons—a somewhat misleading title, because they are not attached to public works but to pits and various other works belonging to private companies and owners. It was these owners who appointed the "works doctor," as he is colloquially called. Thus a pit employing, for instance, 600 adult miners, from whose wages 13*s.* per head was deducted annually for medical attendance, meant a medical living, if I may use the clerical term, of £390 a year.

Practice and Patronage.

From the point of view of the progress of science, was it a good thing that colliery owners or managers of great works should have the power of thus conferring livings, some fat, some lean, on members of the medical profession? Were those who exercised this very important patronage competent judges? A good many persons thought that here we had a very serious abuse, and now the National Insurance Act has swept it all away. To-day no such patronage is possible. The practitioner who was the special favourite of the factory or mine owner must put his name on the panel, take his chance with all the other practitioners, and if he has many patients it is because he is popular among the workers, among those who are to be his patients rather than among their employers. This in itself is quite a revolution. One among those who must have been a loser under the new *regime* nevertheless remarked to me that the change was not altogether a bad thing, though the sufferers naturally did not like it.

Every practitioner in Lanarkshire is on the panel, and the works doctors, who previously had a secure income, dependent, of course, upon patronage, now hardly know how they stand. Formerly, and wherever he might live, the miner had to go to the practitioner attached to his pit. As the miners were not all able to get house accommodation close to the colliery where they worked, the works doctor to attend them was often obliged to travel over considerable distances. Now that there is free choice of medical attendant many of the insured persons have left their former works doctor and put their names on the list of a panel doctor who lives nearer at hand. Thus, works doctors have lost many old patients, but some have gained many new ones.

The Attitude of the Insured Patients towards their Medical Advisers.

So far as the relations between the practitioners and their patients are concerned there is no difference in the behaviour of former club patients and the care they expect to receive. There is, however, a great difference when dealing with the newly insured. Thus, one of the leading local practitioners declared to me that he had seen more domestic servants since the Act came into force than during the last five years. Then he had any number of railway servants, stonemasons, carpenters, and skilled artisans generally, who came to him now as insured persons, while formerly they used to consult him, less frequently it is true, but they all paid fees. There were few Friendly Societies in the neighbourhood of Bothwell, and many of those who belonged, for instance, to the Oddfellows, were miners. Consequently, they were entitled to the care of their works doctor. If they also paid for medical aid through their Friendly Society they might have the choice of two medical attendants, for they paid for both. Altogether, and in their dealings with the adult male population, who for the most part are miners, not only have medical men no general cause of complaint, but it seems that, if taken as a whole, the position of the colliery surgeons has improved, though individuals here and there may undergo some loss.

The Medical Contract with the Miners' Federation.

The medical practitioners at Bothwell and for many miles round have, however, other anxieties. The population does not consist only of insured persons. The old scheme of insurance such as it was secured medical attendance for the families, and these are entirely neglected by the Insurance Act. In providing for these dependents the medical practitioners have to deal with the Miners' Federation of Scotland, which is a branch of the Miners' Federation of Great Britain, and this in its turn is a branch of the International Federation of Miners, which has many thousands, perhaps some millions of members, and sends direct representatives to the House of Commons and the principal Parliaments of Europe. Facing such an organisation, with its expert leaders and committee men, its delegates well trained in the art of negotiating on behalf of large bodies of men, the members of the medical profession, who have had so little experience in organisation and collective action, find " [illegible] Miners' Federation, [illegible] in taking action in [illegible] s an Association of Public Works Surgeons with whom the Miners' Federation could negotiate. The Public Works Surgeons' committee for Scotland and the Miners' Federation met on several occasions during January and February, and finally signed an agreement which, however, is terminable on either side after a month's notice. The terms then accepted were a flat rate to be paid by all adult males, whether married or unmarried, this to be deducted from their wages by their employers. The amount is 2*d.* per week, and for this medical attendance and medicine are to be given to the wives and children—in fact, the non-insured dependents. If the medical practitioner provides the medicine he is to receive the 2*d.*, or 8*s.* 8*d.* per annum. If not, a ½*d.* would go to the dispensing chemist. No part of the 2*d.* is to be deducted for working expenses or management, and in this agreement the miners were careful not to allow a privileged set of works doctors to be brought back into existence. On the contrary, they enforced what the Act had given in regard to insured persons by insisting that there should also "be free choice of doctor for the wives and families, subject to the consent of the doctor to act." This agreement has been signed not only on behalf of the miners of Lanarkshire but several other Scotch counties.

Formation of a Fighting Medical Union.

It was quite obvious, from the various conversations I have had on the spot, that a good many medical men feel not a little humiliated by the obviously inferior position they hold when face to face with the great trade unions of this country, and especially the Miners' Federation. The medical profession has no direct representatives in the House of Commons, it has no discipline, and it has no strike fund to back a fight when a fight is necessary. "What we must have," said one of the leaders of the profession in Lanarkshire, "is a medical union organised on absolutely the same lines as a working man's trade union. We have lived among trade unionists all our lives, we know what trade unionism means, and we appreciate its value, whereas a large number of members of the British Medical Association know nothing whatsoever about trade unionism. In fact, they rather despise it and consider themselves above that sort of thing—above using the only effective weapon at our disposal. Our bread and butter depends on the spirit of trade unionism we can develop in our ranks." Within the last few weeks, I was assured, nearly every practitioner in Lanarkshire had signified his readiness to join a fighting union and help to build up a strike fund. An executive committee with chairman had been appointed, as also a paid secretary. In regard to the latter post, they meant business. They were not going to elect some eminent medical man who stood high in the ranks of his profession and had distinguished himself in his science. What had that got to do with organising a movement to raise practitioners from real poverty? They had appointed for secretary a solicitor who would keep them on the right side of the law and see there were no flaws in the contracts they might have to sign. In Midlothian a practitioners' union was being formed on similar lines, and in Ayrshire the members of the profession are showing a dissatisfaction which may be expressed in a similar way.

Increase of Miners' Contributions for Medical Service.

In the face of such a bellicose spirit it seemed to me as though the Insurance Act has greatly changed the views of medical practitioners. It has engendered the spirit of organisation, and suggested the possibility of collective action. Everywhere the same observation has been made to me in all the places that I have visited. The Act has brought the members of the profession closer together; and, with the growth of strength which union secures, grievances that have been endured because remedy seemed hopeless are now brought forward as having entered the domain of practical politics. Thus, at Bothwell, I found medical practitioners distinctly militant in their intention to stand up for their professional rights; yet, instead of having some new cause of complaint, it can be argued that their material position had been improved, in any case so far as the miners are concerned. Formerly, one married and one unmarried miner (50 per cent. only of the miners being married) paid each 13*s.* a year. Estimating the family of the married man at five, this makes 26*s.* a year for a total of six persons. For this sum they all received medical attendance and medicine. To-day these two men are insured persons and 8*s.* 6*d.* is paid on their behalf under the Act, so that they may get medical attendance, special tuberculosis treatment, and medicine. This is an annual total of 17*s.* Then these two men also pay 2*d.* a week each, or 8*s.* 8*d.* a year, and that is a total of 17*s.* 4*d.*, to secure medical treatment and medicine for the wife and children. Thus the medical profession and the dispensing chemist obtain under the Act, and in accordance with the agreement concluded with the Miners' Federation, an annual total of 34*s.* 4*d.* for attending to six persons; whereas before the Act they only received 26*s.* This is undoubtedly a very substantial increase. There may be losses in other directions, but so far as the miners are concerned more is paid than was ever given before for the medical attendance they receive, and they constitute the vast majority of the population at Bothwell. The position would not of course be so favourable if a larger proportion of miners were married, if the bachelors were to refuse to help in bearing the married men's burdens, or if the average of five per family proved to be below the actual figure.

If it came to reopening the negotiations the colliery surgeons feel that they stand unarmed in front of so formidable an organisation as the Miners' Federation. By its influence in Parliament, where so many miners, men who have actually worked in the pits, occupy safe seats, by its discipline, by its financial resources, amounting to some millions sterling, the Miners' Federation stands like a giant by the side of whatever pretence at organisation the medical profession may possess. The medical advisers to the middle and upper classes who live in residential districts and fashionable quarters have no conception of these things. But the colliery surgeon sees what the forces of organised labour can do, and he bitterly resents the inferior organisation and comparative weakness of his own profession.

(To be continued.)

ROYAL INSTITUTION OF GREAT BRITAIN.—A course of three lectures on Recent Physiological Inquiries by Professor W. Stirling, M.D., is now in progress at the Royal Institution, Albemarle-street, London, W. The lectures will be illustrated by means of the kinematograph, epidiascope, autochrome, and other lantern slides and by experiments. The first lecture, on Tuesday last, was on Motion and Locomotion. Lecture II. will be delivered at 3 P.M. on Tuesday, May 6th, on Equilibration and the Sixth Sense, and Lecture III. will be delivered at 3 P.M. on Monday, May 12th, on Ductless Glands and their Dominating Influences.

THE GERMAN SURGICAL CONGRESS.

(FROM OUR BERLIN CORRESPONDENT.)

(Concluded from page 1200.)

Collargol in Septicæmia and Cancer.

Professor KAUSCH (Berlin) said that in septicæmia with remittent pyrexia collargol had always been efficacious, but that in cases with continuous pyrexia there was little effect. It was, however, very useful when there was continuous pyrexia after the opening of an abscess. Intravenous injection was the best method of administration; rectal injection was not advisable unless intravenous injection was not allowed by the patient. The usual dose was 10 grammes of a 2 per cent. solution. When the effect of this was insufficient, or the case was very severe, from 20 to 30 grammes must be injected daily or every second day. Professor Kausch also treated 11 cases of inoperable cancer by large doses of collargol up to 100 grammes, combined with Roentgen rays. None of the patients recovered, although a case of cancer of the liver was temporarily relieved. One patient died three days after the injection of 80 grammes, and at the necropsy the kidney was found to be obstructed by a silver precipitate.

Operations on the Brain.

Professor VON EISELSBERG (Vienna) reported the results of his operations for tumours of the brain. He had operated upon 162 cases. Growths of the cerebrum occurred in 69 patients, and in 40 of the cases they were removed, with 9 deaths—5 from meningitis, 3 from shock, and 1 from pneumonia. At a later period 8 patients died from various causes, including a relapse of the growth and prolapse of the brain; 6 were improved, and 9 recovered. In 16 cases growths of the hypophysis were operated upon. In 33 cases an operation was performed for tumours of the cerebellum, 17 for tumours of the auditory nucleus. The latter had the worst prognosis, as 11 out of 17 patients died. In 29 cases trephining was performed for palliative reasons. Previous to the operation lactate of calcium and urotropine were administered. The operation was usually performed under local anæsthesia. Hæmorrhage of the bones of the skull was stopped by driving in wooden pins. The operations were as a rule made in two stages and drainage was avoided. Osteoplastic methods were not employed in operations on the cerebellum. Tumours of the auditory nucleus were operated on according to Krause's method.. Defects of the dura mater were covered by plastic flaps of the fascia, so that the danger of infection was considerably diminished. Nevertheless, 11 patients died from meningitis and 19 from shock. Although the prognosis of the operation was unfavourable, it must be considered that the cases themselves were very sad.

Operations on the Spine.

Professor RANZI (Vienna) reported 40 operations on the spine performed in Professor Eiselsberg's clinic. Of these patients, 17 suffered from growths, 5 from fractures, and 2 from spondylitis; there were also 16 cases of Förster's operation. The operations were performed under general anæsthesia with injections of adrenalin. The vertebral arches were always removed. In opening the dura mater a quick discharge of the cerebro-spinal fluid must be avoided The dura mater must be opened, even when the growth had an extradural position, because multiple growths might be present. In Förster's operation the extradural procedure, according to Guleke's method, showed a remarkable progress After the operation the dura mater must be exactly sutured and plugging must be avoided. Of the 40 cases, 30 ended fatally. Of the various growths, the extradural had the best prognosis. Förster's operation was especially efficacious in spastic paresis of the lower extremities.

Professor KÜTTNER (Breslau) gave a report of his operations for cerebral tumours. He stated that an early diagnosis was very difficult. Trephining was frequently performed in doubtful cases above and below the tentorium. He had obtained good results by puncture according to Neisser's and Pollack's method, but the effect produced by puncture of the corpus callosum was less favourable. He operated in two stages under local anæsthesia and made an osteoplastic flap. Suturing of the dura mater was seldom performed. He had operated in 92 cases with a primary mortality of 30·5 per cent. A permanent recovery was obtained in 30·5 per cent.

Professor OPPENHEIM (Berlin) stated that the prognosis of operations for tumours of the brain had become worse of late years, the reason being in his opinion that a large proportion of doubtful cases were now operated on and that the indications for the operation have been extended.

Professor SCHLOFFER (Prague) read a paper on operations for visual disturbances caused by "tower skull" (Turm-Schädel). He said that he had removed in two cases the upper wall of the optic canal after having previously lifted temporarily the frontal bone with the dura mater. The patients were two boys in whom other operations (puncture of the corpus callosum and trephining) had been inefficacious. In one of the cases the eye, which hitherto had been amaurotic, had a perception of light three weeks after the operation.

Professor RITTER (Posen) described his method of arresting hæmorrhage in operations on the brain. He made the carotid arteries on both sides accessible and applied a clamp forceps temporarily. A complete arterial anæmia of the brain was obtained at once and the hæmorrhage from the veins stopped after a short time. He had operated in this way on three cases, the lesions being respectively fracture of the skull with depression, subcortical tumour, and purulent mastoiditis. The patients bore the operation very well. From the moment when the forceps was applied no anæsthetic was wanted; they awoke very soon and did not vomit.

Operations on the Kidney.

Professor KÜMMELL (Hamburg) gave a report of his definitive results in 386 cases of nephrectomy. He said that in tuberculosis recoveries were obtained in 80 per cent., in malignant growths in 40 per cent., in hydronephrosis in 98 per cent., and in pyonephrosis in 90 per cent. Unilateral mechanical injuries had a good prognosis, but Bright's disease a bad one. In polycystic degeneration nephrectomy was contraindicated. In tuberculosis a definitive recovery might be presumed after two years, and in cancer after four years if no relapse has occurred within these limits. A great number of the patients who had been operated on died within the first year. An affection of the other kidney in tuberculosis made the prognosis worse, but in some cases recovery occurred nevertheless—in one case after an incision of the kidney. Women with one kidney passed through pregnancy tolerably well, for among 17 cases Bright's disease and premature birth occurred respectively only once. Morphine, ether, and diphtheria antitoxin were well supported by patients with one kidney, but veronal and chloral badly.

Dr. BÄTZNER reported the results of 100 cases of nephrectomy performed in the Berlin University Clinic from 1901 to 1912. In 9 cases there was a fatal issue in connexion with the operation; of the remaining patients 28 died from accidental diseases, 3 from uræmia, and 60 were still alive. The worst results were obtained in cases of malignant growth, as all the 18 patients died from a local relapse or from metastases. The results in cases of hydronephrosis and of pyonephrosis were very good, and so were those in cases of Bright's disease, acute inflammation of the kidney, and tuberculosis.

Dr. VOELKER (Heidelberg) said that tuberculous foci in the kidney might heal up spontaneously, but that the tissue of the kidney was destroyed. Conservative treatment must therefore be deprecated even in slight cases.

Thymectomy for Graves's Disease.

Professor VON HABERER (Vienna) said that he had performed thymectomy in four cases of Graves's disease. In a fifth case the thymus gland was removed for symptoms of stenosis. The operations were successful. He mentioned especially a case in which grave symptoms were present and became worse after resection and ligature of the thyroid gland. Thymectomy was then performed, but only a rather small thymus body was found. Nevertheless, the success was striking; the dilatation of the heart no longer existed, the pulse-rate fell to 84, the nervous symptoms and the congestion of the liver disappeared, and the patient was able to engage in mountain climbing.

Operations on the Gall-bladder.

Professor KEHR (Berlin) reported the results of 2000 operations on the gall-bladder. Comparing his second with his first 1000 he said that the general mortality had become worse owing to the increase of malignant cases. The mortality of operations for gall-stones had decreased, especially in the cases in which the operation included draining the hepatic duct. Cystotomy has altogether been abandoned. As one result of his large experiences, he said that peritonitis was no longer met with as a sequel of operation, neither was there any infection of the wound when the subcutaneous fatty tissue was not sutured. The danger of hæmorrhage in icteric patients was still rather great; there was only one remedy against it—namely, an early operation before cholæmic symptoms appeared.

Military Surgery.

Dr. GOEBEL (Breslau) described some of his experiences at the war in Tripoli. He mentioned lesions caused by bombs thrown from aeroplanes; they were distinguished by their multiplicity, by the localisation of the lesions on the lower extremities and the trunk, and by a characteristic course of the track of the projectile through the tissues. They were caused mostly by shrapnel bullets. In Tripoli enteric fever showed many surgical complications, including abscess of the parotid gland, empyema, abscess of the appendix vermiformis, and gangrene of the leg and the toes.

Dr. COENEN (Breslau) reported his experiences in Athens during the Balkan war. He had treated 665 patients suffering from gunshot wounds, of whom 7 died, whilst 75 per cent. recovered without any complication. Thirty cases of severe cellulitis were treated by large incisions and in four instances by amputation. Among 23 cases of wounds of the joints, 4 resections and 1 amputation were performed; the other patients recovered without operations. Of 94 compound fractures, 83 healed by primary union, 11 with complications and 1 case after amputation. Aneurysms occurred in 5 cases; they were operated on when they had become encapsuled. Wounds of the spine gave a bad prognosis owing to the occurrence of bedsore and infection of the bladder.

Dr. KIRSCHNER (Konigsberg) gave an account of his experiences in Sofia and Mustafa-Pascha with the Bulgarian forces. Owing to unsuitable transport arrangements and defective first-aid, secondary infection of wounds of the bones, the vessels, and the joints was frequently observed. The wounded arrived at the hospital in a state of exhaustion. Immediate fixation of these wounds by a plaster bandage at the dressing-station was absolutely necessary. For wounds of the soft tissues the starch mastisol dressing was the best method.

Dr. FRANK (Berlin), who had worked in an intermediate hospital with the Greeks, said that the first field dressing carried by each soldier had been very useful. Mastisol proved to be a barrier, not only against bacteria, but also against vermin. Wounds caused by artillery bullets often became infected. Erysipelas was seldom observed and tetanus never Pyocyaneus infection was frequent. Meningitis often occurred when trephining had been performed in the dressing station. Wounds of the calf of the leg were frequent, and were of bad prognosis with respect to the recovery of function.

Dr. GOLDAMMER (Berlin) expressed the opinion that the frequency of infections was somewhat underestimated, according to his experiences in a hospital of the first line where the infected patients were left who could not be transported to the base hospitals. He had obtained good results in the treatment of infected wounds by the use of passive congestion according to Bier's method.

Dr. VERTH (Kiel), a naval surgeon, spoke on the peculiarities of wounds inflicted in a naval engagement according to experiences in the Russo-Japanese war. In a naval engagement the majority of wounds were caused by artillery fire, mines, and torpedoes. In the above war 75 per cent. of the wounds were due to artillery and 25 per cent. to mines and torpedoes. When an encounter took place on an average 20 per cent. of the crew were injured, of whom 4 per cent. died; 8 per cent. were severely, and 8 per cent. slightly, wounded. Concerning the wounds themselves, he stated that one-quarter of the wounds were contusions, one-third were contused wounds, one-sixth were penetrating wounds, one-tenth were mutilations, one-tenth were burns, and one-tenth were lesions of the eyes and the ears. Injuries of the viscera might be expected in about 5 per cent., and fractures in 20 per cent.

Dr. CLAIRMONT (Vienna) read a paper on Gunshot Wounds of the Skull. He said that these wounds must always be regarded as infected because the brain did not overcome slight infection as easily as other parts of the body did. Tangential wounds gave the worst prognosis and required surgical interference at all periods.

Considerations of space preclude an enumeration of the numerous other papers read at the meetings.

Professor MÜLLER (Rostock) was elected President of the next Congress.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Medical Certification under the National Insurance Act.

THE Insurance Commissioners last week summoned conferences between representatives of the Insurance Committees and of the Approved Societies in the various areas where the panels have failed to fill. In Dublin the conference was held last Monday, and a discussion took place on the question of appointing whole- or part-time referees, but it was felt that such a step would lead to unpleasant friction between the medical attendants and the certifying referees. Eventually a resolution was adopted requesting the medical profession to reconsider the question of fees, and to appoint a delegation with full powers to meet the conference. Failing action by the profession, the conference recommended that the Commission should hand over to the societies their appropriate share of the grant, and that the societies should be left to make their own arrangements. It is believed that if the societies get control of the grant they will be willing to pay a fee of 2*s.* 6*d.* per certificate, the sum demanded by the profession. Indignation has been roused among the medical men of county Longford by the statement of the chairman of the Insurance Commission that a panel had been "completed" in that county. It is stated by the Local Medical Committee that it holds the written pledge of every medical man practising in the county not to go on the panel. It is to be noted that the Commissioners have not yet divulged the names of those said to be on the panels. At the meeting of the Conjoint Committee on April 26th a resolution was passed pointing out to the Commission that the attempt to obtain medical certificates from medical men other than those in attendance on the patients would be in contravention of the recognised ethics of the profession. A discussion also took place with reference to a pledge said to have been given on behalf of the Irish Parliamentary party to obtain for the medical profession a minimum capitation fee of 2*s.* 6*d.* for certificates. Having heard the statement of Mr. Thomas Hennessy, supported by letters from Mr. J. C. Lardner, M.P., Mr. J. Cullinan, M.P., and Mr. J. S. McArdle, the Committee was of opinion that the National Insurance Act Committee of the Irish party had made a definite offer to the profession of the fee named.

The Poor-law Medical Officers' Committee (I.M.A.) at their meeting in Dublin on April 21st passed a series of resolutions condemnatory of the arrangements for certifying under the National Insurance Act, and severely criticising the action of the "Conjoint Committee." The Belfast board of guardians have asked for a return from their dispensary doctors showing the proportion of insured persons treated in the dispensary (Poor-law) for the quarter to the end of June to see if it is true—as alleged—that Friendly Societies in Belfast were getting the benefit of the Poor-law dispensary for their members. The medical practitioners of Lisburn have founded an association, and have agreed not to form a panel for certification under the National Insurance Act. It is also said that the rural doctors around Lisburn have decided not to go on the panel. At a meeting of Friendly and Approved Societies held in Belfast on April 22nd the feeling was so strong against bringing in the dependents—should medical benefit become extended to Ireland—that when a resolution was proposed advocating this plan it found no seconder. The meeting instructed their delegates to the London Conference to ask that if medical benefit was extended to Ireland it should be done simply as it is being worked in England.

The Meath Hospital.

The annual meeting of the Meath Hospital, Dublin, was held last Monday. The report for the year stated that there were in the wards of the hospital on April 1st, 1912, 121 patients; 1379 were admitted during the year, making 1500. Of these, 1273 were discharged cured or relieved, 105 died (25 being moribund when admitted), and 122 remained on March 31st, 1913. The total number of days spent in hospital was 42,214. The average daily number of beds occupied was 115·66. The average number of days spent in hospital by each patient was 30·61, and the mortality was 7·62 on the total treated to a termination. There were also 9840 accident cases treated as out-patients, and the dispensary cases numbered 9544. There was, therefore, a total of 20,884 persons who received medical or surgical treatment during the year. The number of attendances at the out-patient departments amounted to 31,736. There was at the commencement of the financial year a debit balance of £7528 17*s.* The total expenditure was £7294 1*s.* 11*d.*, and the total ordinary income £6313 11*s.* 6*d.*, showing a deficiency on the year of £980 10*s.* 5*d.*, which increased the debit balance to £8509 7*s.* 5*d.* The managing committee fears that unless more voluntary subscriptions are received it will be compelled to curtail the number of beds.

Belfast Nervous Diseases Hospital.

At a special meeting of the committee of management of the Hospital for Nervous Diseases, Belfast, held on April 25th, a minute was adopted expressive of the deep loss the institution had sustained by the death of Dr. J. M. MacCormac, who 16 years ago founded the hospital, and appreciative of his good work there. An extract of this minute was directed to be sent to Mrs. MacCormac.

April 28th.

ERRATA.—Mr. H. W. Bailie, medical superintendent officer of health of the city of Belfast, writes to correct two inaccuracies in the Irish letter in THE LANCET for April 19th, p. 1130. The number of cases of diphtheria notified since October, 1912, was 182, not 300, and the number of cases notified in March was 34, and not 154, as stated by our correspondent.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Obituary.

TWO members of the Academy of Medicine have died in the same week—viz., Professor Jaccoud and M. Yvon. Professor Jaccoud had been permanent secretary of the Academy since 1901. He attained a distinguished position in medicine without any initial advantages. He defrayed the heavy cost of medical study out of his earnings as first violin at the Opéra Comique. His thesis for the doctorate in 1860 was on the pathogenesis of albuminuria, and in 1863 he published a comparative study of ancient and modern humoralism. In 1864 his work on motor paralyses and ataxias was published and was received with enthusiasm. In 1871 he published his clinical lectures, followed by a treatise on internal pathology, and in 1876 by a dictionary of practical medicine. In 1877 he was appointed a professor of the Paris Faculty of Medicine and in the same year was elected a member of the Academy, where his erudition, his eloquence, and his remarkable memory were greatly appreciated. This exceptional memory enabled him to learn by heart the memorial addresses that he had to deliver in his capacity of permanent secretary of the Academy, surprising his hearers by the accumulation of dates, of proper names, and of quotations. In spite, however, of the admiration he aroused, the somewhat disdainful hauteur with which he judged of certain works was a source of surprise. Careless of popularity, while he took no trouble to gain the esteem of his *confrères* or the admiration of his pupils, he nevertheless secured the respect of all. M. Yvon, a member of the Section of Pharmacy of the Academy of Medicine, was one of the most active personalities and one of the best informed and most courteous of the Parisian scientific world. Besides active collaboration in the preparation and revision of the Codex, an immense work in itself to which he modestly devoted much of his life, he published some notable studies on the preparation of certain drugs, an elaborate monograph upon ergot and its derivatives, and other works.

The Surgical Treatment of Hæmorrhoids.

At the Société des Chirurgiens de Paris on April 11th M. Abel Desjardins said that to ensure a complete cure of hæmorrhoids, whatever operation was employed, it was necessary to remove the entire hæmorrhoidal plexus, to resect the mucosa, which was always affected, and to dilate the sphincter. He could not admit the alleged defects attributed to Whitehead's operation, but regarded them as the results of defective technique. He then described his own method, which had given him excellent results.

Explosion at the Hôpital Laennec.

A serious explosion occurred on April 25th in the laboratory of one of the wards of the Hôpital Laennec, causing great alarm among the patients, many of whom crept under their beds or attempted to escape, while the more helpless ones uttered heartrending cries. The ward attendants finally calmed them and no one was injured, but the laboratory and all its contents were destroyed, and a fire was prevented only by the promptitude of those on duty.

The Prophylaxis and Specific Treatment of Typhoid Fever.

On April 22nd M. Debove presented to the Academy of Medicine a communication by Dr. Petrovitch, in charge of the infectious diseases hospital at Uskub, on the effects of serum therapy and antityphoid inoculation in typhoid fever. Up to the present time antityphoid inoculation has not been used in the Servian troops, but Dr. Petrovitch practised it in the case of persons who were brought especially into contact with typhoid patients. He employed the vaccine in a small dose to avoid the dangers of the negative phase. Beginning with himself, he made 120 injections, using a dose equal to 100 millions of bacilli killed by heat and diluted with a cubic centimetre of physiological serum. Notwithstanding the impossibility of the vaccinated persons removing themselves from the typhoid influence during the period immediately following the inoculation, only two of these persons contracted typhoid fever, and that in a very benign form. They became convalescent, one in 14 days, the other in 20. In the treatment of the disease Dr. Petrovitch used the vaccine employed in the British army, made from Eberth's bacilli killed by heat. An injection of the vaccine diluted with physiological serum, and corresponding to 20,000,000 of Eberth's bacilli, was given in each case in the subclavicular region. The number of typhoid patients admitted to hospital was 680, of whom 460 were submitted to bacteriotherapy. The other 220 patients preferred not to undergo it. Both groups were also treated with cold baths. The number of injections varied between one and three. Excluding those who died within 24 hours of admission, the mortality was 2·9 per cent. of the vaccinated and 12·8 per cent. of those treated exclusively with cold baths, both classes of patients [illegible] ubjected to the same [illegible] among the Servian [illegible] open air and slept in tents or in the open. It was only when the troops had to be lodged in buildings in the conquered towns that the crowding and uncleanliness combined gave rise to epidemics of dysentery and typhoid fever.

April 28th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Medical Department of the Austro-Hungarian Army in Readiness for War.

THE proximity of the countries engaged in the recent war, together with the intimate national and racial relations between a portion of the belligerents and the Austrian Empire, has made it most important for us to be prepared for any and every emergency in the near future. Prominent among such precautions would be the bringing of the medical department of the army into a state of complete readiness for active service, because the experience of all the surgeons, whether of the Red Cross Society or of the volunteer expeditions, who were able to see active service at the front proves the utter inadequacy of all the medical and hygienic preparations made by the belligerents on both sides. The Vienna Gesellschaft der Aerzte has done much to elucidate the real state of affairs by organising a series of lectures and discussions on this subject, mostly delivered by surgeons returning from the battlefield, where they had been working for several weeks. Among the various papers a most able one was read by Professor Hochenegg, the director of the first surgical clinic in the Vienna General Hospital. He summarised the necessary preparations under three heads—namely: (1) medical aid for the sick and wounded soldiers; (2) the nursing staff; and (3) the materials for sanitary purposes. He calculated that, in accordance with the percentage of casualties found in the recent engagements, a minimum of 100,000 wounded men would have to be cared for. The Austrian Red Cross Society had accommodation ready in its hospitals for only 10,000 men, whilst another 50,000 wounded would fall to the care of the Austrian army, the remaining 40,000 being in the care of the Hungarian part of our Empire. These 50,000 would have to be made fit for transport in the field hospitals before being sent to the rear. Assuming that 20 men could be accommodated in one room, 250 hospitals, each having ten rooms (200 beds), would be required for this purpose in the field. Each ward or field hospital ought to have at least one surgeon in charge and two surgically competent assistants. This number of surgeons was not at present provided for in the army, and the reserve of medical officers ought to be distributed amongst the regiments according to this principle. Even worse conditions prevailed as regards the nursing staff. The Red Cross Society had a fairly sufficient staff for its hospitals, but the remaining 50,000 patients would require at least 500 thoroughly trained nurses (2 per hospital) who would be able to work as head nurses, with another 7500 assistant nurses (3 per room of 20 beds, or 30 per hospital). Austria has not so many nurses, and therefore they would have to be sought from those volunteering for that service. Moreover, besides those nurses who would be wanted in the hospitals, a very large number would be required for substitution in other hospitals, whence the regular sisters would be called to the front, also for convalescent homes and for infectious and contagious wards, so that a total of 25,000 nurses would not be far from the actual figure wanted. But the experience of the Austrian surgeons in the Balkan cities, where they have had to deal with voluntary nurses (those who offered their services coming from all classes of the population), was very discouraging. The people whom they had to employ were neither reliable, earnest, nor willing, and the only result was a complete breakdown of the voluntary nursing system. Professor Hochenegg therefore advised a very energetic action in this respect in order to secure the indispensable number of female nurses in case of need. The third point of his paper dealt with the medical requisites for the sick and wounded in a modern war. The amount of dressings only wanted for 50,000 wounded was calculated at about 12,000,000 yards of roller bandages within one month, and all other substances (alcohol, ether, chloroform, ointments, solutions, &c.) would have to be provided for in enormous quantities. For this reason the factories should be bound by contracts to keep always a stock ready for immediate delivery sufficient at least for four weeks. It has happened several times that factories have been sold out for days owing to the demands upon their resources during the Balkan war. It was also important to be prepared for outbreaks of war-borne epidemics such as cholera, dysentery, typhoid fever, smallpox, tetanus, and the like. Large stocks of vaccines and serum should always be at hand in the State laboratories, and a well-equipped corps should be organised for the purpose of dealing with such an outbreak, either at the front or in the rear of the army. Prompted by the interesting paper read before the society, Dr. Steiner, the principal staff surgeon of the Austrian Military Medical Corps, stated at once what preparations the army authorities had already made to meet any emergency. First of all, he said, the army was prepared to provide more than double the number of beds mentioned in the paper, and a large number of soldiers were fully trained as nurses. The stocks of medical requisites were also amply sufficient and were being constantly replenished, as well as kept up to date by very frequent inspections. Indiarubber goods were the only articles kept in stock to a limited extent, because they soon became deteriorated if not frequently used, but contracts had been made providing for immediate delivery of a sufficiency of this class of requisite on a day's notice being given to the factories. The army authorities, however, viewed with some anxiety the difficulty of procuring a sufficiently numerous and adequately trained female nursing staff, and would encourage in every way the efforts of the Austrian Red Cross Society to induce females of the better classes to take up the profession of trained nurses. For this purpose it was important to increase the number of the members. Whilst Japan had more than 2,000,000 members of the Red Cross Society (5 per cent. of the population) and Germany had 600,000 (1 per cent. of the population), we had hardly 60,000 (0·2 per cent. of the population).

The Sale of Pathogenic Micro-organisms.

The recent criminal case at Frankfort, in which a man tried to kill his wife by injecting her with pathogenic bacteria, has brought to the notice of the public and the authorities how easy it is to obtain virulent substances convenient for secret administration with felonious intent. The sero-therapeutic institute in Vienna, where the famous "Kral Museum" is situated, contains stocks of nearly all the organisms known to science. It used to provide bacteria only for scientific institutes, but the present case has shown that all the care which might have been expected has not been taken, for the would-be murderer bought his bacteria by pretending to be the owner of a chemical laboratory. In consequence of this criminal attempt strict precautions have now been adopted, so that in future such dangerous objects as pathogenic bacteria will not be supplied to any person who may make an improper use of them. None but officially recognised institutes and medical men of acknowledged scientific standing will be able to procure them from Vienna.

April 28th.

CANADA.

(From our own Correspondent.)

Dominion Registration.

The next meeting of the Medical Council of Canada will be held at Ottawa on June 17th and four following days. It is expected that by that time the Council will be in a position to open the new Register to all those who have been in active practice in Canada for ten years prior to Nov. 7th, 1912, the date on which the Canada Medical Act came into force.

Annual Meeting of the Canadian Medical Association.

The annual meeting of the Canadian Medical Association will be held in London, Ontario, on June 24th, 25th, 26th, and 27th, under the presidency of Dr. Hugh A. Macallum, Dr. W. W. Francis, of Montreal, being the general secretary. The programme for the first two days will be devoted to the sections in medicine, surgery, gynæcology, obstetrics, pathology, public health, eye, ear, nose and throat, and X rays. On the morning of the first day Professor McPhedran, of Toronto University, will open a discussion on diseases of the stomach, and Dr. C. F. Martin, of Montreal, Dr. Charles R. Stockton, of Buffalo, U.S.A., Dr. C. D. Aaron, of Detroit, U.S.A., and Mr. H. J. Paterson, F.R.C.S., of London, England, with others will take part. The address in medicine will be delivered by Dr. Llewellys Barker, of Baltimore; that in surgery by Dr. Alex. Hutchison, of Montreal; and that in gynæcology by Dr. Thomas Cullen, of Baltimore. There is to be a symposium on the thyroid gland, introduced by Dr. A. J. Oschner, of Chicago. Dr. Frank Billings, of Chicago, will conduct a medical clinic, and Dr. J. B. Murphy, of Chicago, will give a lantern demonstration on surgical diseases of the bones and joints.

Dr. Friedmann's Visit to Canada.

h Dr. Friedmann came to Canada from New York,
eously received by the Canadian medical pro-
treated patients in Montreal, Ottawa, Toronto,
He was invited to Toronto by the University,
some criticism of the University for inviting
a secret remedy. Not a single cure has
ate, but the profession in Canada are
, with a disposition to wait patiently
e, the lay press found Dr. Friedmann's
a newspaper standpoint. The pro-
in the United States and Canada, is wondering why Dr. Friedmann passed by England and France to demonstrate his "cure" on this side the Atlantic.

Canadian Association for the Prevention of Tuberculosis.

At the annual meeting of this association, held in Ottawa on March 12th and 13th, over 150 medical men were present from different points in Canada, as well as a number of lay delegates. The Hon. Adam Beck, London, Ontario, presided, and the meeting was graced by the presence of H.R.H. the Duke of Connaught, who has always manifested great interest in the work of the association. Dr. Friedmann was present, and read a paper on his "cure."

Cocaine in Canada.

The Academy of Medicine, Toronto, and the Montreal Medico-Chirurgical Society have recently passed resolutions calling the attention of the Federal Government to the importation into Canada of a certain asthma remedy which contains a considerable amount of cocaine. They urge that if it be allowed to enter Canada at all it should be obtainable by the public only on the prescription of a local registered practitioner.

Vancouver General Hospital.

The city of Vancouver recently voted $375,000 for extending the work of this hospital. A nurses' home is to be built, two units of an isolation hospital, and a service building. A new wing was added last year, and when this is finally completed and furnished there will be accommodation in the main building of the institution for 375 beds. During the past year 377 deaths occurred in the institution, the number of patients treated being 5231. The daily cost per patient was $1.98. The hospital is in debt to the amount of $42,000.

April 15th.

THE NATIONAL INSURANCE ACT.

London Insurance Committee.

At the meeting of the London Insurance Committee on April 24th the medical benefit subcommittee recommended the extension of the medical ticket until July 14th in order that the medical register might be completed and insured persons given a further opportunity of selecting their doctors. On this report there was an attempt to initiate a debate on a proposal to limit the number of persons who might be accepted by one person. The chairman, however, ruled that a matter of such importance could not be raised without notice, and the report was thereupon adopted.

Acceptance of a Limited Number of Patients.

The subcommittee also reported that it had had under consideration representations from medical men who expressed willingness to join the panel if they were permitted to limit the total number of persons whose treatment they were expected to undertake. It appeared that the extent of the private practices of a number of medical men was a bar to their unconditional consent to join the panel. In this connexion the subcommittee quoted an answer given in the House of Commons on Feb. 14th by the Financial Secretary to the Treasury to the effect that if an Insurance Committee allowed doctors to accept a limited number of lives these must be an "average sample" of lives, and the approval of other doctors on the panel must be obtained. The subcommittee understood that the suggested limitation would enable a large number of medical practitioners to join the panel. The Insurance Commissioners had stated that there would be no necessity to include names of medical practitioners in the lists of doctors supplied for use in each metropolitan borough, provided that their names were included in the alphabetical list for the whole county, and this list was publicly exhibited. The medical practitioners on the panel had already agreed to a proposal to allow a doctor to limit the number of insured persons accepted by him. The subcommittee recommended that doctors be permitted to join the panel for the purpose of treating a limited number of persons, and this was approved.

Complaint against a Medical Practitioner.

At the meeting of the Committee held on April 3rd the medical service subcommittee presented a report that a complaint had been made regarding a medical practitioner on the panel that when asked to attend a patient he said he wanted "live men, not dying ones" The doctor denied absolutely the whole of the circumstances but the *subcommittee, after careful inquiry, reported that it was satisfied that the state*ments made by the complainant were correct A recommendation that a copy of the report be forwarded to the practitioner was referred back to the subcommittee on the ground that more stringent action should be taken The matter came before the Committee again on April 24th It was pointed out by Mr R C K Ensor that under the Regulations the Committee had no middle course between the extreme measure of reporting to the Commissioners with a view to removal of the doctor from the panel, and doing nothing at all Mr E B Turner asked if it was not possible for the Committee to do something more definite than a vote of censure Mr O E Warburg, the chairman of the subcommittee, remarked that the punishment in this case was not contained in the fact that a transference of the patient to another medical man was proposed, that was merely incidental The subcommittee felt that in conveying to the doctor, on the authority of the Insurance Committee, that after hearing his evidence in full the Committee had come to the conclusion he was not speaking the truth, a penalty of some severity was being inflicted This expression of opinion would be on record, and it was *tantamount to a reprimand*

The Committee approved the action taken by the subcommittee

MANCHESTER MEDICAL COMMITTEE

The Manchester Medical Committee was elected at a meeting, to which every medical practitioner in the city was invited, *on Feb 8th, 1913* *The composition of the com*mittee was decided upon as follows (1) eight representatives *from each district—North South West, and Central*, (2) all medical practitioners appointed to the Manchester Insurance Committee, (3) two representatives of the medical women of Manchester

The Manchester Medical Committee consists of Dr T A Helme (chairman) Dr C G L Skinner and Dr A W Chapman (vice chairmen) Dr J D'Ewart (honorary treasurer), Dr R G McGowan, 1 Thomas street, Cheetham Hill and Dr A E Cotterill, 42 Brook road, Fallowfield (honorary secretaries) together with 32 *other members* The medical representatives on the Manchester Insurance Committee elected by the local medical profession are Dr T A Helme and Dr R G McGowan, those appointed by the Manchester city council are Dr A W Chapman and Dr J Stavely Dick, those appointed by the Insurance Commissioners are Dr E Johnstone and Dr E M Brockbank The members of the profession on the Medical Service Subcommittee are Dr T A Helme, Dr C G L Skinner, and Dr A E Cotterill

The following is the scale of fees agreed upon between the Manchester Medical Committee and the Manchester Insurance Committee —

		£	s	d
1	*Attendance on the patient at the practitioner s residence* surgery, or dispensary	0	2	0
2	Visit to the patient s residence	0	2	6
3	Special visit—i e a visit paid the same day *in response to a call received* after 10 A M	0	3	6
4	Night visit—i e a visit made between the hours of 9 P M and 9 A M *in response to a call received* between those hours	0	5	0
5	Surgical operation requiring local anæsthesia (other than incision of abscess)	0	10	6
6	Cases of abortion and miscarriage to be treated at ordinary rates			
7	Administration of a general anæsthetic	1	1	0
8	Setting of fracture or reduction of dislocation	0	10	6
9	Sanatorium benefit report Med 2 Ordinary fees for succeeding visits or consultations	0	5	0

The Manchester Medical Committee having been asked whether certain procedures requiring a local anæsthetic are to be entered as operations under Section 5 of the above scale, a subcommittee has the question of further definition under consideration, and possibly it may be found desirable to arrange for a revised scale with a schedule dividing the operations commonly *undertaken in* general *practice* under local anæsthesia into groups at different fees In the meantime the Committee advises practitioners to follow as closely as possible the lines of ordinary practice, and book as operations under local anæsthesia only such procedures as have hitherto been usually charged at the rate of *7s 6d* or more in addition to the ordinary visiting or consultation fee

Wessely, extraordinary professor of ophthalmology, has been promoted to the chair of that subject in succession to Dr. von Hess.

CENTRAL MIDWIVES BOARD.—A meeting of the Central Midwives Board was held at Caxton House, Westminster, on April 17th, with Sir Francis H. Champneys in the chair. A letter was considered from the town clerk of Birmingham with regard to the effect of the National Insurance Act on the work and future training of midwives. The Board directed that the town clerk of Birmingham be informed (*a*) that the question does not come within the scope of the duties of the Board, and (*b*) that the correspondence be forwarded to the Privy Council. A letter was considered from the Clerk of the Flintshire county council suggesting that the Board should adopt "a simpler form of case book ...... for the use of nurses." The Board directed that the clerk of the Flintshire county council be informed that the Board sympathises with the difficulty of the Flintshire county council, but the register has been carefully thought out, and it is hoped that the education of the midwives may so greatly improve as to render any alteration of it unnecessary. A letter was considered from the clerk of the Middlesex county council inquiring as to the extent to which "approved" midwives should themselves attend with their pupils (*a*) at the time of the confinement, and (*b*) during the lying-in period. The Board directed that the clerk of the Middlesex county council be informed that the Board holds each "approved" midwife directly responsible for the cases attended and for any neglect in supervising the training of pupils, but it does not specify the number of visits which must be paid, as this must vary greatly in different cases.—A special meeting of the Central Midwives Board was held on April 24th at Caxton House, Westminster, with Sir Francis H. Champneys in the chair. The Board considered the following charges amongst others against the midwives whose names are given below, and ordered them to be struck off the roll:—Emma Dickson, that being in attendance as a midwife at a confinement, the patient suffering from serious rupture of the perineum, she did not explain that the case was one in which the attendance of a registered medical practitioner was required, nor did she hand to the husband or the nearest relative or friend present the form of sending for medical help, properly filled up and signed by her, in order that this might be immediately forwarded to the medical practitioner, as required by Rule E.20 (3); she attended the patient for eight days only, following the confinement; she discontinued her attendance at a time when the patient was seriously ill; and she did not at any time take the pulse or temperature of the patient, as required by Rule E. 13. Anna Hobbs, that being in attendance as a midwife at a confinement she paid only two visits to the patient; she neglected to take the patient's pulse or temperature, as required by Rule E. 13; she was not of sober habits; and she neglected to attend her patients with regularity and to pay an adequate number of visits. Nancy Sheldon, that being in attendance as a midwife at a confinement, the patient suffering from retained placenta, she endeavoured to secure its expulsion by traction on the cord, and a registered medical practitioner having been sent for she failed to notify the local supervising authority thereof, as required by Rule E. 21 (1). Esther Tiley, that being in attendance as a midwife at a confinement she endeavoured to assist delivery of the placenta by traction on the cord; she omitted to record in her register of cases the occurrence of any complication; and that she was unable to make use of a clinical thermometer, and consequently could not comply with Rule E. 13. Elizabeth Anne Wood, that being in attendance as a midwife at a confinement, the child suffering from inflammation of, and discharge from the eyes, she did not explain that the case was one in which the attendance of a registered medical practitioner was required, nor did she hand to the husband or the nearest relative or friend present the form of sending for medical help, properly filled up and signed by her, in order that this might be immediately forwarded to the medical practitioner, as required by Rule E. 20 (5). Th following midwives were cautioned after charges again them had been considered: Emma Josephine Chapma Lydia Edwards, and Edith Elizabeth Tripp.

THE Royal Dental Hospital, Leicester-squar has received a donation of £100 from Mr. John Lewi executor of the will of the late Miss Ames.

NURSING AND MIDWIFERY CONFERENCE.—Th sixth annual conference was held last week at the Hort cultural Hall, Westminster, when many subjects of interes were discussed, and the speakers included a number c medical men as well as nurses. Vaccine and the Tubercul Treatment of Consumption were dealt with by Dr. W. d'Est Emery and Dr. Halliday G. Sutherland. Poor-law Nursing wa dealt with by Miss Gibson, who pointed out the defects an suggested a central organisation by means of which the larg unions could help the smaller ones; and by Miss Elma Smit who gave an interesting account of some of the reforms whic she had seen introduced during the last 20 years. In th Massage Session the principal speakers included Dr. J. S Mackintosh and Dr. R. W. A. Salmond. The last tw days were devoted to social work, finance, and nursing abroa In the Midwifery Sessions many subjects of technical an professional interest were discussed. Dr. W. Douglas Knocke barrister-at-law, traced the history of midwifery in Englan from the early Middle Ages down to the last century. Re ferring to Clause 1 (2) of the Midwives Act, he said it mu be remembered that uncertified practice was forbidde "habitually *and* for gain," not "*or* for gain." This enable a woman to practise for charity, or occasionally for gai Several speakers dealt with the question of training in i various aspects, and all agreed that a longer training wa necessary. Miss Alice Gregory and Miss Mona Wilso discussed the maternity benefit and midwives under th National Insurance Act, and Mrs. Stephen Glanville calle attention to the professional outlook for midwives, whic would be either improved or destroyed by the Act In his address on Infant Feeding in Midwifery Practice, Dr Eric Pritchard brought forward several interesting points He insisted on the inability of the child's stomach at birt to assimilate food and the necessity of the development o the power of digestion along the lines of nature. All foreig matter was poisonous to the child's stomach and interfere with the development of the power of digestion. Even the colostrum of a wet nurse was foreign matter because th colostrum of one woman differed from that of another He urged the plan of training an infant from the first to tak a certain amount of food at absolutely regular intervals. H recommended three hours as a suitable interval. In German four-hour intervals had been adopted with success, but in vestigation seemed to show that English mothers did no secrete as much milk as German mothers. He had foun the cheapest artificial food which could be given to an infan was dried separated milk, with the addition of linseed oil i order to supply the necessary fat. Mr. Bishop Harma gave a lecture on Ophthalmia, with epidiascopic illustra tions, and Dr. J. S. Fairbairn addressed the midwives o their Duties and Dangers in Connexion with Venere Disease.

ROYAL MEDICAL BENEVOLENT FUND.—At th April meeting 21 cases were considered and grants amoun ing to £200 voted to 18 of the applicants. Appended is a abstract of the cases relieved:—

Widow, aged 57, of L.R.C.P. Edin. Only income about 10s. a wee from lodgers; children unable to help. Relieved three times, £3 Voted £10.—Widow, aged 51, of M.B., C.M. Glasg. Since husband death ten years ago has been supported by a son, but asks for a litt help to relieve him. Voted £5.—Daughter, aged 45, of late M.R.C [illegible] her post owing [illegible] oms Relie [illegible] L.R.C.S. Edi [illegible] illness, and [illegible] grave internal complaint. No income. Thr children, the eldest only 16. Voted £24.—Widow, aged 48, L.R.C.P., L.R.C.S. Edin. Health too feeble to admit of occupation. an is allowed £1 a mon [illegible] Ladies' Guild. Is a candida for a pension from t [illegible] ospital for Incurables. O child dependent a [illegible] to help. Relieved 17 time £196. Voted £12.—Widow, aged 43, of M.B., C.M. Aberd. Supplemen an income of a few shillings a week by taking boarders, but having fo young children finds great difficulty in meeting her unavoidab expenses. Relieved twice, £20. Voted £10.—Daughter, aged of late M.R.C.S. Is mentally feeble, and for many yea has been practically dependent on this Fund and a small pe sion given by another society. Relieved 14 times, £144. Voted £12.

Daughter, aged 42, of late L.R.C.P., L.R.C.S. Edin. Endeavours to [illegible]

[illegible] years from a spinal complaint, and is now practically bedridden. [illegible]

[illegible] boarding-house. [illegible] ster who can ill afford to help.

Contributions may be sent to the honorary treasurer, Dr. Samuel West, 15, Wimpole-street, London, W.

DONATIONS AND BEQUESTS.—By the will of the late Mr. Edward Webb, of Studley Court, Stourbridge, the testator left £5000 to the Corbett Hospital, Amblecote, Staffs; £3000 for or towards a wing to be called the Margaret Jane Webb Wing in memory of his wife, and £2000 for the furnishing and equipment of that wing.—The late Colonel Frank Shuttleworth, of Old Warden Park, Biggleswade, has left by will £3000 to the Bedford County Hospital, £2000 to the Lincoln County Hospital, £1000 each to the Middlesex Hospital and the Cancer Hospital, Brompton; and £500 each to the Great Northern Central Hospital, the Bedford Dispensary, and the Lincoln Dispensary.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Sale of Inflammable Fabrics.

MR. THEODORE TAYLOR, in introducing the Misdescription of Fabrics Bill in the House of Commons on Wednesday, April 23rd, announced *that its sole object is to prevent the sellers of textile fabrics from* describing as inflammable articles which are not so. The measure has been brought forward with a desire to lessen the number of burning fatalities which arise from flannelette clothing catching fire. The extent of this evil was revealed in the report of the Departmental Coroners Committee, which in 1910 recommended legislation to make it penal to describe as "safe," flannelette or other textile fabrics which were highly inflammable. The Bill does not prohibit the sale of these fabrics, nor does it require them to be marked "dangerous" It merely prohibits them being marked or represented as "safe against fire." The Bill was read a first time. Its backers include Dr. ADDISON, Mr. BOLAND, Colonel BROCKLEHURST, Sir FREDERICK CAWLEY, Sir HENRY CRAIK, Mr. FERENS, Mr. HILLS, Mr. JOYNSON-HICKS, Sir JOHN MCCALLUM, Mr. NUTTALL, and Mr. ALBERT SMITH.

Nurses' Registration Bill.

A deputation organised by the Central Committee for the State Registration of Trained Nurses, and introduced by Dr. CHAPPLE, M.P., was received by Mr. ASQUITH on Monday, April 23th. The Prime Minister, in answer to requests to give Government time for the passage of the Nurses' Registration Bill, declined to grant special facilities, but suggested that the supporters and opponents of the measure should confer *in order to see whether an approach to* unanimity could be reached.

Amongst those present were Mr. MUNRO FERGUSON, M.P., and Lady HELEN MUNRO FERGUSON, Dr. CHAPPLE, and the following delegates from affiliated societies:—The British Medical Association: Sir Victor Horsley, F.R.S.; Dr. Alfred Cox, medical secretary. The Matrons' Council of Great Britain and Ireland: Miss L. V. Haughton, matron, Guy's Hospital, London; Miss R. Cox Davies, matron, Royal Free Hospital, London. The Royal British Nurses' Association: Dr. Comyns Berkeley, medical honorary secretary; Miss E. C. Tawney. The Society for the State Registration of Trained Nurses: Mrs. Bedford Fenwick, President; Miss Margaret Breay, honorary secretary. The Fever Nurses' Association: Dr. E. W. Goodall, Past President, Medical Superintendent, Eastern Fever Hospital; Dr. Biernacki, medical superintendent, Plaistow Fever Hospital. The Association for Promoting the Registration of Nurses in Scotland: Dr. D. J. Mackintosh, M.V.O., honorary secretary. The Scottish Nurses' Association. Dr. J. McGregor Robertson, Vice-President; Miss M. Dow, honorary treasurer. The Irish Nurses' Association. Miss M. Huxley, President. Miss Alice Reeves, matron, Royal Eye and Ear Hospital, Dublin. The National Council of Trained Nurses of Great Britain and Ireland Miss E. M. Musson, Vice-President, Matron, General Hospital, Birmingham; Miss E. C. Barton, matron, Chelsea Poor-law Infirmary. The National Union of Women Workers of Great Britain and Ireland: Miss Agnes Garrett.

HOUSE OF COMMONS.

WEDNESDAY, APRIL 23RD.

Insured Persons in Hospitals.

Mr. WORTHINGTON EVANS asked the Secretary to the Treasury whether in the case of an insured person without dependents having to pay 5s. a week for her maintenance in the Nelson Hospital during a time when she was otherwise qualified for sick benefit, the fact that she was in a hospital prevented her society paying her sick benefit [illegible] benefit of the insured person

years from a spinal complaint, and is now practically bedridden.

boarding-house. ster who can ill afford to help.

Contributions may be sent to the honorary treasurer, Dr. Samuel West, 15, Wimpole-street, London, W.

DONATIONS AND BEQUESTS.—By the will of the late Mr. Edward Webb, of Studley Court, Stourbridge, the testator left £5000 to the Corbett Hospital, Amblecote, Staffs; £3000 for or towards a wing to be called the Margaret Jane Webb Wing in memory of his wife, and £2000 for the furnishing and equipment of that wing.—The late Colonel Frank Shuttleworth, of Old Warden Park, Biggleswade, has left by will £3000 to the Bedford County Hospital, £2000 to the Lincoln County Hospital, £1000 each to the Middlesex Hospital and the Cancer Hospital, Brompton; and £500 each to the Great Northern Central Hospital, the Bedford Dispensary, and the Lincoln Dispensary.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Sale of Inflammable Fabrics.

Mr. THEODORE TAYLOR, in introducing the Misdescription of Fabrics Bill in the House of Commons on Wednesday, April 23rd, announced *that its sole object is to prevent the sellers of textile fabrics from* describing as inflammable articles which are not so. The measure has been brought forward with a desire to lessen the number of burning fatalities which arise from flannelette clothing catching fire. The extent of this evil was revealed in the report of the Departmental Coroners Committee, which in 1910 recommended legislation to make it penal to describe as "safe," flannelette or other textile fabrics which were highly inflammable. The Bill does not prohibit the sale of these fabrics, nor does it require them to be marked "dangerous" It merely prohibits them being marked or represented as "safe against fire." The Bill was read a first time. Its backers include Dr. ADDISON, Mr. BOLAND, Colonel BROCKLEHURST, Sir FREDERICK CAWLEY, Sir HENRY CRAIK, Mr. FERENS, Mr. HILLS, Mr. JOYNSON-HICKS, Sir JOHN McCALLUM, Mr. NUTTALL, and Mr. ALBERT SMITH.

Nurses' Registration Bill.

A deputation organised by the Central Committee for the State Registration of Trained Nurses, and introduced by Dr. CHAPPLE, M.P., was received by Mr. ASQUITH on Monday, April 23th. The Prime Minister, in answer to requests to give Government time for the passage of the Nurses' Registration Bill, declined to grant special facilities, but suggested that the supporters and opponents of the measure should confer *in order to see whether an approach to* unanimity could be reached.

Amongst those present were Mr. MUNRO FERGUSON, M.P., and Lady HELEN MUNRO FERGUSON, Dr. CHAPPLE, and the following delegates from affiliated societies:—The British Medical Association: Sir Victor Horsley, F.R.S.; Dr. Alfred Cox, medical secretary. The Matrons' Council of Great Britain and Ireland: Miss L. V. Haughton, matron, Guy's Hospital, London; Miss R. Cox Davies, matron, Royal Free Hospital, London. The Royal British Nurses' Association: Dr. Comyns Berkeley, medical honorary secretary; Miss E. C. Tawney. The Society for the State Registration of Trained Nurses: Mrs. Bedford Fenwick, President; Miss Margaret Breay, honorary secretary. The Fever Nurses' Association: Dr. E. W. Goodall, Past President, Medical Superintendent, Eastern Fever Hospital; Dr. Biernacki, medical superintendent, Plaistow Fever Hospital. The Association for Promoting the Registration of Nurses in Scotland: Dr. D. J. Mackintosh, M.V.O., honorary secretary. The Scottish Nurses' Association. Dr. J. McGregor Robertson, Vice-President; Miss M. Dow, honorary treasurer. The Irish Nurses' Association. Miss M. Huxley, President. Miss Alice Reeves, matron, Royal Eye and Ear Hospital, Dublin. Notes, Short Comments, and Answers to Correspondents.

PUBLIC HEALTH AT KINGSTON, JAMAICA, IN 1911

THE capital of Jamaica had a population in 1911 of 57 379, with a birth rate of 36 28 and a death rate of 29 47 per 1000, the latter was lower than in any year since 1907 when the occurrence of an earthquake was followed by a considerable increase in mortality Year by year since then (except in 1910) there has been a progressive reduction During the year under review there was no outbreak of any serious disease though the endemic of typhoid fever that started after the earthquake in 1907 still continued, there were 190 cases of which 147 were resident in Kingston No decided opinion appears to have been arrived at as to its causation except a suggestion as to " the enormous importance of the personal over any other factor in the spread of the disease Allusion is also made to a connexion between a foul privy system and enteric incidence, and to possible spread through the mediation of flies The three preventive measures required are extension of the sewerage system improvement in domestic sanitation, and control of typhoid cases and carriers Malaria has been much less prevalent and severe than in any recent year largely on account of the energetic antimosquito measures adopted All known breeding grounds are regularly treated and it is hoped that in a year or two all possible breeding grounds will be abolished Not a single case of yellow fever has been reported Stegomyia fasciata is to be found in about 4 per cent of the rooms and yards visited, but is becoming scarcer year by year There has been no plague, but rat destruction is carried out by means of virus, and in view of the approaching opening of the Panama Canal vigilance will be required Tuberculosis has caused a mortality of 2 8 per 1000, this is a lower rate than in any year since that *of the earthquake (1907) when there was a sudden and considerable* increase of deaths from this cause Pulmonary tuberculosis is now a compulsorily notifiable disease in Kingston and though no special means of isolation have been available, much good work has been done in the way of disinfection and by informing public opinion generally as to preventive measures As the medical officer of health, Dr Angus Macdonald, says in his introductory letter, there is nothing extraordinary to be related in the public health affairs of Kingston during the year, but this absence of any particular matter requiring comment is itself a matter for congratulation, as indicating the efficacy of the preventive measures that have been carried out

RESULTS OF VACCINATION IN THE PHILIPPINE ISLANDS

THE report of the Director of Health, Dr Victor G Heiser, for the last quarter of 1912 shows clearly the value of vaccination as a preventive of small pox The Philippines and particularly Manila had continuously been endemically subject to small pox in an excessive degree until the United States undertook the task of wholesale vaccination on its occupation of the islands The first result was a complete stamping out of an epidemic in Manila The extension of *wholesale vaccination to the Archipelago was of* course, a much larger matter, but from the present report we learn that encouraging progress has been made, and that " there have been fewer cases of small pox in the Philippines than at any time for which records are available , Moreover, " the control of this disease which was achieved in the more settled sections of the Philippines has been maintained and in Manila, for instance, there has not been a single death from small pox since June 15th, 1909

THE BAHREIN ISLANDS

REPORTING on these islands, the largest group in the Persian Gulf, under the protectorate of the Indian Government, Captain D L R Lorimer, Political Agent, states that almost the entire population, estimated at 100,000, is Mahommedan and the immense majority of the people are Arabs In Manama, the capital, however, there is a strong contingent of foreign non Arabs, these consisting of two or three Europeans, a few American missionaries, a few score Hindus, a large body of Persians, and some Jews The climate of Bahrein, the largest of the group of islands, is extremely damp at all seasons, and is undoubtedly unhealthy The extremes of heat and cold are not excessive, but the extreme moisture makes even moderate heat disagreeable There is a great deal of very strong north west wind, varied in the later hot weather by spells with a south-east wind or no wind, when the damp is so great that the dry and wet bulb thermometers show as little as 2° difference at a temperature of between 95° and 100° F Hot weather conditions prevail from the beginning of May well on into October The *barah*, or 40 days *shamal*, which is expected in June and July, often makes the climate at that time comfortably cool and pleasant The rainfall is light, but has been showing a tendency to increase in recent years The average in the ten years 1902-11 was 2·069 inches, whilst in

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced:—

April 26th–Nov. 5th (Ghent).—International Exhibition.
May 5th–8th (London, Caxton Hall).—Parents' National Educational Union, Seventeenth Annual Conference.
" 5th–8th (Paris).—Congress of the French Ophthalmological Society.
" 6th–8th (Washington).—Tenth Annual Meeting of the American Society of Tropical Medicine.
" 14th–17th (Halle a-S.)—Fifteenth Meeting of the German Gynæcological Society.
" 15th–18th (Paris).—Twenty-first Annual Congress of the Royal Institute of Public Health.
May [illegible]
" [illegible]
June [illegible]
" [illegible]
" 24th–27th (London, Ontario).—Canadian Medical Association.
" 30th and July 1st (London, Guildhall).—Conference on Diet, Cookery, and Hygiene in Elementary Schools and Institutions.
July 7th–12th (Exeter).—Twenty-eighth Congress of the Royal Sanitary Institute.
" 16th–18th (Oxford, Keble College).—Oxford Ophthalmological Congress.
" 21st–24th (London).—British Pharmaceutical Conference.
" 22nd–25th (Brighton).—Eighty-first Annual Meeting of the British Medical Association.
Aug. 1st–3rd (Ghent).—Congress against the Adulteration and Deterioration of Foodstuffs.
" 1st–5th (Brussels).—Third International Conference on Cancer.
" 4th and 5th (London, Caxton Hall).—English-speaking Conference on Infant Mortality.
" 6th–12th.—(London).—Seventeenth International Congress of Medicine.
" 20th–26th (Ghent).—Third International Congress of Neurology and Psychiatry.
" 25th–30th (Buffalo).—Fourth International Congress of School Hygiene.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—MESSRS. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced:—

April 26th–Nov. 5th (Ghent).—International Exhibition.

May 5th–8th (London, Caxton Hall).—Parents' National Educational Union, Seventeenth Annual Conference.

„ 5th–8th (Paris).—Congress of the French Ophthalmological Society.

„ 6th–8th (Washington).—Tenth Annual Meeting of the American Society of Tropical Medicine.

„ 14th–17th (Halle a-S.)—Fifteenth Meeting of the German Gynæcological Society.

„ 15th–18th (Paris).—Twenty-first Annual Congress of the Royal Institute of Public Health.

May [illegible]

„ [illegible]

June [illegible]

„ [illegible]

„ 24th–27th (London, Ontario).—Canadian Medical Association.

„ 30th and July 1st (London, Guildhall).—Conference on Diet, Cookery, and Hygiene in Elementary Schools and Institutions.

July 7th–12th (Exeter).—Twenty-eighth Congress of the Royal Sanitary Institute.

„ 16th–18th (Oxford, Keble College).—Oxford Ophthalmological Congress.

„ 21st–24th (London).—British Pharmaceutical Conference.

„ 22nd–25th (Brighton).—Eighty-first Annual Meeting of the British Medical Association.

Aug. 1st–3rd (Ghent).—Congress against the Adulteration and Deterioration of Foodstuffs.

„ 1st–5th (Brussels).—Third International Conference on Cancer.

„ 4th and 5th (London, Caxton Hall).—English-speaking Conference on Infant Mortality.

„ 6th–12th.—(London).—Seventeenth International Congress of Medicine.

„ 20th–26th (Ghent).—Third International Congress of Neurology and Psychiatry.

„ 25th–30th (Buffalo).—Fourth International Congress of School Hygiene.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—MESSRS. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

THE LANCET Office, April 30th, 1913.

The f[illegible] been received:—Jou[illegible] Revue d'Hygiène, Arc[illegible] ynäkologie, Indian Ambulance Gazette, Transvaal Medical Journal, British Review, Schmidt's Jahrbücher, Journal of Physiology, Journal of Obstetrics and Gynæcology of the British Empire, Vita Sanitaria, Journal of Nervous and Mental Disease, Post Graduate, Archives of Internal Medicine, Homœopathic Recorder, Qui Sait, Bulletins et Mémoires de la Société Médicale des Hôpitaux de Paris.

water were prepared in strengths varying from 1 in 20 to 1 in 100. 0·25 c.c. of the serum was mixed with 0·25 c.c. of the acid solutions and the strength of the acid solution required to neutralise the equal volume of serum was ascertained, a standardised solution of litmus being used as the indicator. Wright's observations have shown that in a normal individual who is not pregnant the strength of the acid solution required to neutralise the serum is between 1 in 30 and 1 in 45, the average being 1 in 35. This may be expressed by the formula :—

$$\frac{N}{35} H_2SO_4$$

I first made a series of observations upon six pregnant women who had shown no signs of deviation from the normal. All the patients were between the thirty-second and fortieth weeks of pregnancy. The results of these observations were as follows :—

Case 1	32 weeks	$\frac{N}{38} H_2SO_4$
„ 2	34 „	$\frac{N}{40}$ „
„ 3	35 „	$\frac{N}{39}$ „
„ 4	38 „	$\frac{N}{37}$ „
„ 5	38 „	$\frac{N}{42}$ „
„ 6	40 „	$\frac{N}{40}$ „

Three observations were taken in each case and the formula given is the mean of the three observations. Comparing these figures with those obtained by Wright it appears that normally there is a slight diminution in the alkalinity of the blood during pregnancy. In the cases of pregnancy toxæmia, however, the fall is generally marked and sometimes very striking. This is shown in the following table :—

Case 1	Eclampsia (after two fits)	$\frac{N}{68} H_2SO_4$
„ 2	*Kidney of pregnancy*	$\frac{N}{54}$ „
„ 3	Eclampsia (before fits)	$\frac{N}{70}$ „
„ 4	Eclampsia (before fits)	$\frac{N}{48}$ „
„ 5	Eclampsia (after seven fits)	$\frac{N}{72}$ „
„ 6	Kidney of pregnancy	$\frac{N}{84}$ „
„ 7	Kidney of pregnancy	$\frac{N}{62}$ „
„ 8	Eclampsia (after one fit)	$\frac{N}{72}$ „
„ 9	Eclampsia (before fits)	$\frac{N}{88}$ „

It will be seen that in all these cases the alkalinity of the blood was below that of normal pregnancy, but the fall in alkalinity bore no definite relation to the severity of the toxæmia, for in Case 9, a relatively mild case, the fall was greatest, whilst in Case 5 in which after many violent convulsions the patient died in coma the fall was much less marked. I h[illegible] only four cases of [illegible] In each instance [illegible] casts and œdema was a marked symptom :—

Case 1	Gravida	36 weeks	$\frac{N}{40} H_2SO_4$
„ 2	„	35 „	$\frac{N}{42}$ „
„ 3	„	30 „	$\frac{N}{38}$ „
„ 4	„	38 „	$\frac{N}{40}$ „

None of these cases had, or subsequently developed, uræmic convulsions. It will be seen that the fall in alkalinity was not greater than that found in normal pregnancy.

Criticism of these results.—In employing this method we cannot claim to estimate accurately the alkalinity of the blood, but having established a normal standard we can detect deviations from that standard, and this is all that is required for the purpose we have in view. Whether we are justified in regarding the diminished alkalinity of the blood as evidence of acidosis in these cases is another question altogether, for in eclampsia lactic acid can often be found in the blood, and it is quite possible that the fall of alkalinity is due in part at least to this cause. Lactic acid may be found after any violent muscular exertion, particularly if the supply of oxygen is deficient and has been detected in considerable quantities after the convulsions of uræmia; I have had no opportunity of examining the blood of a pregnant woman after uræmic convulsions. It must be borne in mind that in acidosis induced by the administration of mineral acids it is some time before the alkalinity of the blood is diminished, for the alkalies are extracted first from the tissues and from the blood only when the supply begins to fail, hence a diminished alkalinity is not to be looked for as an early sign of acidosis, and I have not found it in the slighter cases of toxæmia.

I feel justified, however, in concluding that in cases of albuminuria of doubtful origin in pregnancy the determination of the alkalinity of the blood should form part of the investigation and sometimes affords considerable help in reaching a diagnosis.

The Proportion of Nitrogen Excreted in the Form of Ammonia Salts.

In these series of observations I am greatly indebted to Dr. Priestley and Mr. Mackenzie Wallis, who have performed a considerable number of the estimations. The total nitrogen was estimated by Kjeldahl's method, by which all the nitrogen is converted into ammonia and estimated as ammonia sulphate; the urea was estimated by the sodium hypobromite method, and the ammonia by Schlösing's method. The results have shown uniformly an increase in the ammonia coefficient, whilst in the chronic nephritis cases such a rise has not been noted, except in one case where convulsions supervened, and in this case it is doubtful whether the convulsions should be regarded as uræmic or eclamptic. Observations in normal pregnancy have shown that from 80 to 85 per cent. of the nitrogen is excreted as urea and 4 to 5 per cent. as ammonia.

I will first give the figures we obtained in the cases of toxæmia :—

		Urea.	Ammonia.
Case 1	Eclampsia	63 per cent.	16 per cent.
„ 2	*Kidney of pregnancy*	71 „	12 „
„ 3	„ „	63 „	18 „
„ 4	Eclampsia	62 „	18 „
„ 5	„	51 „	16 „
„ 6	„	68 „	22 „
„ 7	Icterus gravis	63 „	17 „
„ 8	*Kidney of pregnancy*	74 „	10 „
„ 9*	„ „	63 „	21 „
„ 10	„ „	66 „	14 „

* Convulsions 10 days later.

It will be seen that in this series of cases the ammonia coefficient *is high throughout and the urea coefficient is diminished. It is also to be noted that the proportion of* undetermined nitrogen is usually high.

Let us now compare a series of six cases of chronic nephritis :—

			Urea.	Ammonia.
Case 1	Gravida	32 weeks.	82 per cent.	5 per cent.
„ 2	„	35 „	80 „	6 „
„ 3*	„	28 „	62 „	14 „
„ 4	„	30 „	87 „	4 „
„ 5	„	20 „	83 „	5 „
„ 6	„	38 „	78 „	7 „

* Convulsions ? uræmic ? eclamptic.

With the exception of Case 3 there is very little alteration of the urea-ammonia ratio, and further the urea + ammonia is practically a constant quantity. There is no marked increase in the quantity of undetermined nitrogen. The six water were prepared in strengths varying from 1 in 20 to 1 in 100. 0·25 c.c. of the serum was mixed with 0·25 c.c. of the acid solutions and the strength of the acid solution required to neutralise the equal volume of serum was ascertained, a standardised solution of litmus being used as the indicator. Wright's observations have shown that in a normal individual who is not pregnant the strength of the acid solution required to neutralise the serum is between 1 in 30 and 1 in 45, the average being 1 in 35. This may be expressed by the formula :—

$$\frac{N}{35} H_2SO_4$$

I first made a series of observations upon six pregnant women who had shown no signs of deviation from the normal. All the patients were between the thirty-second and fortieth weeks of pregnancy. The results of these observations were as follows :—

Case 1	32 weeks	$\frac{N}{38} H_2SO_4$
" 2	34 "	$\frac{N}{40}$ "
" 3	35 "	$\frac{N}{39}$ "
" 4	38 "	$\frac{N}{37}$ "
" 5	38 "	$\frac{N}{42}$ "
" 6	40 "	$\frac{N}{40}$ "

Three observations were taken in each case and the formula given is the mean of the three observations. Comparing these figures with those obtained by Wright it appears that normally there is a slight diminution in the alkalinity of the blood during pregnancy. In the cases of pregnancy toxæmia, however, the fall is generally marked and sometimes very striking. This is shown in the following table :—

Case 1	Eclampsia (after two fits)	$\frac{N}{68} H_2SO_4$
" 2	*Kidney of pregnancy*	$\frac{N}{54}$ "
" 3	Eclampsia (before fits)	$\frac{N}{70}$ "
" 4	Eclampsia (before fits)	$\frac{N}{48}$ "
" 5	Eclampsia (after seven fits)	$\frac{N}{72}$ "
" 6	Kidney of pregnancy	$\frac{N}{84}$ "
" 7	Kidney of pregnancy	$\frac{N}{62}$ "
" 8	Eclampsia (after one fit)	$\frac{N}{72}$ "
" 9	Eclampsia (before fits)	$\frac{N}{88}$ "

It will be seen that in all these cases the alkalinity of the blood was below that of normal pregnancy, but the fall in alkalinity bore no definite relation to the severity of the *toxæmia, for in* Case 9, a relatively mild case, the fall was greatest, whilst in Case 5 in which after many violent convulsions the patient died in coma the fall was much less marked. I ha[illegible] only four cases of [illegible] In each instance [illegible] casts and œdema was a marked symptom :—

Case 1	Gravida	36 weeks	$\frac{N}{40} H_2SO_4$
" 2	"	35 "	$\frac{N}{42}$ "
" 3	"	30 "	$\frac{N}{33}$ "
" 4	"	38 "	$\frac{N}{40}$ "

None of these cases had, or subsequently developed, uræmic convulsions. It will be seen that the fall in alkalinity was *not greater than that found in normal pregnancy.*

Criticism of these results.—In employing this method we cannot claim to estimate accurately the alkalinity of the blood, but having established a normal standard we can detect deviations from that standard, and this is all that is required for the purpose we have in view. Whether we are justified in regarding the diminished alkalinity of the blood as evidence of acidosis in these cases is another question altogether, for in eclampsia lactic acid can often be found in the blood, and it is quite possible that the fall of alkalinity is due in part at least to this cause. Lactic acid may be found after any violent muscular exertion, particularly if the supply of oxygen is deficient and has been detected in considerable quantities after the convulsions of uræmia; I have had no opportunity of examining the blood of a pregnant woman after uræmic convulsions. It must be borne in mind that in acidosis induced by the administration of mineral acids it is some time before the alkalinity of the blood is diminished, for the alkalies are extracted first from the tissues and from the blood only when the supply begins to fail, hence a diminished alkalinity is not to be looked for as an early sign of acidosis, and I have not found it in the slighter cases of toxæmia.

I feel justified, however, in concluding that in cases of albuminuria of doubtful origin in pregnancy the determination of the alkalinity of the blood should form part of the investigation and sometimes affords considerable help in reaching a diagnosis.

The Proportion of Nitrogen Excreted in the Form of Ammonia Salts.

In these series of observations I am greatly indebted to Dr. Priestley and Mr. Mackenzie Wallis, who have performed a considerable number of the estimations. The total nitrogen was estimated by Kjeldahl's method, by which all the nitrogen is converted into ammonia and estimated as ammonia sulphate; the urea was estimated by the sodium hypobromite method, and the ammonia by Schlösing's method. The results have shown uniformly an increase in the ammonia coefficient, whilst in the chronic nephritis cases such a rise has not been noted, except in one case where convulsions supervened, and in this case it is doubtful whether the convulsions should be regarded as uræmic or eclamptic. Observations in normal pregnancy have shown that from 80 to 85 per cent. of the nitrogen is excreted as urea and 4 to 5 per cent. as ammonia.

I will first give the figures we obtained in the cases of toxæmia :—

		Urea.	Ammonia.
Case 1	Eclampsia	63 per cent.	16 per cent.
" 2	*Kidney of pregnancy*	71 "	12 "
" 3	" "	63 "	18 "
" 4	Eclampsia	62 "	18 "
" 5	"	51 "	16 "
" 6	"	68 "	22 "
" 7	Icterus gravis	63 "	17 "
" 8	*Kidney of pregnancy*	74 "	10 "
" 9*	" "	63 "	21 "
" 10	" "	66 "	14 "

* Convulsions 10 days later.

It will be seen that in this series of cases the ammonia *coefficient is high throughout and the urea coefficient is diminished. It is also to be noted that the proportion of* undetermined nitrogen is usually high.

Let us now compare a series of six cases of chronic nephritis :—

			Urea.	Ammonia.
Case 1	Gravida ...	32 weeks. ...	82 per cent. ...	5 per cent.
" 2	" ...	35 " ...	80 " ...	6 "
" 3*	" ...	28 " ...	62 " ...	14 "
" 4	" ...	30 " ...	87 " ...	4 "
" 5	" ...	20 " ...	83 " ...	5 "
" 6	" ...	38 " ...	78 " ...	7 "

* Convulsions ? uræmic ? eclamptic.

With the exception of Case 3 there is very little alteration of the urea-ammonia ratio, and further the urea + ammonia is practically a constant quantity. There is no marked increase in the quantity of undetermined nitrogen. The six that must be investigated if an obscure case is to be elucidated As examples I will instance the following.

CASE 1 —An unmarried lady consulted me in 1890 for an error of refraction and came again in 1905-06
and later with an irido-cyclitis, she
she had spongy gums due to tartar
did not recover But when in Octobe
removed a mucous polypus from the
relieved dysmenorrhœa of some years
well and has not relapsed

CASE 2 —A girl came with irido-cyclitis and a septic mouth which was treated but the e
failed from 5 6 to 5/36
and was sent to a physi
a year's duration Fo
was 5/5

Tables IA and IIA will be of interest chiefly to the ophthalmic surgeon They record the number of different parts affected, in many patients the disease attacked more than one part In the septic group, Table IA, it will be noticed that the uveal tract is the part chiefly involved, hence the greater number of secondary cataracts, whereas in Table IIA the sclerotic and cornea, the retina and optic nerve are more frequently affected

Though it would appear to be obvious after seeing these tables that sepsis from pyorrhœa is an important agent in causing inflammation of the eye, nevertheless the general application of this view is not yet universally accepted It seems incomprehensible that a surgeon, whose single aim is to avoid sepsis in his operations can think it a matter of no importance that a person should have a chronic source of sepsis in any part of his body

The usual objection made is that one sees very bad cases of pyorrhœa in people who say that they are enjoying the best of health and who do not complain These objectors seem to forget that Nature begins to raise a protecting barrier the very moment that the tissues are irritated by bacterial toxins or are invaded by the bacteria themselves If the invasion is slow enough, as is the case in pyorrhœa the barrier is efficient and the individual does not appear to suffer Whereas when the micro organisms are introduced direct into the circulation there is no time for an efficient barrier to be raised As long as the patient is in fair health the barrier is capable of doing its work, but this barrier may give way directly the general resistance of the tissues is lowered under the strain produced by some other illness or by traumatism, either surgical or accidental Then the organisms or an excess of their toxins will be able to pass through the defending barrier and some tissue in the body may become the seat of disease The enormous number of cases of pyorrhœa that one sees and the comparatively small number of diseases resulting therefrom shows how very efficient Nature's barrier is

These people with bad pyorrhœa say, and presumably believe, that they are in the best of health They are, of course, living, without knowing it, over a hidden drain, which *is constantly emitting poison, in such an insidious* manner, however, that they are unaware that they could possibly feel in better health When the drain is removed they are astonished at their increased vigour and feeling of rejuvenation

Although marked and long standing cases of pyorrhœa are easily recognised and would be condemned as inimical to health by most surgeons I would like to draw the attention of my colleagues to the importance of recognising even mild cases of the disease, as they also can cause central choroiditis Quite recently an ophthalmic surgeon who recognises that pyorrhœa does cause central choroiditis sent me such a case for my opinion as to the cause The patient, a youth of 18, had been reported upon by a dentist, who said nothing about pyorrhœa, the edges of the gums were only just pink, but there were pockets between the molars

Some ophthalmic surgeons examine their own cases for pyorrhœa, but as this is not universal, though it is useful to be able to do so, and at times is necessary when the patient lives in the country, I have asked my son to take some
be
It
oop
is in contact with the edge of the gum and cannot be buried out of sight in a healthy mouth, whereas in the case of pyorrhœa the loop has sunk into a pocket out of sight, a second loop is being held on the edge of the tooth above the first to show its size

Until the medical profession at large recognise the importance of pyorrhœa and the gravity of leaving it untreated, one cannot reasonably expect the dental profession to do so either, especially as they are being taught to treat the mouth in a way that makes it impossible to avoid creating sepsis by putting on crowns and building bars and bridges that cannot be kept clean Until this policy is reversed and everything is done to enable the mouth to be kept aseptic, the loss of sight, and even total blindness due to pyorrhœa, will continue to occur

Our greatest hope of reform in the treatment of the mouth lies in imitating the Zulus and some other savages who rinse out their mouths and brush their teeth with a frayed out pencil of a special kind of wood at the end of every meal The condition of the mouths and teeth of these savages is the ideal for civilised communities Whereas, the condition of the mouths and teeth of neighbouring tribes, who do not follow this practice, can be seen any day in our hospital wards and out patient department If this habit of the Zulus were taught in early childhood and practised throughout life, there would be fewer blind eyes and much less ill health in the world

I am unable to express an opinion as to the merits of the various kinds of treatment for pyorrhœa that have been mentioned in this discussion, but as long as the protecting barrier is intact ionisation and local measures should be tried When this barrier has broken down and the eyes are affected by a serious inflammation which may destroy the sight, it is then too late to do anything except to remove the teeth at once Before the extraction the gums should be carefully cleaned and treated with antiseptics By doing so the amount of septic material that enters the system through the large raw, unprotected tooth sockets is greatly reduced. Failing this precaution, the eye frequently becomes worse immediately after the extraction If the sight is to be restored in a recent case of keratitis or of central choroiditis the affected teeth must come out on the chance that they are the cause, and if the inflammation does not subside then other possible causes must be investigated

I wish to draw especial attention to the baneful influence that a chronic septic focus frequently exerts upon eyes that have been operated upon The eye often becomes acutely inflamed, and remains red for a much longer period than the severity of the operation would warrant but rapidly quietens down when the exciting cause has been removed Although no permanent harm usually results, such a complication to the operation as this is to be avoided if possible, and therefore before I operate on any patient I always have the mouth examined and put in order if necessary and have a search made for other septic foci should there be any indication for so doing

I have devoted most attention to pyorrhœa because of its frequency in the present day, and consequently its importance to the ophthalmic surgeon The comparatively small number of my *cases attributed to the affections of the* alimentary tract shows that either toxæmia from stasis does not affect the eyes so frequently as pyorrhœa or that the majority of patients with stasis are too ill to trouble about their sight, and when they are cured the eyes have recovered That the alimentary tract is capable of producing central choroiditis is almost certain if one may judge by the effect produced by removing the appendix

CASE 3 —A Dominion surgeon brought his young wife for rapid loss of central vision in one eye with it she could only count fingers No definite cause for the central choroiditis could be found beyond very slight pyorrhœa which was very soon cured Improvement did not take place, and the vision of the second eye began to fail from the same affection In a week it had fallen

The following case illustrates the fact that the exposure was the exciting cause and the predisposing cause had been present without producing any effect for more than two years This cause consisted in a single septic sinus from an abscess of a root

CASE 4 —A physician in good health went for a day's fishing in mid October *before beginning* his duties as an examiner at the College When walking home in the evening he felt some discomfort in one eye and although this got worse he continued for some ten days to read that must be investigated if an obscure case is to be elucidated As examples I will instance the following.

CASE 1 —An unmarried lady consulted me in 1890 for an error of refraction and came again in 1905-06
and later with an irido-cyclitis, she
she had spongy gums due to tartar
did not recover But when in Octobe
removed a mucous polypus from the
relieved dysmenorrhœa of some years
well and has not relapsed

CASE 2 —A girl came with irido-cyclitis and a septic mouth which
was treated but the e
failed from 5 6 to 5/36
and was sent to a physi
a year's duration Fo
was 5/5

Tables IA and IIA will be of interest chiefly to the ophthalmic surgeon They record the number of different parts affected, in many patients the disease attacked more than one part In the septic group, Table IA, it will be noticed that the uveal tract is the part chiefly involved, hence the greater number of secondary cataracts, whereas in Table IIA the sclerotic and cornea, the retina and optic nerve are more frequently affected

Though it would appear to be obvious after seeing these tables that sepsis from pyorrhœa is an important agent in causing inflammation of the eye, nevertheless the general application of this view is not yet universally accepted It seems incomprehensible that a surgeon, whose single aim is to avoid sepsis in his operations can think it a matter of no importance that a person should have a chronic source of sepsis in any part of his body

The usual objection made is that one sees very bad cases of pyorrhœa in people who say that they are enjoying the best of health and who do not complain These objectors seem to forget that Nature begins to raise a protecting barrier the very moment that the tissues are irritated by bacterial toxins or are invaded by the bacteria themselves If the invasion is slow enough, as is the case in pyorrhœa the barrier is efficient and the individual does not appear to suffer Whereas when the micro organisms are introduced direct into the circulation there is no time for an efficient barrier to be raised As long as the patient is in fair health the barrier is capable of doing its work, but this barrier may give way directly the general resistance of the tissues is lowered under the strain produced by some other illness or by traumatism, either surgical or accidental Then the organisms or an excess of their toxins will be able to pass through the defending barrier and some tissue in the body may become the seat of disease The enormous number of cases of pyorrhœa that one sees and the comparatively small number of diseases resulting therefrom shows how very efficient Nature's barrier is

These people with bad pyorrhœa say, and presumably believe, that they are in the best of health They are, of course, living, without knowing it, over a hidden drain, which *is constantly emitting poison, in such an insidious* manner, however, that they are unaware that they could possibly feel in better health When the drain is removed they are astonished at their increased vigour and feeling of rejuvenation

Although marked and long standing cases of pyorrhœa are easily recognised and would be condemned as inimical to health by most surgeons I would like to draw the attention of my colleagues to the importance of recognising even mild cases of the disease, as they also can cause central choroiditis Quite recently an ophthalmic surgeon who recognises that pyorrhœa does cause central choroiditis sent me such a case for my opinion as to the cause The patient, a youth of 18, had been reported upon by a dentist, who said nothing about pyorrhœa, the edges of the gums were only just pink, but there were pockets between the molars

Some ophthalmic surgeons examine their own cases for pyorrhœa, but as this is not universal, though it is useful to be able to do so, and at times is necessary when the patient lives in the country, I have asked my son to take some
be
It
oop
is in contact with the edge of the gum and cannot be buried out of sight in a healthy mouth, whereas in the case of pyorrhœa the loop has sunk into a pocket out of sight, a second loop is being held on the edge of the tooth above the first to show its size

Until the medical profession at large recognise the importance of pyorrhœa and the gravity of leaving it untreated, one cannot reasonably expect the dental profession to do so either, especially as they are being taught to treat the mouth in a way that makes it impossible to avoid creating sepsis by putting on crowns and building bars and bridges that cannot be kept clean Until this policy is reversed and everything is done to enable the mouth to be kept aseptic, the loss of sight, and even total blindness due to pyorrhœa, will continue to occur

Our greatest hope of reform in the treatment of the mouth lies in imitating the Zulus and some other savages who rinse out their mouths and brush their teeth with a frayed out pencil of a special kind of wood at the end of every meal The condition of the mouths and teeth of these savages is the ideal for civilised communities Whereas, the condition of the mouths and teeth of neighbouring tribes, who do not follow this practice, can be seen any day in our hospital wards and out patient department If this habit of the Zulus were taught in early childhood and practised throughout life, there would be fewer blind eyes and much less ill health in the world

I am unable to express an opinion as to the merits of the various kinds of treatment for pyorrhœa that have been mentioned in this discussion, but as long as the protecting barrier is intact ionisation and local measures should be tried When this barrier has broken down and the eyes are affected by a serious inflammation which may destroy the sight, it is then too late to do anything except to remove the teeth at once Before the extraction the gums should be carefully cleaned and treated with antiseptics By doing so the amount of septic material that enters the system through the large raw, unprotected tooth sockets is greatly reduced. Failing this precaution, the eye frequently becomes worse immediately after the extraction If the sight is to be restored in a recent case of keratitis or of central choroiditis the affected teeth must come out on the chance that they are the cause, and if the inflammation does not subside then other possible causes must be investigated

I wish to draw especial attention to the baneful influence that a chronic septic focus frequently exerts upon eyes that have been operated upon The eye often becomes acutely inflamed, and remains red for a much longer period than the severity of the operation would warrant but rapidly quietens down when the exciting cause has been removed Although no permanent harm usually results, such a complication to the operation as this is to be avoided if possible, and therefore before I operate on any patient I always have the mouth examined and put in order if necessary and have a search made for other septic foci should there be any indication for so doing

I have devoted most attention to pyorrhœa because of its frequency in the present day, and consequently its importance to the ophthalmic surgeon The comparatively small number of my *cases attributed to the affections of the* alimentary tract shows that either toxæmia from stasis does not affect the eyes so frequently as pyorrhœa or that the majority of patients with stasis are too ill to trouble about their sight, and when they are cured the eyes have recovered That the alimentary tract is capable of producing central choroiditis is almost certain if one may judge by the effect produced by removing the appendix

CASE 3 —A Dominion surgeon brought his young wife for rapid loss of central vision in one eye with it she could only count fingers No definite cause for the central choroiditis could be found beyond very slight pyorrhœa which was very soon cured Improvement did not take place, and the vision of the second eye began to fail from the same affection In a week it had fallen

The following case illustrates the fact that the exposure was the exciting cause and the predisposing cause had been present without producing any effect for more than two years This cause consisted in a single septic sinus from an abscess of a root

CASE 4 —A physician in good health went for a day's fishing in mid October *before beginning* his duties as an examiner at the College When walking home in the evening he felt some discomfort in one eye and although this got worse he continued for some ten days to [illegible]

In cases of excessive absorption of alimentary toxins we [illegible] sia of the thyroid [illegible] course of this dis- [illegible] Rowell, and Mr. [illegible] en ileo-sigmoido- sto[illegible] of a goitre. [illegible] chain of evidence is afforded by [illegible] known as infective—arthritis. This disease is not uncommonly accompanied by enlargement of the thyroid gland, by Graves's disease, and by tetany, or a condition of the hands and feet closely resembling it. It is also regarded by many as an effect of oral sepsis or intestinal intoxication. An important support of this view is the work of Mr. Kenneth Goadby on the subject. Points which favour this contention are the almost invariable presence of oral sepsis, the beneficent effects, sometimes amounting to complete cure, which follow attention to the mouth; the improvement after lavage of the colon in some cases, and in a case recorded by Mr. Lane after ileo-sigmoidostomy.

In rheumatoid arthritis, then, we have a condition probably in many cases due to alimentary intoxication. In this condition overgrowth of the thyroid is apt to occur, and also tetany—a symptom of ineffective functioning of the thyroid gland—is found. Moreover, rheumatoid arthritis is occasionally distinctly benefited by the administration of thyroid extract.

Mr. Rupert Farrant has studied the effects of several types of clinical toxæmia upon the thyroid gland. The following changes occur: (1) the colloid becomes granular; (2) vacuolated and partially absorbed; (3) the cells become more numerous, elongated, and arranged in masses; (4) the colloid is entirely absorbed, and the walls of the vesicles become crenated and folded; and (5) the infolding and cell-increase go on to transform the vesicles into solid masses of cells. In other words, there is a reaction of the thyroid gland, with signs of hyperplasia and increased functioning, amounting in some cases to changes found in Graves's disease. This holds true for such diverse toxæmias as those of infantile diarrhœa, diphtheria, measles and broncho-pneumonia, and whooping-cough and broncho-pneumonia. A similar hyperplasia was caused in guinea-pigs by the injection of diphtheria toxin, but was mitigated if thyroid was given at the same time.

Equally conclusive inferences are to be drawn from the epoch-making researches embodied in the recent Milroy lectures of my friend, Major R. McCarrison, I.M.S., who has studied goitre as it occurs endemically in the valleys of Chitral and Gilgit in Northern India.[2] He has shown beyond dispute that thyroid enlargement can be produced experimentally in man, within a few weeks, by the administration of suspended matter separated by filtration from goitre-producing waters; and can be cured by taking thymol, one of the most powerful of gastro-intestinal antiseptics. He has shown that if the source of the toxin be avoided or removed the gland will return to normal size, unless secondary changes have occurred.

It is to be expected that, like other glands, the thyroid may undergo degenerative and retrogressive changes as the result of over-action. Normally at the menopause with the atrophy of the ovary part of its work ceases, and it is conceivable that if it has previously been subjected to undue activity its normal involution may overshoot the mark and lead to hypothyroidism and myxœdema. The last three cases of myxœdema which I have had under observation have all shown, together with severe oral sepsis and very offensive motions, anæmia of the pernicious form, which Dr. William Hunter has for so many years ascribed to lesions in the alimentary tract.

If the thyroid undergoes enlargement to combat undue toxæmia, it is reasonable to suppose that relieving it of part of its burden may cause a simple goitre to shrink, but this, of course, cannot be expected if adenomata or cysts are present. McCarrison has caused goitres to dwindle or disappear by using vaccines prepared from different forms of organisms—staphylococcus, a coliform bacillus, and a spore-bearing bacillus. The good results which he has obtained have led me to try a similar method of treatment, and I have followed out the plan which he adopted. The vaccines which I have generally employed have been prepared from the coliform bacilli of the patient's own bowel. The bacterial growth has been obtained from the fæces by culturing on Musgrave's medium, which consists of beef extract 0·5 gramme, sodium chloride 0·5 gramme, agar 20 grammes, tap water 1000 c.c., and is of an alkalinity of minus 1. This gives a growth of coliform bacilli of fairly constant character. The initial dose has been usually 125,000,000 of the dead organisms, suspended in about 1 c.c. of saline. Subsequently, if the goitre has shown signs of diminishing I have increased the dose weekly by 25,000,000 or 30,000,000. As a rule the injections have been given at weekly intervals.

It is too early to make any definite statement as to the results, but in the few cases, eight in all, treated they have been very encouraging. In one case the goitre disappeared entirely. In all the others it has diminished. As a rule, after the first injection the tumour becomes softer and, after subsequent doses, it gradually gets smaller, although occasionally periods of quiescence supervene. Two of the patients have been able to do up their neck-bands for the first time for several months after the first or second injection. A man who had taken to larger-sized collars is now wearing those of his ordinary size. One girl who had definite stridor, even when lying in bed, has now no embarrassment of breathing except slightly after exceptional exercise. All are charitable enough to say they are better and free from the symptoms which caused them to come for treatment, such as a feeling of suffocation and difficulty in swallowing and breathing.

Another effect has been that, by producing absorption of the parenchymatous enlargement, adenomata previously undetected have become obvious, and operative treatment has in this way been facilitated.

To sum up, the thyroid is a gland a useful function of which is to counteract intoxication. One of the sources of this intoxication is probably the bowel. If the intoxication be proportionately great for the gland, it undergoes hyperplasia and visible enlargement. If the amount of intoxication can be lessened the extra burden is removed and the gland diminishes. This has been done by the use of thymol and of vaccines, especially those prepared from cultures of the coliform organisms obtained from the patient's own intestinal flora.

INDICATIONS OF NERVE LESION IN CERTAIN PATHOLOGICAL CONDITIONS OF BLOOD-VESSELS.

BY T. WINGATE TODD, M.B. MANCH., F.R.C.S. ENG.,
PROFESSOR OF ANATOMY, WESTERN RESERVE UNIVERSITY,
CLEVELAND, OHIO, U.S.A.

SOME time ago it became apparent that the vascular symptoms so frequently associated with the sensori-motor syndrome of the affection often laconically designated "cervical rib" were probably produced by a lesion of the nerves supplying the blood-vessels of the arm. It was then obvious that the same explanation might afford a clue to the elucidation of many other obscure conditions. It was therefore my intention to investigate those other diseases to discover, if possible, whether any such relation existed in them between nerves and blood-vessels as has been shown to be present in cervical rib. Being aware of the difficulty of the problem and the many pitfalls which it presents I have been unwilling to write anything further on the subject until I possessed more extensive data than it is possible to submit at present. The appearance, however, of two recent papers bearing on the subject of blood-vessel changes consequent on nervous lesions would seem to make it advisable to review the work of recent investigators as a preliminary to further research.

Of the two papers mentioned above the first is one by Manouélian[1] showing that damage to nerves supplying the abdominal aorta and pulmonary artery results in localised areas of arterio-sclerosis typified by degeneration of elastic fibres and smooth muscle fibres with hyperplasia of the connective tissue of the media, together with intimal proliferation. The same results have been obtained in the case of the vessels to the ear after section of the cervical sympathetic by numerous workers, among whom may be

REMARKS ON

ABNORMAL INTRA-ABDOMINAL DEVELOPMENTAL ADHESIONS

BY H M W GRAY, M B, C M ABERD, F R C S EDIN,
SURGEON AND LECTURER ON CLINICAL SURGERY, ROYAL INFIRMARY, ABERDEEN, SURGEON TO THE ROYAL HOSPITAL FOR SICK CHILDREN ABERDEEN,

AND

WILLIAM ANDERSON, M B, CH B ABERD, F R C S EDIN

(Concluded from p 1300)

TREATMENT

General remarks —Where such "developmental adhesions" are suspected we consider that a central vertical incision is usually the most suitable, as it can be varied in height and length according to necessity We prefer a right paracentral incision with displacement of the rectus muscle outwards During any intra abdominal operation, if the condition of the patient permits, we make a systematic investigation of all organs, because we believe very strongly in the theory that disease of one abdominal organ deleteriously affects the function of others, and because in many cases it is difficult to adjudicate precisely cause and effect For example, the relationship between appendicitis and kinks and duodenal ulcer is still under discussion If "adhesions" are tense enough to prevent perfectly free movement of the part concerned, we think it is justifiable to treat them, although there may not have been hitherto any symptoms referable to their presence Such adhesions are potential of evil, and we think that prevention is better than cure We have noted that these adhesions are most likely to give trouble in middle aged people

We do not approve of the small "button hole" incision too often made in interval operations for appendicitis It is futile to imagine that the lower end of the ileum can be satisfactorily examined through a tiny opening, and we feel that this should be done in every case, however definite the symptoms of appendicitis are

We think that the operation of "short circuiting" the bowel, and still more that of excision of the colon, is justifiable in only a very few cases such as those in which the transverse colon is densely adherent to either the ascending or descending colon, or possibly where the poor condition of the patient does not admit of the manipulations necessary to thoroughly investigate and treat cases in the way we suggest

An important point in deciding as to whether any of these developmental adhesions are the cause of symptoms, be they affecting gall bladder, duodenum, ileum, or colon, is the presence of [illegible] hollow organ [illegible] the cæcum is [illegible] pathological adhesions in the colon beyond it, if it is dilated, hypertrophied, and possibly dropped, or unusually mobile, there is certain to be obstruction at some of the flexures, in the majority of cases at the hepatic

Owing to the fact that there is considerable exposure and handling of different parts of the abdominal contents during operation the bowel is apt to remain quiescent for many hours and adhesions may form during that time as the result of the irritation At the end of 18 to 24 hours, therefore one's object should be to stimulate the bowel to action by the giving of food of reasonable quality and quantity if the patient is not sick, and by the administration of evacuating enemata, and such stimulants to peristalsis as eserine, pituitrin, or mild aperients If distension is troublesome calomel in repeated small doses seems to act as well as anything A very usual procedure on the afternoon of, at latest, the third day is to give 1 gr of calomel every hour from three to five doses, if the bowels have not moved by 7 A M next morning to give a dose of salts, and if no action by 10 A M to give a turpentine enema Every second day if the bowels do not move spontaneously an aperient is given Solid food is given as soon as patients feel inclined for it, and as convalescence progresses such foods as will help to promote peristalsis and prevent constipation are recommended.

The patients are placed in the Fowler position immediately after operation and usually remain in that position for 24 hours Thereafter they can assume whatever position is most comfortable, and are encouraged and helped to change their position fairly frequently

(a) *Terminal ileal membrane* —This should be incised, as indicated in the illustration (Fig 5) parallel to the anti mesenteric border of the ileum in such a manner that the edge of the upper flap of the membrane can be stitched to *the bowel at its mesenteric attachment taking care not to* injure or occlude vessels in so doing The raw area which is exposed when the ileum is made to assume its proper position can, in many cases, be obliterated by sliding and suturing the peritoneum as shown (Figs 5 6, 7) If this cannot be done without kinking the bowel, it is apparently equally satisfactory to transplant a suitably sized piece of omentum, carefully tucking in the raw edges thereof As a point of technique it is better, in fixing the omentum, to push the needle first through the omentum and then through the peritoneum of the bowel or mesentery Otherwise the omental flap is difficult to retain at first in proper position as it is lifted away while the sutures are being drawn through

(b) *Jackson's membrane* should be very freely divided between ligatures, along the outer side of the colon Care must be taken that the colon is thoroughly freed from any bands which may limit its motility This is especially important at the hepatic flexure which should at the end of the proceeding have a rounded instead of an acute curve The mistake usually made is in not dividing the membrane freely enough or high enough (Fig 8) Only in rare instances is it necessary to transplant a piece of omentum to cover raw areas

(c) *Cæcum mobile* —Because, in our opinion, this condition, when causing symptoms, is practically always associated with kinking at the hepatic or *splenic flexures* the first indication is to free those kinks It is then a matter for the operator to judge as to whether, in order to ensure success, he will fix the cæcum and lower part of the ascending colon or not by some such procedure as that suggested by Wilms—namely, to incise vertically and raise the dorsal parietal peritoneum of the flank in such a manner that the outer part of the cæcum and ascending colon can be inserted beneath it The edge of the peritoneum is sutured to the *anterior aspect of these organs*

(d) *Splenic kink* —The adhesions causing this kink are treated in exactly the same way as those forming Jackson's membrane

(e) *Meso-sigmoid adhesions* —The treatment of these is best indicated by the accompanying illustrations (Figs 9 and 10) which show the condition after division and suture respectively of the adhesions [1] In some cases, owing to the irregular raw surface left after their separation or where rapidity is important owing to *the condition of the patient*, perfectly satisfactory results can be obtained by inserting a detached flap of omentum and fixing it in position by a few sutures

Where adhesions bind the ascending and transverse, or transverse and descending colons very extensively together, we believe that a short-circuiting operation is preferable, and in very bad cases, in order to save time, it is probably wise to make an ileo proctostomy where meso sigmoid adhesions exist (see our previous paper)

(f) *Gall bladder adhesions* —We believe that where adhesions exist which seriously interfere with the emptying of the gall bladder and give rise to definite symptoms, cholecystectomy should be the operation of choice So far as we can make out the tendency in dealing with these cases has been to make merely a cholecystostomy Prolonged drainage brings about, no doubt, a shrinking of the walls of the gall bladder, which after the fistula has healed, prevents recurrence of symptoms for a variable period The danger in such cases, whether the adhesions have been divided or not, is that sacculation and kinking will sooner or later recur, with repetition of the same severe symptoms This actually occurred in two of our cases Where these adhesions have seriously tucked up the pylorus or duodenum, causing gastrectasis or gastroptosis, we think that it is advisable, in order to procure more rapid convalescence and to obviate future disability, to perform a posterior gastro enterostomy

We think that the operation of "short circuiting" the bowel, and still more that of excision of the colon, is justifiable in only a very few cases such as those in which the transverse colon is densely adherent to either the ascending or descending colon, or possibly where the poor condition of the patient does not admit of the manipulations necessary to thoroughly investigate and treat cases in the way we suggest

An important point in deciding as to whether any of these developmental adhesions are the cause of symptoms, be they affecting gall bladder, duodenum, ileum, or colon, is the [illegible] hollow organ [illegible] the cæcum is [illegible] y pathological adhesions in the colon beyond it, if it is dilated, hypertrophied, and possibly dropped, or unusually mobile, there is certain to be obstruction at some of the flexures, in the majority of cases at the hepatic

Owing to the fact that there is considerable exposure and handling of different parts of the abdominal contents during operation the bowel is apt to remain quiescent for many hours and adhesions may form during that time as the result of the irritation At the end of 18 to 24 hours, therefore one's object should be to stimulate the bowel to action by the giving of food of reasonable quality and quantity if the patient is not sick, and by the administration of evacuating enemata, and such stimulants to peristalsis as eserine, pituitrin, or mild aperients If distension is troublesome calomel in repeated small doses seems to act as well as anything A very usual procedure on the afternoon of, at latest, the third day is to give 1 gr of calomel every hour from three to five doses, if the bowels have not moved by 7 A M next morning to give a dose of salts, and if no action by 10 A M to give a turpentine enema Every second day if the bowels do not move spontaneously an aperient is given Solid food is given as soon as patients feel inclined for it, and as convalescence progresses such foods as will help to promote peristalsis and prevent constipation are recommended.

The patients are placed in the Fowler position immediately after operation and usually remain in that position for 24 hours Thereafter they can assume whatever position is most comfortable, and are encouraged and helped to change their position fairly frequently

(a) *Terminal ileal membrane* —This should be incised, as indicated in the illustration (Fig 5) parallel to the antimesenteric border of the ileum in such a manner that the edge of the upper flap of the membrane can be stitched to the bowel at its mesenteric attachment taking care not to injure or occlude vessels in so doing The raw area which is exposed when the ileum is made to assume its proper position can, in many cases, be obliterated by sliding and suturing the peritoneum as shown (Figs 5 6, 7) If this cannot be done without kinking the bowel, it is apparently equally satisfactory to transplant a suitably sized piece of omentum, carefully tucking in the raw edges thereof As a point of technique it is better, in fixing the omentum, to push the needle first through the omentum and then through the peritoneum of the bowel or mesentery Otherwise the omental flap is difficult to retain at first in proper position as it is lifted away while the sutures are being drawn through

(b) *Jackson's membrane* should be very freely divided between ligatures, along the outer side of the colon Care must be taken that the colon is thoroughly freed from any bands which may limit its motility This is especially important at the hepatic flexure which should at the end of the proceeding have a rounded instead of an acute curve The mistake usually made is in not dividing the membrane freely enough or high enough (Fig 8) Only in rare instances is it necessary to transplant a piece of omentum to cover raw areas

(c) *Cæcum mobile* —Because, in our opinion, this condition, when causing symptoms, is practically always associated with kinking at the hepatic or splenic flexures the first indication is to free those kinks It is then a matter for the operator to judge as to whether, in order to ensure success, he will fix the cæcum and lower part of the ascending colon or not by some such procedure as that suggested by Wilms—namely, to incise vertically and raise the dorsal parietal peritoneum of the flank in such a manner that the outer part of the cæcum and ascending colon can be inserted beneath it The edge of the peritoneum is sutured to the anterior aspect of these organs

(d) *Splenic kink* —The adhesions causing this kink are treated in exactly the same way as those forming Jackson's membrane

(e) *Meso-sigmoid adhesions* —The treatment of these is best indicated by the accompanying illustrations (Figs 9 and 10) which show the condition after division and suture respectively of the adhesions[1] In some cases, owing to the irregular raw surface left after their separation or where rapidity is important owing to the condition of the patient, perfectly satisfactory results can be obtained by inserting a detached flap of omentum and fixing it in position by a few sutures

Where adhesions bind the ascending and transverse, or transverse and descending colons very extensively together, we believe that a short-circuiting operation is preferable, and in very bad cases, in order to save time, it is probably wise to make an ileo proctostomy where meso sigmoid adhesions exist (see our previous paper)

(f) *Gall bladder adhesions* —We believe that where adhesions exist which seriously interfere with the emptying of the gall bladder and give rise to definite symptoms, cholecystectomy should be the operation of choice So far as we can make out the tendency in dealing with these cases has been to make merely a cholecystostomy Prolonged drainage brings about, no doubt, a shrinking of the walls of the gall bladder, which after the fistula has healed, prevents recurrence of symptoms for a variable period The danger in such cases, whether the adhesions have been divided or not, is that sacculation and kinking will sooner or later recur, with repetition of the same severe symptoms This actually occurred in two of our cases Where these adhesions have seriously tucked up the pylorus or duodenum, causing gastrectasis or gastroptosis, we think that it is advisable, in order to procure more rapid convalescence and to obviate future disability, to perform a posterior gastro enterostomy

---

[1] Owing to consideration of space six illustrations have been omitted.

Now if there is any organism that varies in its cultural, morphological, and pathogenic properties it is the cholera vibrio, and from the latest investigations, with the most modern bacteriological technique, it is stated that "the power of anti cholera serum to agglutinate the vibrio is very variable," and "that because either agglutination or Pfeiffer's test is negative, it does not follow that in the presence of an epidemic a vibrio not responding to these tests should not be considered to be a *cholera vibrio for all* practical purposes". Under the circumstances I consider that from our investigations it is proved that this well water was infected with material from a cholera patient, and that it was possible many other wells and tanks and water vessels *were infected in a similar way This is as far as* any observers have ever got in the bacteriology of the disease, and until we know more we must assume that cholera is spread in this way I maintain that for the practical sanitarian this is enough to work upon Given an outbreak of cholera whether imported or indigenous, any sample of water from which a pure culture of the comma vibrio is obtained is sufficient evidence for active preventive measures The municipal laboratory cannot however, for obvious reasons undertake that high standard of research which this question deserves

I am strongly *of opinion that the cholera vibrio after* it leaves the human body undergoes such rapid modifications in water, milk food, soil or even on the soiled clothes and discharge of the suffering person, as to render it almost unrecognisable The organism, fortunately for the human race, is very faintly resistant to external influences, and it is for this reason that, when an outbreak occurs prompt sanitary measures can control it How far, and how long, a cholera vibrio can retain its virulence, externally to the human body, and how far the other organisms in water affect it, are still subjects for further investigation How the attenuated organism found in water, can again retain its virulence when entering the body of its former host is what we want to know Until then the practical sanitarian must consider all water containing a comma vibrio, in the presence of a cholera outbreak a danger, which by all the means in his power should be attacked

Without entering into the bacteriology of the innumerable cholera like vibrios found in water and fæces, the presence of a comma vibrio in water during a cholera epidemic is evidence of contamination from a case of cholera It is, as I have already pointed out, held that *infected water* is always the cause of the spread of cholera and that personal contact has little to do with the spread of the disease Now, it is impossible to analyse the evidence collected during the outbreak in Bombay without coming to the conclusion that the personal element has a great deal to do with the spread of cholera in India Without labouring too much on the habits and customs of the people, I am strongly of opinion that the spread of cholera is greatly due to direct *infection from* person to person by means of the discharges, contaminated hands food, vessels, milk and water, and flies The filthy privy baskets overflowing into open drains and thus soaking into subsoil or storm water drains the position of the water sewer pipes and the common washing places are a constant danger at any time but in the presence of cholera must contribute to a large extent to the circumstances favouring the spread *of the disease For example* on visiting a person suffering from the disease, he or she will be surrounded with relatives and friends handling the patient Many will be found occupying the same room, sleeping on the floor, they all use the same privy and washing place and eat from the same vessels, the water is stored in wooden iron, earthenware or other vessels in the living room cookroom or *nahani* for days together The friends and relatives will wash the dead body and take it to the burial ground or burning ghat and afterwards wash in the nearest tank or bathing place without any disinfectant precautions Anyone familiar with the homes of the poor can easily understand how cholera is thus spread

Conclusions

What we want to know is how far a person convalescent from the disease or suffering from it in a mild unrecognised form, can be a danger to the community as a 'carrier' May such a case, unknowingly, convey the infection to *nahanis*, privies, washing and drinking vessels or the food supply, or even a public water supply, and thus start an outbreak in the neighbourhood?

May and June were unusually hot months The municipal water-supply had been curtailed in B Ward On June 10th, and some days previous, large collections of Mahomedans congregated in *Mandvi, Umerkhadi, and Chuckla. Water* had to be provided for these large crowds Given, then, a few cases of cholera in these sections, it is possible that facilities were offered to the pollution of the temporary water supply provided for the people, which was infected *and thus caused the sudden rise in the incidence of the* disease As soon as the temporary supply of water was abolished, tanks and wells disinfected and cleaned, the disease began to disappear According to the bacteriological report the cholera vibrio was only found in one tank, but as many of the others had already been cleaned or disinfected it is not to be expected that this very volatile organism would be found there

This is nothing new in the epidemiology of cholera, as witness the fairs held in India Large crowds of people assemble, cholera breaks out and is checked only when the fair is over or the proper sanitary precautions have been taken to prevent the pollution of the water supply, and other sanitary precautions observed with regard to food and cleanliness of the camps, and to the destruction of all infected material Many persons leaving the fairs perfectly *well are attacked or die on their* way home or recover and return to their homes convalescent, thus becoming a focus to spread the disease elsewhere Facilities of transit are so many that the disease may be carried hundreds of miles in a few hours Bombay city is a very small unit of the Indian Empire, *or* even of the Bombay Presidency, but it is the haven of refuge for the destitute as well as the prosperous in times of famine and sickness in the neighbouring districts, and thus pays the penalty of its position The difficulties of obtaining information from the friends and relatives of infected people, and the passive resistance to any sanitary measures, make it extremely difficult to trace cases of infectious disease or to adopt measures for their control The indifference and carelessness on the part of the poor people to accept any advice add to the difficulties of control, while the ignorance of any measures of personal hygiene and the rooted objection to any innovation in their domestic arrangements form obstacles difficult to overcome

The bacteriological examinations were carried out by the municipal analyst, Dr L Joshi, and his assistant, Mr Pansari

A CONTRIBUTION TO THE ETIOLOGY OF RHEUMATOID ARTHRITIS

BY H WARREN CROWE M D OXON, M R C S ENG,
L R C P LOND

THE etiology of chronic arthritis has recently gained prominence from the accidental discovery by many therapeutists that the administration of vaccines for such apparently diverse conditions as post nasal catarrh, pyorrhœa bronchitis gastritis, cystitis, colitis (to name those that first occur to the mind) is frequently followed by the disappearance of muscular and arthritic pains It has been my personal experience, shared doubtless by others, that this rather remarkable by product of induced immunisation occurs when a streptococcus has been found to be the offending organism It seldom occurs with any other microbe save only in that form of chronic arthritis which is most commonly designated rheumatoid arthritis Here vaccines prepared from bacillus coli staphylococcus aureus as well as streptococci isolated from some local area of infection, have in some cases given relief to this otherwise intractable malady

A paper by Dr R McLeod Veitch,[1] of Harrogate illustrates remarkably *clearly* this point *in regard to* rheumatoid arthritis Where he finds a localised bacterial focus vaccines give relief to the general condition, where no focus is found a variety of similar vaccines produce no effect whatever On the face of it then one would say that rheumatoid arthritis is a disease which may be produced by a variety of infections It may be so At the same time there is at least one other possible explanation, for example there might be a primary organism and the successful vaccine

Incidence of the Staphyloid Coccus A.

In presenting reliable data on this point it is necessary to exclude all cases examined prior to the complete differentiation of this organism from the other members of the group. I can only therefore employ figures for the last nine months or so.

Table of Organisms Cultured from Urine.

In—	Staphyloid coccus A.	Strepto-cocci.	Bacillus coli.
14 cases of rheumatism	5	8	0
3 cases of neuritis	2	3	0
22 cases of rheumatoid arthritis	14	6	5

In regard to rheumatoid arthritis and staphyloid coccus A the proportion 14 to 22 is probably considerably understating the case, because three of the remaining cases gave marked [illegible] o more reacted in such a way [illegible] at it was distinctly borne in [illegible] A was pathogenic in those individuals. If these additional figures are added, we find that out of 22 cases 19 were almost certainly infected by staphyloid coccus A.

Treatment.

In the following article Dr. A. Bertram Soltau gives his impressions of the treatment of rheumatoid arthritis by vaccines, both autogenous and stock. The most valuable of the latter turned out to be one prepared from two strains of staphyloid coccus A, each isolated from a case of acute rheumatoid arthritis following parturition, in which I found the organism present in large numbers and in pure culture in the urine. Under this heading, then, I will only urge extreme caution in the use of staphyloid vaccine, if success is to be achieved in arthritis. Even a dose of 500,000 may cause a most unpleasant reaction, and until the urine is free from organisms, more than 5,000,000 can seldom be given. It is for this reason more than any other that it seems to me important for the present to keep a title which will distinguish this germ from the staphylococci.

In conclusion, one must admit that there is a long gap between describing an organism present in a disease and proving a direct pathological connexion; only prolonged experience and careful investigation will lead to the truth. I trust, however, that I have made good this point: that a certain organism, styled temporarily for the purposes of this paper "staphyloid coccus A," occurs with remarkable frequency in rheumatoid arthritis. Is the connexion between them causal, or is it merely casual?

Yelverton, Devon.

A NOTE ON

THE USE OF VACCINES IN THE TREATMENT OF RHEUMATOID ARTHRITIS.

BY A. BERTRAM SOLTAU, M.D. LOND., F.R.C.S. ENG.,
PHYSICIAN, SOUTH DEVON AND EAST CORNWALL HOSPITAL, PLYMOUTH.

THE treatment of rheumatoid arthritis has presented so many difficulties, and has so frequently been followed by failure or by relapse, inducing a feeling of hopelessness in both patient and practitioner, that any therapeutic measure which gives more hopeful results would be welcome.

Many investigators [illegible] cause for the disease, [illegible] and some encouragi[illegible] been reported. The variety of organisms which have been [illegible] lesions are due to many [illegible] e absence of any constant [illegible] obstacle to any marked advance in treatment.

In the preceding article Dr. H. Warren Crowe describes several "staphyloid" cocci ("staphyloid" on account of their resemblance to staphylococci), one of which, staphyloid coccus A, he has found to recur with remarkable frequency in cases of rheumatoid arthritis. As I have had the opportunity of using the vaccine prepared therefrom in a considerable number of cases a brief account of the results obtained may prove of interest.

A certain proportion of the cases showed a single infection with coccus A, whilst in the others, which formed the majority, the infection was mixed, the other co-existing organism being frequently a streptococcus, and occasionally bacillus coli communis. In the cases where a mixed infection was present the clinical course followed has been to treat the patient first with a vaccine prepared from what we have regarded as the secondary organism, streptococcus, bacillus coli, &c. It is noteworthy that whilst the joint condition had been thereby ameliorated and the patient has experienced a sense of improved well-being, a complete arrest of the articular lesions has not been obtained by the use alone of the vaccine of the secondary organism, but the diminution of the latter, as proved by cultural tests on the urine, has paved the way for the use of coccus A vaccine. The subsequent employment of the latter has then been followed by a very marked improvement in the arthritis, amounting in some cases to an apparent cure. The word "apparent" is used advisedly, because the lapse of time is yet far too short to allow of any dogmatic statements as to cure.

As regards the type of case treated, no attempt has been made at selection, and the degree of infection has varied considerably, from cases of long standing in which a large number of joints were affected and osseous deformity was present to a considerable degree, to those in which the infection was in an early stage, little more than neuritic pain in the limbs with slight swelling in a few joints being complained of. In two cases the disease was following an acute pyrexial course.

Of the cases being treated by coccus A vaccine nine are so far advanced that it is possible to form some idea as to their progress.

The system employed has been, in the main, as follows. A [illegible] is made, and if coccus A [illegible] vaccine is now employed. [illegible] two strains, each obtained from an advanced case of arthritis following parturition. As remarked before, in mixed infections the allied organisms are first attacked by autogenous vaccines, coccus A being used either concurrently or subsequently. The question of dosage has been a most difficult one to determine, owing to the marked reaction which sometimes follows even minute doses, such as 500,000. In one case the dose had to be reduced to one of 150,000 at first. It has therefore been necessary to proceed with great caution, and my usual practice has been to start with 500,000, raising the subsequent doses by very small increments of 500,000 or even less. Even then it has not always been easy to prevent excessive reactions, and at times a reversion to the earlier minute doses, after reaching a dose of 3,000,000 or 4,000,000, has been necessitated. The reaction has usually been an exacerbation of joint pains and swelling, with slight rise of temperature. The injections are usually made at weekly intervals, but here again each case has required treatment to be modified by its particular reaction, and one obstinate case only began to improve when the period between the injections was reduced to five days. In two cases, where reaction was so marked as to prevent any real advance, a great help was experienced by the injection of ½ c.c. of 4 per cent. solution of eucaine lactate in carbolised saline with each dose of vaccine.

The clinical course which the cases have followed has been on the whole a similar one, though the degree of rapidity of progress has varied within wide limits. The first favourable symptom has been the diminution of nocturnal pain, in itself no small advance, as it has permitted more sleep and an improvement in general health. The neuritic pain so often complained of has usually been relieved more rapidly than the articular pain. This raises an interesting etiological question as to the actual way in which the infection of rheumatoid arthritis acts. The theory so long maintained that rheumatoid arthritis was a disease of nervous origin, as evidenced by the glossy skin, the trophic nails, and the articular changes so similar to those of the neural arthropathies, may be coördinated to the microbic theory by regarding the infection as primarily one of the peripheral nerves, so leading to trophic changes in the joints and other structures. In two cases where the sole complaint was that of pain in the limbs without any joint changes the isolation by Dr. Crowe of coccus A and the employment of the vaccine was followed by rapid improvement. Both cases were pursuing a maintained pyrexial course, one being so severe as to resemble acute febrile polyneuritis. This is suggestive as the possible line of infection which ultimately

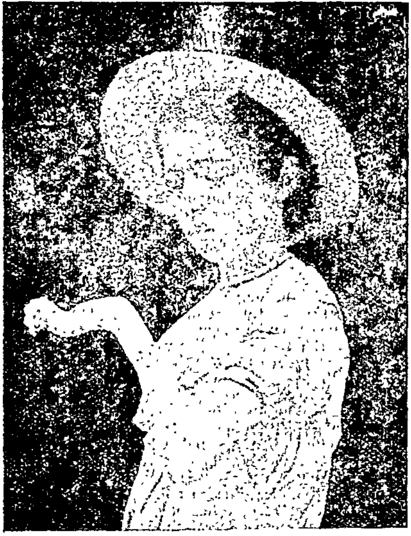
In two cases, where reaction was so marked as to prevent any real advance, a great help was experienced by the injection of ½ c.c. of 4 per cent. solution of eucaine lactate in carbolised saline with each dose of vaccine.

The clinical course which the cases have followed has been on the whole a similar one, though the degree of rapidity of progress has varied within wide limits. The first favourable symptom has been the diminution of nocturnal pain, in itself no small advance, as it has permitted more sleep and an improvement in general health. The neuritic pain so often complained of has usually been relieved more rapidly than the articular pain. This raises an interesting etiological question as to the actual way in which the infection of rheumatoid arthritis acts. The theory so long maintained that rheumatoid arthritis was a disease of nervous origin, as evidenced by the glossy skin, the trophic nails, and the articular changes so similar to those of the neural arthropathies, may be coördinated to the microbic theory by regarding the infection as primarily one of the peripheral nerves, so leading to trophic changes in the joints and other structures. In two cases where the sole complaint was that of pain in the limbs without any joint changes the isolation by Dr. Crowe of coccus A and the employment of the vaccine was followed by rapid improvement. Both cases were pursuing a maintained pyrexial course, one being so severe as to resemble acute febrile polyneuritis. This is suggestive as the possible line of infection which ultimately with the right (normal) one. There [illegible] ances. Most of the muscles reacted [illegible] feebly. The extensors of the wrist [illegible]

FIG. 1.



From a photograph of the patient before treatment.

flexors; extensors of the fingers more than their flexors. The finer difference between flexor digitorum sublimis and profundus could not be found out. Pronation and supination possible though limited.

The whole examination was attended with many difficulties on account of the nervous condition of the patient, who for a long time resisted the testing of her muscles. A radiograph taken in the course of the present treatment proved an old fracture of the radius about 2 inches below the elbow and of the lower end of the humerus.

This description will suffice to show that this case is an instance of an ischæmic contracture in which the extensors of the wrist and flexors of the fingers suffered most of all; shortening of their antagonists, the flexors of the wrist and extensors of the fingers, explains the deformity of the hand: flexion of the wrist and hyperextension of the fingers.

The treatment was directed first towards overcoming the contraction of the antagonists, thus giving those muscles which suffered worst a chance to recover, and then towards strengthening them. Of course, these two principles were combined, although so long as the stronger muscles were shortened there was practically no possibility of improvement in the weaker ones.

The first part of the treatment was carried out by means of passive movements, massage, and various splints, their shape and application being altered practically every week. I started with an ordinary splint applied to the palmar surface of the hand and forearm reaching as far down as the lower palmar crease [illegible] free. During [illegible] three times a [illegible] in order to stretch the contracted muscles and their tendons and to loosen stiff ligaments and joint capsules. Once I tried to stretch these structures under gas, hoping thus to overcome the resistance more easily; but I soon found that it would have been easier to dislocate the small bones than to stretch the tendons, and therefore I gave up the idea of any forcible action. The Latin proverb, "Gutta cavat lapidem non vi, sed saepe cadendo," here held good. At each sitting I gave massage alternating with movements.

[illegible] metacarpals. I tried to prevent this by wrapping up the hand in a piece of lint with spread boracic ointment before putting on the well-padded splint. However, in course of time the nutrition of the skin improved simultaneously with the deeper structures, so that now it can stand any pressure with impunity.

Since November last year the patient has been attending King's College Hospital, where she has been able to receive treatment more regularly—that is, four to five times a week instead of two to three times as before. This had a striking effect: not only did the passive movements improve but also, and what is of more importance, the active movements began to progress rapidly. The muscles began to react to faradism more promptly, with, however, the exception of the flexor digitorum profundus. I applied every day Bier's elastic bandage for about 15 to 20 minutes before the massage and exercises started. This seemed to help in softening all tissues, filling their vessels more abundantly with blood. This procedure was, however, apparently a little painful, or rather felt "queer" as the patient declared. Therefore I substituted active hyperæmia for the passive hyperæmia, giving her every day a hot arm bath before any manipulations were commenced. This proved to be pleasanter and equally beneficial. I have also found elastic extension of great service as applied to the fingers by means of rubber tubes.

Fig. 2 shows the present condition of the hand. The patient can extend her wrist actively and within the possible range. The hyperextension of the metacarpo-phalangeal joints has been overcome, and the patient can flex her fingers so far as to be enabled to hold light objects and to shake hands. A complete extension of the fingers (180°) is not possible yet because of the relative hypertrophy

SPECIAL MEETING OF FELLOWS

Completed Discussion on Alimentary Toxæmia [1]

A MEETING of the Fellows of this society was held on May 7th Sir FRANCIS H CHAMPNEYS, the President, being in the chair

Dr H D ROLLESTON said that as the uninjured skin was comparatively impervious the other surface covering of the body or the mucous membranes constituted the main inlet for microbes and poisons, and of the various mucous tracts that of the alimentary was much the largest, and further was much the most exposed to infection and intoxication It was true that the exposed condition of the alimentary canal was specially protected by the acid gastric juice against microbic activity and by the liver against poisons, but these lines of defence might be overwhelmed and broken down It was easy to argue that a very large number of the diseases to which flesh was heir were due to intestinal toxæmia but the state of our present knowledge made caution necessary Still, although it might be difficult to prove the widespread influence of alimentary toxæmia it was unwise to put aside possibilities until they could definitely be ruled out A difficulty about a wide assumption as to the existence of alimentary toxæmia in the sense in which it was employed in this discussion—namely effects in other parts of the body due to poisons apart from micro organisms—was that many of the effects assumed to be toxic might be due to the passage of micro organisms in small numbers into the circulation, and so into the tissues The hypothesis of such an escape of micro organisms had long been before us in Adami s sub infection with B coli which he (Adami) suggested played some part in the production of cirrhosis, hæmochromatosis, and pernicious anæmia With the improvements in our methods of blood culture bacteriæmia was now more commonly recognised and in the future transient and comparatively non virulent forms might be found to be more common than was generally realised Another point to be borne in mind in this discussion was that the same result—for example nephritis, neuritis, or arthritis—might be brought about in different ways, by different forms of toxæmia, of which alimentary toxæmia was one Therefore in considering the influence of alimentary toxæmia it was not necessary to argue that it was the exclusive cause of certain conditions The large subject of alimentary toxæmia might be divided in the first place into the results due to (1) alterations in the quality and quantity of the foodstuffs introduced into the intestine, (2) the activity of micro organisms in the intestine To refer in the first place to idiosyncrasies to certain foods it was true that the hypersensitiveness might depend on changes in the blood and tissues the intestine being merely the passive transmitter, but on the other hand the digestive processes might be congenitally so modified or the circumstances so altered by a change of the intestinal flora as to produce poisons out of ordinary food—e g, an abnormal cleavage of proteins and other bodies Thus family periodic paralysis might conceivably be due to a congenital metabolic defect, which in the presence of unsuitable food gave rise to the formation of poisons in the intestine (Gardner) This subject had been discussed by Dr Vaughan Harley, who suggested that the idiosyncrasy of some persons to eggs which was now commonly quoted as an example of anaphylaxis was due to the cleavage of lecithin into cholin which might eventually yield the poisonous body neurin Apart from any active toxic properties alteration in the quality and quantity of the food stuffs might so modify metabolism that morbid changes and symptoms were produced Our knowledge of 'the nutritional importance of the presence in dietaries of minute amounts of certain accessory substances which might possibly activate metabolism was only in its infancy To turn to the more commonplace results of excessive quantities of food, an excess in the intake of proteins was commonly regarded as one of the causes of arteriosclerosis by raising the blood pressure either (1)

e peripheral field or (2), and

to later, by primarily acting

yroid It had recently been suggested that an excessive protein diet was specially prone to produce change in the gastro intestinal vessels, so causing 'angina abdominis' In rare instances common salt in excessive quantities had produced œdema in healthy persons, just as it was known to do in nephritis, Rodriguez had recently argued that an excessive intake of salt might, by its influence on metabolism cause some cases of diabetes An excess of carbohydrate food favoured fermentation and in children might cause fever How far an habitual excess of proteins or carbohydrates could, by wearing out the assimilative powers of the tissue, lead to metabolic disorders underlying gout and diabetes was a question which was perhaps hardly within the limits of a discussion on alimentary toxæmia In connexion with this, which was the most obvious aspect of the subject, he would only refer to some rather debatable problems The condition of intestinal infantilism due to chronic diarrhœa might be explained merely as the result of malnutrition Herter and Kendall however, had found that the condition was associated with large numbers of a micro organism (bacillus infantilis) in the stools The suggestion that toxæmia of intestinal origin might produce widespread effects, such as neurasthenia and liability to other infections was in harmony with views put forward by Mr Lane and others It was an attractive hypothesis that changes in the ductless glands either in the direction of proliferative reaction, as in exophthalmic goitre, or of degeneration, as in myxœdema and polyglandular insufficiency, might in certain cases be due to toxins absorbed from the intestine Personally, he quite anticipated that proof would eventually be forthcoming There were some points compatible with the view that exophthalmic goitre might in some instances be the result of alimentary toxæmia Digestive disturbances were very frequent a protein diet usually aggravated the symptoms, indicanuria had in his experience, been common The evidence recently brought by McCarrison to prove that endemic goitre was due to alimentary toxæmia might well suggest that some other form of intestinal toxæmia might induce exophthalmic goitre In both these diseases the blood showed a relative lymphocytosis a change which might be due to intestinal disturbance The relation between synovitis and other forms of arthritis on the one hand, and the alimentary canal on the other hand, provided scope for considerable discussion A E Garrod argued that the transient joint manifestations accompanying erythemas, purpura and urticaria were like the cutaneous changes, toxic The influence of alimentary toxæmia in the production of skin lesions had been fully discussed, and it did not seem unreasonable to suppose that transient attacks of synovitis might be explained similarly The synovitis of acute rheumatism was so transient and left so little or no change that in the presence of the conflicting accounts as to the sterile or infected condition of the joints it might be toxic, and due to the products of streptococci in the alimentary canal The condition of chronic rheumatoid arthritis might be secondary to focal infection in various parts of the alimentary canal. The head retraction and other symptoms of meningism sometimes seen in cases of severe infective diarrhœa in young children appeared to be due to the action of poisons absorbed from the alimentary canal A form of intestinal toxæmia in the new born, due to bacterial infection of the meconium within the first 48 hours, had recently been described by Morse Incomplete evacuation favoured absorption of putrefactive products from the meconium The infant rather suddenly became seriously ill about the third to fifth day, had moderate fever, and commonly cyanosis, twitching, general rigidity, and even convulsions If the

nd

ROYAL SOCIETY OF MEDICINE

SPECIAL MEETING OF FELLOWS

Completed Discussion on Alimentary Toxæmia [1]

A MEETING of the Fellows of this society was held on May 7th Sir FRANCIS H CHAMPNEYS, the President, being in the chair

Dr H D ROLLESTON said that as the uninjured skin was comparatively impervious the other surface covering of the body or the mucous membranes constituted the main inlet for microbes and poisons, and of the various mucous tracts that of the alimentary was much the largest, and further was much the most exposed to infection and intoxication It was true that the exposed condition of the alimentary canal was specially protected by the acid gastric juice against microbic activity and by the liver against poisons, but these lines of defence might be overwhelmed and broken down It was easy to argue that a very large number of the diseases to which flesh was heir were due to intestinal toxæmia but the state of our present knowledge made caution necessary Still, although it might be difficult to prove the widespread influence of alimentary toxæmia it was unwise to put aside possibilities until they could definitely be ruled out A difficulty about a wide assumption as to the existence of alimentary toxæmia in the sense in which it was employed in this discussion—namely effects in other parts of the body due to poisons apart from micro organisms—was that many of the effects assumed to be toxic might be due to the passage of micro organisms in small numbers into the circulation, and so into the tissues The hypothesis of such an escape of micro organisms had long been before us in Adami s sub infection with B coli which he (Adami) suggested played some part in the production of cirrhosis, hæmochromatosis, and pernicious anæmia With the improvements in our methods of blood culture bacteriæmia was now more commonly recognised and in the future transient and comparatively non virulent forms might be found to be more common than was generally realised Another point to be borne in mind in this discussion was that the same result—for example nephritis, neuritis, or arthritis—might be brought about in different ways, by different forms of toxæmia, of which alimentary toxæmia was one Therefore in considering the influence of alimentary toxæmia it was not necessary to argue that it was the exclusive cause of certain conditions The large subject of alimentary toxæmia might be divided in the first place into the results due to (1) alterations in the quality and quantity of the foodstuffs introduced into the intestine, (2) the activity of micro organisms in the intestine To refer in the first place to idiosyncrasies to certain foods it was true that the hypersensitiveness might depend on changes in the blood and tissues the intestine being merely the passive transmitter, but on the other hand the digestive processes might be congenitally so modified or the circumstances so altered by a change of the intestinal flora as to produce poisons out of ordinary food—e g, an abnormal cleavage of proteins and other bodies Thus family periodic paralysis might conceivably be due to a congenital metabolic defect, which in the presence of unsuitable food gave rise to the formation of poisons in the intestine (Gardner) This subject had been discussed by Dr Vaughan Harley, who suggested that the idiosyncrasy of some persons to eggs which was now commonly quoted as an example of anaphylaxis was due to the cleavage of lecithin into cholin which might eventually yield the poisonous body neurin Apart from any active toxic properties alteration in the quality and quantity of the food stuffs might so modify metabolism that morbid changes and symptoms were produced Our knowledge of 'the nutritional importance of the presence in dietaries of minute amounts of certain accessory substances which might possibly activate metabolism was only in its infancy To turn to the more commonplace results of excessive quantities of food, an excess in the intake of proteins was commonly regarded as one of the causes of arteriosclerosis by raising the blood pressure either (1) [illegible] e peripheral field or (2), and [illegible] to later, by primarily acting [illegible] yroid It had recently been suggested that an excessive protein diet was specially prone to produce change in the gastro intestinal vessels, so causing 'angina abdominis' In rare instances common salt in excessive quantities had produced œdema in healthy persons, just as it was known to do in nephritis, Rodriguez had recently argued that an excessive intake of salt might, by its influence on metabolism cause some cases of diabetes An excess of carbohydrate food favoured fermentation and in children might cause fever How far an habitual excess of proteins or carbohydrates could, by wearing out the assimilative powers of the tissue, lead to metabolic disorders underlying gout and diabetes was a question which was perhaps hardly within the limits of a discussion on alimentary toxæmia In connexion with this, which was the most obvious aspect of the subject, he would only refer to some rather debatable problems The condition of intestinal infantilism due to chronic diarrhœa might be explained merely as the result of malnutrition Herter and Kendall however, had found that the condition was associated with large numbers of a micro organism (bacillus infantilis) in the stools The suggestion that toxæmia of intestinal origin might produce widespread effects, such as neurasthenia and liability to other infections was in harmony with views put forward by Mr Lane and others It was an attractive hypothesis that changes in the ductless glands either in the direction of proliferative reaction, as in exophthalmic goitre, or of degeneration, as in myxœdema and polyglandular insufficiency, might in certain cases be due to toxins absorbed from the intestine Personally, he quite anticipated that proof would eventually be forthcoming There were some points compatible with the view that exophthalmic goitre might in some instances be the result of alimentary toxæmia Digestive disturbances were very frequent a protein diet usually aggravated the symptoms, indicanuria had in his experience, been common The evidence recently brought by McCarrison to prove that endemic goitre was due to alimentary toxæmia might well suggest that some other form of intestinal toxæmia might induce exophthalmic goitre In both these diseases the blood showed a relative lymphocytosis a change which might be due to intestinal disturbance The relation between synovitis and other forms of arthritis on the one hand, and the alimentary canal on the other hand, provided scope for considerable discussion A E Garrod argued that the transient joint manifestations accompanying erythemas, purpura and urticaria were like the cutaneous changes, toxic The influence of alimentary toxæmia in the production of skin lesions had been fully discussed, and it did not seem unreasonable to suppose that transient attacks of synovitis might be explained similarly The synovitis of acute rheumatism was so transient and left so little or no change that in the presence of the conflicting accounts as to the sterile or infected condition of the joints it might be toxic, and due to the products of streptococci in the alimentary canal The condition of chronic rheumatoid arthritis might be secondary to focal infection in various parts of the alimentary canal. The head retraction and other symptoms of meningism sometimes seen in cases of severe infective diarrhœa in young children appeared to be due to the action of poisons absorbed from the alimentary canal A form of intestinal toxæmia in the new born, due to bacterial infection of the meconium within the first 48 hours, had recently been described by Morse Incomplete evacuation favoured absorption of putrefactive products from the meconium The infant rather suddenly became seriously ill about the third to fifth day, had moderate fever, and commonly cyanosis, twitching, general rigidity, and even convulsions If the [illegible] nd [illegible] te [illegible] irb [illegible] metabolism were various and as illustrating the complexity of the subject Woolley and Newburgh s explanation of the etiology of diabetes might be quoted As they found that the injection of indol produced hypertrophy of the medulla of the suprarenals, they suggested that such hypertrophy, if but its use without proper differentiation had caused disappointment just as a similar misuse of the "sour milk" and "Salisbury" treatments had greatly damaged those valuable methods in the eyes of our profession Those somewhat rare but most intractable cases of recurrent acute erysipelatous eczema had never in his experience failed to respond to thorough intestinal lavage Many other chronic and refractory cases of various kinds, but all possessing one feature—viz , marked excess of aromatic sulphates in the urine—had responded readily to this treatment He concluded by drawing attention to three general methods which he had found of the utmost value in all alimentary toxæmias (a) The administration of a strong solution of radium emanations in water Lazarus Saubermann, Deutelmoser, Berger, Bickel, and many others had shown that these emanations (1) greatly increased the activity of the various ferments, especially the peptonic and diastatic, (2) markedly improved nerve vitality, especially of the sympathetic system, (3) stimulated the output of the body waste, the carbon dioxide from the lungs by 20 to 60 per cent, the sweat toxins by 40 to 70 per cent, the urinary poisons by 10 to 15 per cent , (4) had a destructive influence, in large doses, over low forms of bacterial and spore life (b) The use of oxygen, either inhaled in association with radium emanation, or given in the bath by the double powder of sodium perborate and manganese borate (c) Professor Bergonié's method of strong, rapid, painless, simultaneous contraction of practically the whole of the muscles which were weighted to increase the contractions He had found that this method, originally introduced for the rational treatment of obesity (in which it had proved most effective), was most helpful in alimentary toxæmia It braced up the abdominal walls and also the atonic intestinal canal, it emptied the lymph spaces between the muscles and quickened the often stagnant lymph circulation, stimulated the whole nervous system, and speedily dissipated those feelings of malaise and misery which made the life of the sufferer from alimentary toxæmia so wretched, paving the way if allowed to go unchecked for that most intractable form of neurasthenia which was at once the despair of, and a reproach to, our profession

---

[1] THE LANCET March 15th (p 754) April 19th (p 1093) and 26th (p 1163) and May 3rd (p 1237) and 10th (p 1310) 1913

Dr W KNOWSLEY SIBLEY, speaking of alimentary toxæmia in dermatology, said that a very large number of skin eruptions were the external manifestations of a morbid condition of the general system directly due to a toxæmia of the blood, the result of the absorption of morbid products from the gastro intestinal tract It followed that in all of these conditions proper attention not only to the diet or intake, but also to the excreta or output, was of primary importance for the satisfactory treatment of the skin complaint A system saturated with the toxins absorbed from an overloaded intestine was by no means an uncommon cause of a large number of apparently very different skin diseases In fact, it would be difficult in the present state of our knowledge to name many manifestations (excluding, of course, the various parasitic diseases, both animal and vegetable) which were not in many cases the external expression of a general unhealthy condition of the blood supplying the region, the result of a defective assimilation of the digestive processes, or more generally of a delayed excretion of the waste products of the digestive metabolism The first sign of a want of balance between assimilation and excretion was usually to be found in the colour and condition of the skin, especially in certain regions of the body A pasty or muddy complexion often was one of the signs of malassimilation, or of absorption from the contents of the large bowel or both The results of so called hepatic derangements showed themselves very quickly in the colour of the skin, and pointed to digestive disturbances of various degrees A large group of skin phenomena under the heading of urticarias or nettle rashes had long been recognised as the direct result of gastro-intestinal influences and were designated "stomach rashes" Many other common diseases, both acute and chronic, were also determined by similar processes There was no doubt that the condition of the gastro intestinal tract played a leading part in a large number of cases of eczema, and that proper attention to the regulation of the diet and of the bowels was necessary for their satisfactory treatment Psoriasis, again, was often undoubtedly the result of toxic influences derived from the gastro intestinal tract, and a complete change in the diet from a too nitrogenous to a vegetarian one would often cure an old standing case So again, acne in its various forms was generally associated with an overloaded bowel, and free purgation was often the most efficient treatment, the same might be said of many cases of purpura. Even in many diseases, obviously due to the invasion of micro organisms, such as staphylococci, streptococci, or perhaps even the acne bacillus a toxic condition of the blood due to a systemic poisoning from fæcal or other morbid absorption was necessary for the growth and development of these organisms From his experience he should say that, speaking generally, the immunity of the skin to the development of micro organisms was directly impaired by an obstructed drainage system It was evident that in a large number of cases of general skin diseases it was the mucous membrane rather than the skin which required the chief attention The skin lesion might be controlled and rendered more comfortable by suitable local more or less sedative, protective or bland applications, but it was to the gastro intestinal tract that the main treatment should be directed In every case of skin eruption a systematic examination of this should be made before determining the special line of treatment The whole systemic disturbance might be due to a neglected pyorrhœa alveolaris and to absorption from it either locally or from the stomach after being swallowed and setting up a gastro intestinal catarrh He had discussed the relation between pyorrhœa alveolaris and certain diseases of the skin in a paper read before the Odontological Section of this society two years ago, in which he enumerated a large number of different eruptions that could often be traced to pyorrhœa, and indicated the part it played in alimentary toxæmia, and the treatment for which eruptions was to be directed mainly to the cure of pyorrhœa Some of the diseases he then enumerated were acne vulgaris and rosacea, alopecia (and especially alopecia areata), eczema, erythema, herpes, œdema, seborrhœa, and seborrhœic eczema Leaving the oral cavity and passing on to consider the stomach, there might be a chronic gastritis due to errors of diet, especially from the abuse of alcohol, producing a catarrhal condition affecting not only the stomach but also the hepatic system, and extending its baneful influences on into the duodenum and small intestines More frequently still the colon was found to be loaded with old standing fæcal accumulations, gradual absorption from which produced a general systemic poisoning To sum up, the treatment of a large number of general skin eruptions resolved itself into the scientific treatment of chronic constipation With regard to this most important fact in dermatology, it had to be realised that because a patient had a daily evacuation of the bowels it by no means necessarily followed that he did not suffer from all the morbid effects of toxic absorption from an overloaded colon It was not the frequency of evacuation that was of importance but the quantity, that is to say, that the contents of the large bowel were systematically completely removed, and that there was not an ever increasing residue left behind In other words, it was necessary to be sure that the patient was not passing to day what he ought to have got rid of a week, or perhaps a month, ago He had often remarked that most, if not all, of the drugs which had been found of benefit in the treatment of general diseases of the skin acted chiefly, if not entirely, as laxatives, aperients, or disinfectants of the gastro intestinal tract, and he believed their beneficial effect was due to their direct local action on the gastro intestinal contents rather than to any specific action of the preparations themselves The most popular drug with the older school of dermatologists was arsenic, which was often prescribed as a specific for most of the more or less chronic forms of skin diseases Arsenical preparations were among the most powerful bactericidal agents known to chemists, and, apart from their irritating, and therefore laxative, effects in the mucous membranes it was to this property that their so-called specific action was probably due Mercury, a specific for other skin diseases than those produced by syphilis, was essentially a most powerful germ destroyer Quinine in solution was also a powerful bactericidal agent and disinfectant, and was equally efficacious for this purpose when administered into the stomach or when used for washing out the bladder or other viscus Perhaps the next most popular drug and one which still held its place, was iodide of potassium; and here, again, iodine was now but its use without proper differentiation had caused disappointment just as a similar misuse of the "sour milk" and "Salisbury" treatments had greatly damaged those valuable methods in the eyes of our profession. Those somewhat rare but most intractable cases of recurrent acute erysipelatous eczema had never in his experience failed to respond to thorough intestinal lavage. Many other chronic and refractory cases of various kinds, but all possessing one feature—viz., marked excess of aromatic sulphates in the urine—had responded readily to this treatment. He concluded by drawing attention to three general methods which he had found of the utmost value in all alimentary toxæmias. (a) The administration of a strong solution of radium emanations in water. Lazarus Saubermann, Deutelmoser, Berger, Bickel, and many others had shown that these emanations (1) greatly increased the activity of the various ferments, especially the peptonic and diastatic; (2) markedly improved nerve vitality, especially of the sympathetic system; (3) stimulated the output of the body waste, the carbon dioxide from the lungs by 20 to 60 per cent., the sweat toxins by 40 to 70 per cent., the urinary poisons by 10 to 15 per cent.; (4) had a destructive influence, in large doses, over low forms of bacterial and spore life. (b) The use of oxygen, either inhaled in association with radium emanation, or given in the bath by the double powder of sodium perborate and manganese borate. (c) Professor Bergonié's method of strong, rapid, painless, simultaneous contraction of practically the whole of the muscles which were weighted to increase the contractions. He had found that this method, originally introduced for the rational treatment of obesity (in which it had proved most effective), was most helpful in alimentary toxæmia. It braced up the abdominal walls and also the atonic intestinal canal; it emptied the lymph spaces between the muscles and quickened the often stagnant lymph circulation, stimulated the whole nervous system, and speedily dissipated those feelings of malaise and misery which made the life of the sufferer from alimentary toxæmia so wretched, paving the way if allowed to go unchecked for that most intractable form of neurasthenia which was at once the despair of, and a reproach to, our profession.

Dr. W. Knowsley Sibley, speaking of alimentary toxæmia in dermatology, said that a very large number of skin eruptions were the external manifestations of a morbid condition of the general system directly due to a toxæmia of the blood, the result of the absorption of morbid products from the gastro-intestinal tract. It followed that in all of these conditions proper attention not only to the diet or intake, but also to the excreta or output, was of primary importance for the satisfactory treatment of the skin complaint. A system saturated with the toxins absorbed from an overloaded intestine was by no means an uncommon cause of a large number of apparently very different skin diseases. In fact, it would be difficult in the present state of our knowledge to name many manifestations (excluding, of course, the various parasitic diseases, both animal and vegetable) which were not in many cases the external expression of a general unhealthy condition of the blood supplying the region, the result of a defective assimilation of the digestive processes, or more generally of a delayed excretion of the waste products of the digestive metabolism. The first sign of a want of balance between assimilation and excretion was usually to be found in the colour and condition of the skin, especially in certain regions of the body. A pasty or muddy complexion often was one of the signs of malassimilation, or of absorption from the contents of the large bowel or both. The results of so-called hepatic derangements showed themselves very quickly in the colour of the skin, and pointed to digestive disturbances of various degrees. A large group of skin phenomena under the heading of urticarias or nettle rashes had long been recognised as the direct result of gastro-intestinal influences and were designated "stomach rashes." Many other common diseases, both acute and chronic, were also determined by similar processes. There was no doubt that the condition of the gastro-intestinal tract played a leading part in a large number of cases of eczema, and that proper attention to the regulation of the diet and of the bowels was necessary for their satisfactory treatment. Psoriasis, again, was often undoubtedly the result of toxic influences derived from the gastro-intestinal tract, and a complete change in the diet from a too nitrogenous to a vegetarian one would often cure an old-standing case. So again, acne in its various forms was generally associated with an overloaded bowel, and free purgation was often the most efficient treatment; the same might be said of many cases of purpura. Even in many diseases, obviously due to the invasion of micro-organisms, such as staphylococci, streptococci, or perhaps even the acne bacillus, a toxic condition of the blood due to a systemic poisoning from fæcal or other morbid absorption was necessary for the growth and development of these organisms. From his experience he should say that, speaking generally, the immunity of the skin to the development of micro-organisms was directly impaired by an obstructed drainage system. It was evident that in a large number of cases of general skin diseases it was the mucous membrane rather than the skin which required the chief attention. The skin lesion might be controlled and rendered more comfortable by suitable local more or less sedative, protective or bland applications, but it was to the gastro-intestinal tract that the main treatment should be directed. In every case of skin eruption a systematic examination of this should be made before determining the special line of treatment. The whole systemic disturbance might be due to a neglected pyorrhœa alveolaris and to absorption from it either locally or from the stomach after being swallowed and setting up a gastro-intestinal catarrh. He had discussed the relation between pyorrhœa alveolaris and certain diseases of the skin in a paper read before the Odontological Section of this society two years ago, in which he enumerated a large number of different eruptions that could often be traced to pyorrhœa, and indicated the part it played in alimentary toxæmia, and the treatment for which eruptions was to be directed mainly to the cure of pyorrhœa. Some of the diseases he then enumerated were acne vulgaris and rosacea, alopecia (and especially alopecia areata), eczema, erythema, herpes, œdema, seborrhœa, and seborrhœic eczema. Leaving the oral cavity and passing on to consider the stomach, there might be a chronic gastritis due to errors of diet, especially from the abuse of alcohol, producing a catarrhal condition affecting not only the stomach but also the hepatic system, and extending its baneful influences on into the duodenum and small intestines. More frequently still the colon was found to be loaded with old-standing fæcal accumulations, gradual absorption from which produced a general systemic poisoning. To sum up, the treatment of a large number of general skin eruptions resolved itself into the scientific treatment of chronic constipation. With regard to this most important fact in dermatology, it had to be realised that because a patient had a daily evacuation of the bowels it by no means necessarily followed that he did not suffer from all the morbid effects of toxic absorption from an overloaded colon. It was not the frequency of evacuation that was of importance but the quantity; that is to say, that the contents of the large bowel were systematically completely removed, and that there was not an ever-increasing residue left behind. In other words, it was necessary to be sure that the patient was not passing to-day what he ought to have got rid of a week, or perhaps a month, ago. He had often remarked that most, if not all, of the drugs which had been found of benefit in the treatment of general diseases of the skin acted chiefly, if not entirely, as laxatives, aperients, or disinfectants of the gastro-intestinal tract, and he believed their beneficial effect was due to their direct local action on the gastro-intestinal contents rather than to any specific action of the preparations themselves. The most popular drug with the older school of dermatologists was arsenic, which was often prescribed as a specific for most of the more or less chronic forms of skin diseases. Arsenical preparations were among the most powerful bactericidal agents known to chemists, and, apart from their irritating, and therefore laxative, effects in the mucous membranes it was to this property that their so-called specific action was probably due. Mercury, a specific for other skin diseases than those produced by syphilis, was essentially a most powerful germ destroyer. Quinine in solution was also a powerful bactericidal agent and disinfectant, and was equally efficacious for this purpose when administered into the stomach or when used for washing out the bladder or other viscus. Perhaps the next most popular drug and one which still held its place, was iodide of potassium; and here, again, iodine was now of the simplified individual, which speaks for itself. The tempting notion of the easy accidental ingress into *the circulating blood of microbes not gifted with intrinsic* powers of penetration is a delusion. Their insertion by trauma into the venules is another matter—a remark that applies to the occasional ingress through abraded or degenerated mucous membrane into the meningo-faucial lymphatic sheaths. Imperfect phagocytosis and subsequent disgorgement in the deeper tissue interspaces is a more common and consequential occurrence. Such liberated organisms would set up thickenings in those situations according to their toxicity, without necessarily leaving any trace of their existence. They could not be recovered and cultivated. Toxins that are ingested into the portal blood may be discharged in the bile or then be modified, and, if not discharged by the lungs or the skin, would eventually be discharged by the kidneys. Failing these emunctory channels, and depending upon the relative viscosity of the fluids within and without the blood-vessels, certain toxic molecular complexes are constantly escaping by diffusion into the lymph. It is to meet this danger that the inception of endarteritis, periarteritis, and sclerosis takes place. It is owing to this liability to escape from the blood during excretory transit and to no other cause. I have endeavoured to fasten attention on this question of the lymphatics during the past few years. The more I have studied them the more is this truth borne in upon me, and the more I am concerned to *champion in my humble way their important rôle in the* mechanisms of disease. Like the indispensable foreign secretary, how many wars has he nipped in the bud by his successful diplomacy carried on over a long period of years, and of which the public are left, by his very success, in entire ignorance? *Credidi—quod propter locutus sum.*

Dr. RALPH VINCENT dealt with the bacteriology of alimentary toxæmia in the infant and child. His classification of the organisms was based upon their growth in and their action upon milk. The four groups were: (1) bacteria producing lactic acid but not producing gas; (2) bacteria producing lactic acid, carbon dioxide, and alcohol; (3) bacteria growing in "pasteurised" milk; and (4) bacteria growing in boiled or "sterilised" milk With regard to the bacteriological analysis of the intestinal dejecta three classes of organisms were commonly observed: (1) obligatory fermentative bacteria; (2) facultative fermentative bacteria; and (3) obligatory proteolytic bacteria. He then discussed the biochemical processes occurring in the alimentary canal of the [illegible] colon toxæmia.

SURGICAL SECTION.

Aberrant Renal Arteries.—Splenectomy.

A MEETING of this section was held on May 6th, Mr. G. H. MAKINS, the President, being in the chair.

Mr. J. HUTCHINSON read a paper on Obstruction of the Ureter by Aberrant Renal Vessels. This was a clinical study of 21 cases operated upon by the surgeons of the London Hospital during the last eight years. The presence of a "tail-artery" (that is, one running from the aorta or renal trunk to the lower pole of the kidney and crossing the ureter), being a congenital condition, would be expected to cause trouble in the first few years. It did so, however, but rarely, the first attack of lumbar or abdominal pain due to obstruction of the ureter coming on in two-thirds of the cases between the ages of 15 and 25 years, very rarely before this. The cases were twice as common in males as in females, and the right kidney was concerned twice as frequently as the left, to judge from the present series. The aberrant artery, accompanied or not by a vein, crossed behind the ureter as a rule; the obstruction due to it had little or no relation to the kidney becoming mobile or floating. The attacks of pain produced by distension of the pelvis were severe, of sudden onset, often attended with vomiting and sweating; the act of vomiting relieved the pain. These attacks were separated at first by months or years, but became more and more frequent, e.g., every few days; they always lasted some hours. Exercise had little relation to the attacks, which might come on when the patient was lying down. Diet and medicines had no effect upon them; heat applied to the loin and rest *on the affected side* usually relieved. An important point was that there were no urinary symptoms in these cases, and it was probably this that led to the long delay in recognising their nature. In most of the cases brought forward the patient had endured the attacks for several years before obtaining surgical relief. It was essential to operate by lumbar incision before permanent hydronephrosis had been established and the kidney had become disorganised. The aberrant artery should be divided, and the kinked (often much distorted) ureter and pelvis straightened out. From the evidence of cases up to the present time it was not advisable to attempt any form of plastic operation upon the pelvis and ureter, as suppuration and escape of urine were certain to spoil the result. Nephrectomy was necessary in about one-fifth of the series. If the kidney were found too mobile it should be anchored in place after division of the aberrant vessels. Attention was especially drawn to the question of diagnosis of the condition, and a detailed account of the symptoms, &c., was given. Now that the X rays enabled renal calculus to be detected easily the difficulty should be much lessened. The slight resemblance to appendicitis attacks might lead to removal of the appendix, but a lumbar exploration of the kidney should be resorted to in every suspicious case.

Mr. FRANK KIDD showed two cases of Enlarged Spleen Cured by Splenectomy. 1. "*Banti's disease*," or "*splenic anæmia*." This case was that of a girl referred by Sir Bertrand Dawson. She was aged 17 years at the onset, and was operated on in the third stage of the disease, two years after the onset. She showed all the classical signs of the disease: enlarged spleen, secondary anæmia, pigmentation of skin, leukopenia, periodic gastric hæmorrhages, ascites, œdema of legs, small cirrhotic liver, and wasting (3 st.). There was an absence of syphilitic or alcoholic history. The operation proved difficult owing to adventitious adhesions containing enormously dilated veins, which tore easily, but the spleen was successfully removed through a 5-in. vertical incision through the left rectus muscle. The result, seven months later, was that pigmentation and anæmia were gone; there was no ascites or œdema; the blood-count was normal, save for a slight lymphocytosis; the scar was sound. The patient never felt better in her life. A chart was shown of a series of blood-counts made before and after removal of the spleen. Mr. Kidd shortly reviewed the history of the clinical conception of "Banti's disease," and brought forward some post-mortem evidence to show that the symptom-complex could be brought about by more than one cause. The constant cause appeared to be anything which could produce engorgement or obstruction of the portal venous system. Seeing the extraordinary amelioration of symptoms brought about by splenectomy in many of these cases, Mr. Kidd suggested that a trial of splenectomy ought certainly to be made in all cases of cirrhosis of the liver with enlarged spleen. It seemed possible that it was the enlarged spleen which caused the fatal symptoms in cirrhosis of the liver, and its removal in alcoholic cirrhosis might lead to results as brilliant as in the case recorded above. The operation was not more dangerous than omentopexy if a large enough incision were made so as to ensure proper exposure and easy control of deeply placed bleeding points. 2. A woman, referred by Dr. S. M. Mackenzie, of Dorking, who had suffered for six months with attacks of severe pain in the left hypochondrium, the last of which had ended in an attack of peritonitis, since which time the patient had noticed a dragging pain in the left shoulder-joint. A large tumour was found in the left hypochondrium. To exclude renal tumour a ureteric catheter was passed up the left ureter, and the kidney filled with collargol, and skiagraphed. The shadow of the kidney, its pelvis, and the ureter was normal. Operation was as follows. The abdomen was explored through the left rectus. A large spleen was found densely adherent to the diaphragm and removed. The microscopical diagnosis was hypertrophy of the spleen. Convalescence was marred by an attack of broncho-pneumonia at the left lung base, but the wound healed by first intention, and a year later the patient was reported by her medical attendant as being quite well. This was a case of hypertrophy of the spleen. Laspeyres had collected 16 cases where operation had been performed for such a condition. In this case the hypertrophy was the primary factor, followed by attacks of rotation of the pedicle. The last of these attacks ended of the simplified individual, which speaks for itself. The tempting notion of the easy accidental ingress into the circulating blood of microbes not gifted with intrinsic powers of penetration is a delusion. Their insertion by trauma into the venules is another matter—a remark that applies to the occasional ingress through abraded or degenerated mucous membrane into the meningo-faucial lymphatic sheaths. Imperfect phagocytosis and subsequent disgorgement in the deeper tissue interspaces is a more common and consequential occurrence. Such liberated organisms would set up thickenings in those situations according to their toxicity, without necessarily leaving any trace of their existence. They could not be recovered and cultivated. Toxins that are ingested into the portal blood may be discharged in the bile or then be modified, and, if not discharged by the lungs or the skin, would eventually be discharged by the kidneys. Failing these emunctory channels, and depending upon the relative viscosity of the fluids within and without the blood-vessels, certain toxic molecular complexes are constantly escaping by diffusion into the lymph. SECTION OF OBSTETRICS

Congenital Cystic Tumour —Clinical Report of the Rotunda Hospital

A MEETING of this section was held on April 18th Dr R D PUREFOY being in the chair

Mr T SPENCER SHEILL exhibited a photograph demonstrating a Congenital Cystic Tumour in an infant situated in the mammary line on the right side After two months as there were no signs of subsidence he withdrew 1 oz of serous fluid with a trocar It again filled up and he *proposed to open the tumour and treat it as an open* wound He gave details of a similar former case —Dr PUREFOY said he was sure Mr Sheill was correct in looking on this as an uncommon form of tumour

Dr H JELLETT read the clinical report of the Rotunda Hospital for the year ending Oct 31st 1912 The report showed that during the year 2339 patients were delivered under the care of the hospital extern department, and 2474 patients were admitted to the maternity wards Of the latter number 338 who were not in labour were discharged undelivered and 2136 were delivered Thus a total of 4475 labours in all were attended by the hospital staff being an increase of 26 on the previous year Ten deaths occurred in the extern department and 11 in the intern being a percentage mortality of 0 42 in the former and of 0 46 in the latter, or a mean percentage mortality of 0 44 The principal event of the year was the opening of the new labour wards. There was a violent outbreak of sepsis from which two patients died, nevertheless, the morbidity rate was lower than the previous year and was represented by 5 53 per cent as against 6 64 During the past year there was no change in the plan of allowing patients out of bed much earlier than was generally held advisable, which had proved most satisfactory and beneficial to the patients The report then dealt with the different complications of labour met with during the year There were 7 cases of unavoidable hæmorrhage in 4 of which the placenta was situated centrally over the cervix In all cases the mother recovered The routine treatment of Braxton Hicks's bipolar version was adopted There was one case of accidental hæmorrhage successfully treated by plugging the vagina There were 24 cases of contracted pelvis in 8 of which delivery was spontaneous in 3 the forceps was applied and in 3 pubiotomy in 4 Cæsarean section and in 4 craniotomy was done In the craniotomy cases the child was dead so no other method of delivery was tried All the mothers recovered There were 10 cases of prolapse and presentation of the cord which were treated in different ways All the mothers recovered and 5 children were born alive There were 14 cases of eclampsia some of a very severe type Twelve mothers recovered and two died The forceps was applied on 79 occasions One mother died as a result of hyperemesis from which she had been suffering for some time Sixty nine children were born alive and 10 dead There were 5 cases of Cæsarean section All the mothers recovered and all the children who were alive when the operation was undertaken were delivered alive One child was delivered dead and putrid as the mother had been for a considerable time in labour before admission There were three cases of pubiotomy in all of which the mothers recovered and the children were delivered alive There was one radical Cæsarean section and one complete hysterectomy to effect delivery in the case of a myomatous uterus Both these patients were septic before operation The case of myoma died on the sixth day the other patient recovered rapidly Particular attention was drawn to the introduction during the year of the operation of excision of thrombosed veins in case of pyæmia During the year 587 patients were

9—i e , 1 87 per cent Of the 9 deaths one occurred the day after admission in a case of incarcerated myoma which had been causing retention of urine for a considerable time The inside of the bladder was gangrenous the urine black and foul smelling and the patient was in a condition of general poisoning One death was from recurrent ovarian papilloma one from carcinoma of the pylorus one from sarcoma of the uterus necessitating extensive intestinal resection one *from chorion epithelioma one from heart failure* after an operation for prolapsus uteri one from acute general peritonitis after operation for tubercular appendages and one in a patient admitted seven months pregnant with high temperature and rapid pulse who became jaundiced with total suppression of urine Hysterectomy for malignant disease was almost the only major operation in which the figures were lower than the previous year The number of operations for myomata was considerable There were 15 *hysterectomies all supravaginal and 24 myomectomies In* a large proportion of cases it was found possible to save the uterus All these cases both hysterectomy and myomectomy recovered Twenty five operations were performed for *prolapse* Wertheim's interposition operation was done in 18 cases Dr Jellett's operation for shortening of the utero sacral ligaments was done in 13 cases in six of which the interposition operation was also performed —Dr PUREFOY thought many of the fatal cases of accidental hæmorrhage were due to the fact that accidental hæmorrhage was met with in patients with organic disease who were badly able to stand the shock attending the hæmorrhage He thought that in these cases vaginal tampons might be left in a little longer He considered that one of the greatest risks and most serious mistakes was undue anxiety to empty the uterus quickly and before the patient had time to rally from the hæmorrhage With regard to the introduction of early rising of patients after their confinement he was by no means convinced from what *he had heard that the* practice was to be recommended nor did he consider the fact that no accidents had been reported in the cases treated as sufficient argument in favour of it He suggested that the treatment might in future produce a number of patients suffering from misplacements, &c It was very interesting the body The two varieties in the dog—the sarcoptis canis a parasite of the usual itch order and the demodex folliculorum—had each its analogue in the human species Both were contagious to man The sarcoptis canis was most virulent in the dog an animal badly affected lost all its hair and had a very offensive smell Cure was difficult and often impossible In sarcoptic mange the dog persistently scratched especially under the forelegs and thighs and when in front of the fire or in a warm room could not keep still If neglected the coat fell off the skin became covered with blood stained scabs and there was a peculiar mousy ' odour Infections and reinfections of the owners of pet dogs and cats by the sarcoptic parasite were common but although the facts were well known the transmission of the parasite was not suspected so often as it ought *to be Lastly ringworm as seen in the horse calf dog and* cat was considered The varieties most commonly met with were ordinary ringworm (tinea tonsurans) and the honeycomb ringworm (tinea favosa) both contagious for man In the country ringworm of calves was common In animals the disease was tolerably easy to cure the best remedies being either tincture of iodine or the alcoholic solution of salicylic acid (Professor Hobday s remarks were well illustrated by numerous lantern slides and pictures)

Congenital Cystic Tumour —Clinical Report of the Rotunda Hospital

A meeting of this section was held on April 18th Dr R D Purefoy being in the chair

Mr J Spencer Sheill exhibited a photograph demonstrating a Congenital Cystic Tumour in an infant situated in the mammary line on the right side After two months as there were no signs of subsidence he withdrew 1 oz of serous fluid with a trocar It again filled up and he *proposed to open the tumour and treat it as an open* wound He gave details of a similar former case —Dr Purefoy said he was sure Mr Sheill was correct in looking on this as an uncommon form of tumour

Dr H Jellett read the clinical report of the Rotunda Hospital for the year ending Oct 31st 1912 The report showed that during the year 2339 patients were delivered under the care of the hospital extern department, and 2474 patients were admitted to the maternity wards Of the latter number 338 who were not in labour were discharged undelivered and 2136 were delivered Thus a total of 4475 labours in all were attended by the hospital staff being an increase of 26 on the previous year Ten deaths occurred in the extern department and 11 in the intern being a percentage mortality of 0 42 in the former and of 0 46 in the latter, or a mean percentage mortality of 0 44 The principal event of the year was the opening of the new labour wards. There was a violent outbreak of sepsis from which two patients died, nevertheless, the morbidity rate was lower than the previous year and was represented by 5 53 per cent as against 6 64 During the past year there was no change in the plan of allowing patients out of bed much earlier than was generally held advisable, which had proved most satisfactory and beneficial to the patients The report then dealt with the different complications of labour met with during the year There were 7 cases of unavoidable hæmorrhage in 4 of which *the* placenta was situated centrally over the cervix In all cases the mother recovered The routine treatment of Braxton Hicks's bipolar version was adopted There was one case of accidental hæmorrhage successfully treated by plugging the vagina There were 24 cases of contracted pelvis in 8 of which delivery was spontaneous in 3 the forceps was applied and in 3 pubiotomy in 4 Cæsarean section and in 4 craniotomy was done In the craniotomy cases the child was dead so no other method of delivery was tried All the mothers recovered There were 10 cases of prolapse and presentation of the cord which were treated in different ways All the mothers recovered and 5 children were born alive There were 14 cases of eclampsia some of a very severe type Twelve mothers recovered and two died The forceps was applied on 79 occasions One mother died as a result of hyperemesis from which she had been suffering for some time Sixty nine children were born alive and 10 dead There were 5 cases of Cæsarean section All the mothers recovered and all the children who were alive when the operation was undertaken were delivered alive One child was delivered dead and putrid as the mother had been for a considerable time in labour before admission There were three cases of pubiotomy in all of which the mothers recovered and the children were delivered alive There was one radical Cæsarean section and one complete hysterectomy to effect delivery in the case of a myomatous uterus Both these patients were septic before operation The case of myoma died on the sixth day the other patient recovered rapidly Particular attention was drawn to the introduction during the year of the operation of excision of thrombosed veins in case of pyæmia During the year 587 patients were

9—i e , 1 87 per cent Of the 9 deaths one occurred the day after admission in a case of incarcerated myoma which had been causing retention of urine for a considerable time The inside of the bladder was gangrenous the urine black and foul smelling and the patient was in a condition of general poisoning One death was from recurrent ovarian papilloma one from carcinoma of the pylorus one from sarcoma of the uterus necessitating extensive intestinal resection one *from chorion epithelioma one from heart failure* after an operation for prolapsus uteri one from acute general peritonitis after operation for tubercular appendages and one in a patient admitted seven months pregnant with high temperature and rapid pulse who became jaundiced with total suppression of urine Hysterectomy for malignant disease was almost the only major operation in which the figures were lower than the previous year The number of operations for myomata was considerable There were 15 *hysterectomies all supravaginal and 24 myomectomies In* a large proportion of cases it was found possible to save the uterus All these cases both hysterectomy and myomectomy recovered Twenty five operations were performed for *prolapse* Wertheim s interposition operation was done in 18 cases Dr Jellett s operation for shortening of the utero sacral ligaments was done in 13 cases in six of which the interposition operation was also performed —Dr Purefoy thought many of the fatal cases of accidental hæmorrhage were due to the fact that accidental hæmorrhage was met with in patients with organic disease who were badly able to stand the shock attending the hæmorrhage He thought that in these cases vaginal tampons might be left in a little longer He considered that one of the greatest risks and most serious mistakes was undue anxiety to empty the uterus quickly and before the patient had time to rally from the hæmorrhage With regard to the introduction of early rising of patients after their confinement he was by no means convinced from what *he had heard that the* practice was to be recommended nor did he consider the fact that no accidents had been reported in the cases treated as sufficient argument in favour of it He suggested that the treatment might in future produce a number of patients suffering from misplacements, &c It was very interesting with an unrelated healthy individual has always resulted in the offspring being all apparently healthy An elaborate genealogical table is given in the second volume, showing the probable descent of the abnormality from one of the parents of the original forefather of the stock, in which it appears that half the children of the forefather carried the concealed abnormality and half were completely free from it, as would be theoretically expected

Dementia præcox also showed itself with abnormal frequency in the "great family," there being 68 cases, and besides these there were 15 peculiar members who were not improbably slight examples of dementia præcox The author supports with considerable probability of correctness the view of Rudin, of Munich that this form of insanity is a Mendelian recessive In the same way he regards paralysis agitans, of which seven certain and two uncertain cases appeared in the family, as a Mendelian recessive, but naturally with a disease which appears so late in life the evidence in favour of this is much weaker than in the conditions previously mentioned

There was also an abnormal proportion of feeble mindedness amongst the members of the "great family" Dr Lundborg wisely refrains from discussing the heredity of this ill defined condition, which has been regarded as a Mendelian dominant, and the facts he adduces do not add much to our knowledge of the subject Though the author is evidently a believer in Mendelism he apparently also considers that abnormal traits may be gradually eliminated out of the race by marriage with better equipped persons, presumably by a process of blending In breeding was very frequent in the family, and he remarks on the improvement that has apparently taken place in the branches whose ancestors have emigrated and married abroad But recessive traits would not be expected to appear in these circumstances, though still present in a proportion of the children, and there is also the possibility that those persons who had the energy and initiative to escape from the district were on the whole the best specimens of the race

The original founder of the stock was a well to do farmer, and in the earlier generations a few decidedly gifted individuals appeared The family as a whole seems to have gone downhill since then Very few of its members entered the secondary schools, and as a rule their intelligence seems to have been decidedly below the normal The modern representatives are also in a lower social position than their forebears The fecundity of the women was remarkable, and it is also striking that the death rate was lower than the usual death rate in the surrounding population Naturally where the parents were drunkards or bad characters there was a high infantile mortality

In congratulating the author on the completion of this the most important piece of work of its kind, we can re echo his appeal for further research on the same lines There is a natural tendency to investigate only those families in which some striking abnormality appears, and for the moment perhaps the most valuable results are to be obtained from these It is important that as early as possible some agreement should be arrived at as to what are the signs of "degeneration" in human beings, and that such adjectives as "feeble minded" and "neuropathic" should have a definite and precise meaning In the study of human heredity it is essential that every individual of the family should, as here be characterised, and even the miscarriages recorded On the other hand as Dr Lundborg points out, normal breeds would also repay investigation, and a fruitful field of research is here opened up to the medical practitioner, particularly in isolated country districts In this as in other branches of scientific work central organisation and assistance are required We in England can express our envious admiration of the generous help afforded Dr Lundborg in his expensive and arduous task, though the financial part of the assistance fell far short of his actual disbursements No expense seems to have been spared in the publication perhaps to the chagrin of future readers, since the size and weight of the volumes make them very uncomfortable to handle, while the price, £6, renders them inaccessible to many students of the subject, which is very unfortunate

The Family History Book By C B DAVENPORT September, 1912 Bulletin 7 Price 50 cents Pp 101

THE above are the publications of the Eugenics Record Office, Cold Spring Harbour N Y, and are arranged as Memoirs and Bulletins We are apt to regard a family as a small unit which in itself can have little effect on the community as a whole Nevertheless, this view may be quite erroneous, since it has been clearly shown that by the multiplication of one stock or of two of similar type which intermarry, the social conditions of a whole district may be determined In the neighbourhood of a small town which lies "in a fertile river valley among the New England hills" lives a population among whom feeblemindedness immorality, and alcoholism are particularly common The investigations of the Eugenics Record Office led them to the study of this locality, and it was found by Miss Danielson a "field worker" of this institution, that practically all its less desirable inhabitants could be traced back to one of two original sources—namely, "a shiftless basket maker," possibly of French origin, and an Englishman, both of whom migrated into this district about the year 1800 Their descendants, referred to collectively as the Hill Folk, are described individually with considerable detail in Memoir No 1 Between 1879 and 1889 they absorbed almost one tenth of the whole amount spent by their town in Poor law relief, but in the last decade the proportion had risen to more than a quarter In the past 30 years 16 of them were sentenced for serious offences, mostly of a sexual character, and their punishments imposed a burden on the State of about $10 000 A glance at the extensive pedigree charts shows that feeblemindedness abounds in many of the lines and Professor Davenport has written a special chapter on its inheritance as illustrated among these people In this chapter he puts forward tentatively a theory which differs considerably from that suggested in the memoir previously published by himself and Mr Weeks on the inheritance of epilepsy According to the earlier view, normal development depends on the presence of a gametic factor transmitted in a Mendelian way Its total absence is shown by the development either of epilepsy or feeblemindedness Among the logical consequences of this theory it followed that two feebleminded with an unrelated healthy individual has always resulted in the offspring being all apparently healthy An elaborate genealogical table is given in the second volume, showing the probable descent of the abnormality from one of the parents of the original forefather of the stock, in which it appears that half the children of the forefather carried the concealed abnormality and half were completely free from it, as would be theoretically expected

Dementia præcox also showed itself with abnormal frequency in the "great family," there being 68 cases, and besides these there were 15 peculiar members who were not improbably slight examples of dementia præcox The author supports with considerable probability of correctness the view of Rudin, of Munich that this form of insanity is a Mendelian recessive In the same way he regards paralysis agitans, of which seven certain and two uncertain cases appeared in the family, as a Mendelian recessive , but naturally with a disease which appears so late in life the evidence in favour of this is much weaker than in the conditions previously mentioned

tinoscopy By JAMES THORINGTON A M, M D, Professor of Diseases of the Eye in the Philadelphia Polyclinic Sixth edition With 61 illustrations 10 coloured London Rebman, Limited 1912 Pp 71 Price 4*s* 6*d* net

ENGLAND was the birthplace of retinoscopy, and Bowman father France and Cuignet nursed it into vitality, but gland and the Moorfields Hospital proved that it was the thod *par excellence* of determining errors of refraction of e eye It remained for the medical profession of the ited States to confirm and extend the knowledge which ey would agree they learnt first at Moorfields and among o many American ophthalmic surgeons who have devoted ich labour and investigation to the theory and practice of inoscopy the name of Thorington holds an honoured place Thorington has brought his book up to date by the dition of new illustrations as well as of illustrations of w apparatus Apart from minor details of revision the ok retains its familiar characteristics It is clearly written d eminently practical As an introduction to retinoscopy know of no better guide but those who seek for knowdge of the somewhat complex theory of the subject must ek elsewhere

---

Text book of General Bacteriology By EDWIN O JORDAN, Ph D, Professor of Bacteriology in the University of Chicago and in Rush Medical College Third edition thoroughly revised Fully illustrated London and Philadelphia W B Saunders Company 1912 Pp 623 Price 13*s* net

THIS is the third edition of a work originally published 1908 It would seem, therefore, that it is much appreated The chief characteristic of the work claimed for it the author is that it treats the subject as part of a general eral scientific education and not merely as part of the chnical education of the medical man As a consequence e ground covered is rather more extensive than that ually dealt with in medical manuals though neither in is respect nor in the method of treatment is the difference eat

As the earlier editions have been fully reviewed in these lumns it is necessary to refer only to the chief changes in e present edition The work is lengthened by some 30 ges, and there are alterations in a few of the illustrations here is little rewriting but additional sections in some of e chapters give the results of recent work It has been cessary to alter considerably the chapter on leprosy he experiments of Clegg and Duval on the cultivation of e bacillus are given, but the subject is hardly brought up date, as there seems to be no mention of the varying rms and staining reactions of the organism or of the work Rost Bannerman Deycke or Kedrowski In relation cholera and typhoid fever the important question of arriers is discussed Rapid methods of cholera diagnosis s developed for quarantine work are given and the uestion of the recognition of allied spirilla is discussed he chapter on typhoid fever has also received additions n the appendix on diseases of unknown causation recent ork has been incorporated, especially Bernhardt's work on scarlet fever, which seems to indicate that the microorganism concerned is a filter passer, and the researches of Hektoen and Anderson and Goldberger on measles It is stated that typhus fever and Rocky Mountain spotted fever, though similar have now been shown to be distinct The recent important work on anterior poliomyelitis is also briefly sketched There are additions also in the section on plant diseases

The appearance of the work and the printing, as in the previous editions, are good, and the illustrations are well reproduced

Pye's Surgical Handicraft A Manual of Surgical Manipulations Minor Surgery and other Matters connected with the Work of House Surgeons and Surgical Dressers. Edited and largely rewritten by W H CLAYTON GREENE, B A M B, B C Cantab, F R C S Eng, Surgeon to St. Mary's Hospital Sixth edition Bristol John Wright and Sons Limited, London Simpkin, Marshall, Hamilton Kent and Co, Limited 1912 Pp 595 Price 12*s* 6*d* net

FOR more than a generation "Pye's Surgical Handicraft" has enjoyed a well deserved popularity amongst practitioners for the valuable aid it renders towards solving many of the difficult problems of minor surgery, and it is especially useful to house surgeons and dressers in their daily work But books tend to grow old and Mr Clayton Greene by the thorough revision to which he has subjected this work, has succeeded in giving it a new lease of life He has enlisted the aid of others in special branches of the subject and the result is all that could be desired Every dresser and house surgeon will find in the pages of this volume information which will materially assist him in his work

---

Lehrbuch der Augenheilkunde Edited by Dr THEODOR AXENFELD Professor of Ophthalmology in Freiburg i Br Third edition Jena Gustav Fischer 1912. Pp 761 Price 15 marks

A NEW edition of Axenfeld's text book of ophthalmology has been called for each succeeding two years The last edition is a considerable improvement upon its predecessors The difficulty of obtaining uniformity of treatment and a good balance in a work written by many authors was conspicuous in the first edition but has now been largely overcome The illustrations have been greatly improved and the coloured plates now form in themselves a very valuable ophthalmoscopic atlas The most recent advances in operative treatment such as trephining for glaucoma are briefly described and illustrated We commend the book warmly to students who are sufficiently acquainted with the German language

---

The History of the Prison Psychoses (Nervous and Mental [illegible] No 13) By Dr PAUL NITSCHE [illegible] ised translation by BERNARD GLUECK, M D With an Introduction by WILLIAM A WHITE, M D New York Journal of Nervous and Mental Disease Publishing Company 1912 Pp 84 Price $1 25

THIS critical and historical review of the subject of the prison psychoses deals exclusively with the German literature on the question and within these limits is admirably thorough and careful

Starting with the pioneer work of the elder Delbruck, who in 1853 published his observations on the cases of insanity occurring amongst the inmates of the penal institution of Halle the authors discuss the varying opinions which have been held by the different psychiatric schools down to the present time regarding the conception of a specific prison psychosis They divide their review into three parts In the first they consider the works affinities, thus, uranium produces changes in the distal part of the convoluted tubule, mercuric chloride does the same, but the transitional part is also affected, while cantharides and chromium affect the proximal part next the glomerulus The author gives a careful analysis of his results and draws a sharp distinction between the ' laying up ' of carmine granules in the convoluted tubules and the excretion of carmine in the urine The results are great interest, more especially to pathologists and nicians

The History of the Prison Psychoses (Nervous and Mental [illegible] No 13) By Dr PAUL NITSCHE [illegible] ised translation by BERNARD GLUECK, M D With an Introduction by WILLIAM A WHITE, M D New York Journal of Nervous and Mental Disease Publishing Company 1912 Pp 84 Price $1 25

THIS critical and historical review of the subject of the prison psychoses deals exclusively with the German literature on the question and within these limits is admirably thorough and careful

Starting with the pioneer work of the elder Delbruck, who in 1853 published his observations on the cases of insanity occurring amongst the inmates of the penal institution of Halle the authors discuss the varying opinions which have been held by the different psychiatric schools down to the present time regarding the conception of a specific prison psychosis They divide their review into three parts In the first they consider the works

Staining, by Andrew Balfour, contains the description of a new species of Sarcocystis, S. gazellæ, in which the author was able to distinguish two kinds of spores by means of vital staining with toluidin blue.—Ankylostomiasis in Grenada, by R. P. Cockin, not only comprises an account of the prevalence of this disease in Grenada, but also contains useful suggestions as to the measures to be taken to free the colony from it. The author has tested the effects of thymol, betanaphthol, eucalyptus oil, castor oil and chloroform respectively, on the removal of the parasites. The only satisfactory compound was found to be betanaphthol, as it quickly expelled the parasites, and moreover was cheap, and its administration was not followed by serious after-effects. With regard to thymol, the author remarks that when given in full doses of 30 grains it is dangerous and if in smaller doses is not effective, for when given to a fully-developed man in 20-grain doses it occasionally took as long as a month to rid him of the parasites. Accordingly, the action of the Porto Rico Commissioners in the free distribution of thymol is strongly condemned and considered to be very dangerous, as many of the natives suffer from dilatation of the heart, and, moreover, are extremely careless in attending to instructions regarding the taking of drugs.—Observations on the Biology of Ixodidæ, by G. H. F. Nuttall, contains descriptions of the biology and life-cycles of the following species of ticks: Ixodes putus, I. canisuga, I. hexagonus, I. ricinus, Hæmaphysalis leachi, H. punctata, *Hyalomma aegyptium, and Rhipicephalus appendiculatus.* Most of these species are concerned in the transmission of various animal diseases, and therefore this account of their biology is of the greatest value, as hitherto precise information of the life-histories of these ticks has been wanting. In every case they have been reared in the laboratory, and the author gives full directions of the methods employed for raising these parasites. A record of the biology of any tick should contain the following data: The time the tick remains upon the host; the behaviour of the sexes either on or off the host, together with notes on copulation; the time required for the metamorphoses from stage to stage; oviposition; longevity of the various stages; and the part played in pathology. In every case Professor Nuttall has endeavoured to supply these particulars.

The Medical Who's Who, 1913. Published annually. *London: The London and Counties Press Association,* Limited. Pp. 594. Price 10*s.* 6*d.* net.—Some prejudice was not unnaturally aroused against the lines on which it was originally proposed to publish this book as a selected list of medical men, but the publishers must be given credit for having endeavoured to remove all just ground for professional objection. It contains the names of all qualified practitioners who make the necessary returns on the form sent to them, and no condition attaches to the inclusion of the name. The book is primarily a personal, not a professional, record, though in the nature of things professional details necessarily come a great deal to the fore. It differs from the medical directories in giving information as to date and place of birth, parentage, early education, and other matters not directly connected with the practice of medicine or with medical science.

Clinique et Thérapeutique Obstétricale du Praticien. By P. RUDAUX, with the collaboration of A. GROSSE and V. LE LORIER. Paris: Vigot Frères. 1913. Pp. 890. Price Fr. 8.—The object of this work is to place in the hands of the practitioner when he is in difficulties information which will permit him to make an exact diagnosis and to apply rational treatment. The book contains nothing relating to the history of any disease, nor is there any discussion of pathological theories or descriptions of the pathological anatomy of the conditions considered. The authors have aimed at treating in considerable detail the various points concerned in diagnosis, and more particularly at laying stress on those which are of practical importance. It is, however, more especially treatment to which they have given the most space, and they have endeavoured to describe only those methods which not merely give the best results but which are the easiest to employ. The book is arranged in an alphabetical manner because the authors intend it to be a sort of dictionary of obstetric medicine in which information upon any particular subject can be found at once without reference to an index. In this book the student will find a great deal of valuable and practical information upon all the conditions which may affect the woman during pregnancy, parturition, and the puerperium, and also the various affections of the new-born child. The treatment recommended appears to us to be based upon sound lines and to exhibit a wise conservatism fitted to render it of value to the general practitioner, who no doubt will find the book the practical and helpful guide the authors intend it to be.

JOURNALS.

IN the *British Journal of Inebriety* for April Dr. H. Crichton Miller enters a vigorous plea for the recognition of the psychological factors in the treatment of alcoholism. He maintains that psychotherapy in one or other of its forms, as persuasion, suggestion, psycho-analysis, or even as restraint (which acts essentially through its mental influence), is competent to cure a very large proportion of inebriates, if due care be exercised to adapt the mode of treatment to the peculiarities of the individual case and if the psychic treatment is supplemented by remedies addressed to other special factors in the etiology, such, for instance, as circulatory disorders or epilepsy. Dr. Miller suggests that a very great financial saving might be effected and much more lasting results might be obtained by using the opportunities of enforced detention in prisons or reformatories for the vigorous and scientific treatment of the chronic drinkers on psychic lines. He also advocates as a cheap and effectual reform the establishment of anti-alcoholic dispensaries for the application of this and other therapeutic measures. An article on Children and Liquor Bars, by Mr. John Newton, deals with some of the undesirable results which have followed from the provisions of the Children Act of 1908 excluding children under 14 years of age from the bars of licensed premises. The writer of the article admits that the very general practice which has come into vogue of leaving the children at the door while the parents are drinking inside is a grave evil, but he believes that it should be possible to find a remedy by further legislation of a coercive character. It is regrettable to observe the inability of sane temperance reformers to realise the fact that, as public opinion is not going to enforce total abstinence, the rational course to pursue should be to reform the public-house so that it need not be a worse place for children than the gutter. A short paper by Professor G. Sims Woodhead on Alcohol and the Undergraduate also appears in this number.

DEATHS OF CENTENARIANS.—The death occurred recently at Hove of Mr. Frederick Halsey Janson, who on Feb. 8th reached his hundredth birthday. Mr. Janson was the oldest solicitor in the United Kingdom, having been admitted in 1835.—The death is announced from St. Petersburg of Mdlle. N. M. Bashmakoff, the *doyenne* of the Russian Red Cross Sisterhood, at the age of 103, who worked in the Crimean war of 1854-6 under the eminent Russian surgeon Pirogoff.

Staining, by Andrew Balfour, contains the description of a new species of Sarcocystis, S. gazellæ, in which the author was able to distinguish two kinds of spores by means of vital staining with toluidin blue.—Ankylostomiasis in Grenada, by R. P. Cockin, not only comprises an account of the prevalence of this disease in Grenada, but also contains useful suggestions as to the measures to be taken to free the colony from it. The author has tested the effects of thymol, betanaphthol, eucalyptus oil, castor oil and chloroform respectively, on the removal of the parasites. The only satisfactory compound was found to be betanaphthol, as it quickly expelled the parasites, and moreover was cheap, and its administration was not followed by serious after-effects. With regard to thymol, the author remarks that when given in full doses of 30 grains it is dangerous and if in smaller doses is not effective, for when given to a fully-developed man in 20-grain doses it occasionally took as long as a month to rid him of the parasites. Accordingly, the action of the Porto Rico Commissioners in the free distribution of thymol is strongly condemned and considered to be very dangerous, as many of the natives suffer from dilatation of the heart, and, moreover, are extremely careless in attending to instructions regarding the taking of drugs.—Observations on the Biology of Ixodidæ, by G. H. F. Nuttall, contains descriptions of the biology and life-cycles of the following species of ticks: Ixodes putus, I. canisuga, I. hexagonus, I. ricinus, Hæmaphysalis leachi, H. punctata, *Hyalomma aegyptium, and Rhipicephalus appendiculatus.* Most of these species are concerned in the transmission of various animal diseases, and therefore this account of their biology is of the greatest value, as hitherto precise information of the life-histories of these ticks has been wanting. In every case they have been reared in the laboratory, and the author gives full directions of the methods employed for raising these parasites. A record of the biology of any tick should contain the following data: The time the tick remains upon the host; the behaviour of the sexes either on or off the host, together with notes on copulation; the time required for the metamorphoses from stage to stage; oviposition; longevity of the various stages; and the part played in pathology. In every case Professor Nuttall has endeavoured to supply these particulars.

The Medical Who's Who, 1913. Published annually. *London: The London and Counties Press Association,* Limited. Pp. 594. Price 10*s.* 6*d.* net.—Some prejudice was not unnaturally aroused against the lines on which it was originally proposed to publish this book as a selected list of medical men, but the publishers must be given credit for having endeavoured to remove all just ground for professional objection. It contains the names of all qualified practitioners who make the necessary returns on the form sent to them, and no condition attaches to the inclusion of the name. The book is primarily a personal, not a professional, record, though in the nature of things professional details necessarily come a great deal to the fore. It differs from the medical directories in giving information as to date and place of birth, parentage, early education, and other matters not directly connected with the practice of medicine or with medical science.

Clinique et Thérapeutique Obstétricale du Praticien. By P. RUDAUX, with the collaboration of A. GROSSE and V. LE LORIER. Paris: Vigot Frères. 1913. Pp. 890. Price Fr. 8.—The object of this work is to place in the hands of the practitioner when he is in difficulties information which will permit him to make an exact diagnosis and to apply rational treatment. The book contains nothing relating to the history of any disease, nor is there any discussion of pathological theories or descriptions of the pathological anatomy of the conditions considered. The authors have aimed at treating in considerable detail the various points concerned in diagnosis, and more particularly at laying stress on those which are of practical importance. It is, however, more especially treatment to which they have given the most space, and they have endeavoured to describe only those methods which not merely give the best results but which are the easiest to employ. The book is arranged in an alphabetical manner because the authors intend it to be a sort of dictionary of obstetric medicine in which information upon any particular subject can be found at once without reference to an index. In this book the student will find a great deal of valuable and practical information upon all the conditions which may affect the woman during pregnancy, parturition, and the puerperium, and also the various affections of the new-born child. The treatment recommended appears to us to be based upon sound lines and to exhibit a wise conservatism fitted to render it of value to the general practitioner, who no doubt will find the book the practical and helpful guide the authors intend it to be.

DEATHS OF CENTENARIANS.—The death occurred recently at Hove of Mr. Frederick Halsey Janson, who on Feb. 8th reached his hundredth birthday. Mr. Janson was the oldest solicitor in the United Kingdom, having been admitted in 1835.—The death is announced from St. Petersburg of Mdlle. N. M. Bashmakoff, the *doyenne* of the Russian Red Cross Sisterhood, at the age of 103, who worked in the Crimean war of 1854–6 under the eminent Russian surgeon Pirogoff.

the maximum temperature was sometimes as high as 60° early in the month, it was as low as 37° just before the middle, but by the 25th it was up to 70°, and on the last four days rose to 81° or 82°. Sharp frost was experienced about the middle of the month, the lowest temperature recorded being 25°. Considered generally, however, the weather was warmer than in any part of this country, as well as drier. Only six or seven days were rainy, and the aggregate fall no more than 0.7 in. Similar changes of temperature were general in the east and north-east of France. At Paris, where the early part of the month was mild and the middle rather cold, the end was only a little less hot than at Berlin, and as a whole the French capital was warmer, having a mean maximum temperature of 59° and a mean minimum of 42°, both values being a degree higher than those at Berlin. Paris was, however, more rainy than Berlin; more or less rain was experienced on nearly half the days, and the total fall amounted to 2.23 in. As in this country, the month was relatively dull, the total sunshine being no more than 151 hours. On the Riviera there was a marked increase of warmth. At Nice, where the mean maximum temperature was 60°, and the mean minimum 45°, the shaded thermometer rose to 70° or above on three afternoons, but the weather was never so hot as during the latter days of the month at Paris. Rain occurred on nine days, and yielded a total of 3.7 in., but generally the weather was very fine. Much more rain fell at Biarritz, and the weather generally, although nearly as warm as at Nice, was far less fine. Several days were rainy throughout, and the aggregate for the month was as much as eight inches, more than three times the total at Kew. In Italy also the month was more or less wet, especially over the northern half. During the first fortnight, and occasionally later, rain fell in large quantities, that at Rome almost equalling the heavy total at Biarritz. The first fortnight was, too, very cool for the time of year, the temperature barely exceeding that in London. Subsequently, however, there was a very appreciable increase of warmth. At Madeira the temperature was little affected by the northward march of the sun, and the mean maximum was about the same (64°) as during the preceding month, while the mean minimum (49°) showed but slight variation. As a rule the weather was dry and bright, but during the first fortnight rain occurred on eight days.

MANUAL TRAINING

THE new education, of which so much is heard nowadays, is in reality the old education—i.e., the ideal of Socrates. That is to say, it is drawing out knowledge, and not cramming the pupil with facts as a chicken is crammed with food. And in modern education manual training is gradually becoming more and more common, though not yet as common as it should be. The Penal Reform League has just reprinted a paper upon this subject by Mr. T. C. Horsfall, who is well known as an expert upon education. The paper was originally written for a periodical called *Manual Training*, but the committee of the Penal Reform League thought it good to reprint it because, to use its own words, "there are here indicated some of the measures by which the education of our youth may be made more preventive of crime, that is more effective in fitting them to live worthy lives." Mr. Horsfall starts by laying down the precept that a child should feel love and respect for its teachers, and with this we quite agree. But there is reason for the warning which the Penal Reform League gives that this affection may be abused. Mr. Horsfall maintains that for a teacher to bring out this affection he must have the opportunity of giving his pupils both what they need and what they desire, and the two things for which he pleads are organised games and handicraft. Organised games, such as cricket and football, are of the greatest value, for they teach what is perhaps the crying need of the day—namely, discipline. Manual training, too, excites children's interests in a way which book learning alone never will, for by its means they can apply what they are taught. Even Mr. Squeers, with all his deficiencies as a teacher, had in a way grasped this fact, as our readers will see if they recall to mind the manner in which he connected the spelling of "window" and the cleaning of the same. Mr. Horsfall gives a short account of the results of manual instruction as given in Germany and in our own country at Sompting, and pleads for a general adoption of the new system. He quotes the late Godfrey Leland as saying that he had never known a man who could use his hands skilfully to go quite to the dogs. Opinions may differ as to when "quite to the dogs" begins, but certainly many skilled handicraftsmen have led anything but reputable lives. To mention only two, Benvenuto Cellini could certainly use his hands, but his way of life was far from admirable; while to come down to modern times, Charles Peace was a skilled violinist, could make a violin, was a first-class burglar, and ended his career on the scaffold. For all that, we quite agree that manual training is an asset of great value in the education of youth.

THE SPECTRUM OF THE ALKALOID AS AN AID TO ITS DETECTION AND ESTIMATION

IN a recent lecture delivered before the Royal Institution Dr. J. J. Dobbie, F.R.S., the principal chemist of the Government laboratories, drew attention to the value of the study of the absorption spectrum of the alkaloids which had not only thrown light upon the structure of these bodies, but had led also to a method for their detection and estimation. The absorption occurs in the ultra-violet end of the spectrum, and means are devised by which a favourable production of this can be obtained. To begin with, the source of light used is obtained by sparking one of the metals such as iron or a combination of metals which give rays rich in ultra-violet. Next, the prisms and lenses of the apparatus are made of quartz, which, unlike glass, is readily permeable by the ultra-violet rays. The lines of selective absorption of the alkaloid dissolved in a diactinic solvent are photographed. It is found that the alkaloids generally have very characteristic spectra by means of which they can be distinguished with certainty from one another, except when they are homologous or otherwise very closely related structurally. The method may therefore be used with considerable advantage in examinations for the presence of alkaloids to confirm the results obtained by the usual chemical tests. Although the chemical tests are as a rule sufficiently distinct, the gravity of the circumstances in which they have frequently to be applied renders it desirable to obtain all the confirmatory evidence possible. Dr. Dobbie says that the minutest quantities of alkaloids can be detected by this means, the method rivalling the colour reactions for the alkaloids in regard to delicacy. Thus, with a quantity of strychnine not exceeding 1/500 of a grain, a clearly defined spectrum of the alkaloid can be obtained. Similarly, the lines are perfectly distinct and peculiar when 1/200 of a grain of morphine and 1/100 of a grain of nicotine respectively are examined in the diactinic cell. As is pointed out, the use of the spectroscope in the detection and estimation of alkaloids in cases of poisoning possesses certain advantages of the highest importance. One is that the material is not the maximum temperature was sometimes as high as 60° early in the month, it was as low as 37° just before the middle, but by the 25th it was up to 70°, and on the last four days rose to 81° or 82°. GANGRENE OF ALL FOUR EXTREMITIES.

IN an article published in THE LANCET of Nov. 30th, 1912, on "Beleaguered Constantinople," which detailed some of Mr. Samuel Osborn's experiences with the British Red Cross contingent at Constantinople, reference was made to an interesting case of symmetrical gangrene of both hands and both feet in a Turkish soldier, under the care of Mr. John F. McClean, at the British Seamen's Hospital. We have now received through Mr. Osborn a photograph of this patient taken on leaving hospital. Mr. McClean suggests that the gangrene was most probably due to the action of some high explosive, such as melinite. After the operation Mr. McClean and his assistants spent much time and trouble in educating the patient to do everything for himself, and in the end he repaid them for their care, for he left them, to use Mr. McClean's own words, "walking out of the gate on his stumps, able to feed himself, and attend to his bodily functions all on his own." That this is not an exaggeration can well be understood from inspection of the snapshot which we reproduce.

INTESTINAL PERFORATION IN PARATYPHOID FEVER.

THE bacteriological investigation of cases of typhoid fever led, as is well known, to the discovery that in a certain number the causal organism is not the typhoid bacillus but a microbe of the same group which has been termed the "paratyphoid bacillus." The illness produced by this bacillus—paratyphoid fever—is clinically indistinguishable from typhoid fever, and usually resembles a benign form of the latter. Out of 162 recorded cases only 6 have been fatal. Intestinal lesions like those of typhoid fever are rare, and it has been asserted that perforation never occurs. In the *Progrès Médical* of March 1st M. Grenier, an army surgeon, has reported a case which shows that this generalisation is premature. A soldier in the foreign legion, aged 28 years, had good health but was slightly addicted to alcohol. He had never had typhoid fever. On July 25th, 1912, he was taken ill with foul tongue, a little diarrhœa, headache, and slight fever. On August 5th he was examined by M. Grenier. Forty hours previously he was seized with acute pain in the right iliac fossa. Examination showed a dry tongue, rose spots on the abdomen, abdominal rigidity with pain which was acute on pressure, especially on the right side. There was bilious vomiting, the face was pinched, the pulse was 120, and the temperature 103·3° F. The diagnosis of peritonitis consecutive to typhoid perforation was obvious. In spite of the interval which had elapsed laparotomy was performed. Sero-purulent fluid escaped from the general peritoneal cavity and pus from the pelvic cavity. On a coil of ileum near the cæcum a lenticular perforation was found over an inflamed Peyer's patch. There were no adhesions. The perforation was sutured, and three large drainage-tubes were placed in the pelvis. The abdominal wound was closed, and saline solution was administered hypodermically and by the rectum according to Murphy's method. Death took place on the following day. At the necropsy the intestinal coils were found adherent to one another. The lower part of the ileum was swollen and showed numerous inflamed and hæmorrhagic Peyer's patches. The mesenteric glands were enlarged. The spleen was large and diffluent. A blood culture made during life showed an extremely motile organism with all the characters of paratyphoid bacillus of the B type.

THE DRUIDIC SERPENT'S EGG.

THE sea-urchin, from birth to maturity, was one of the subjects recently demonstrated before the Section of Medicine of the Royal Society of Medicine by Dr. Gustave Monod, of Vichy. The films moved at about 112 times the speed at which nature moves, and thus we were afforded the strange sight of the process of cell-fissure taking place with something like the rapidity of an ordinary human action. It was, to quote the lecturer's phrase, as though we witnessed the very inception of life. The sea-urchin for long maintained a central position in the materia medica of the Gallic world. For in its fossil state it was the serpent's egg of the druidical pharmacopœia, a potent talisman and cure all, which the subtle Druids picked up with care on the northern shores of France and sold, often for its weight in gold, to their credulous Roman conquerors. It was believed that a genuine snake's egg or "anguinum," even when encased in gold, would float against the current of a stream. The elder Pliny describes one which he had examined. "It is about the size of a moderately large round apple, and has a cartilaginous rind studded with cavities like those on the arms of a polypus." Here perhaps we have a reference to the shell of the sea-urchin rather than to its fossil. Gigantic sea-urchin shells are of course familiar to the Celts in Iona and elsewhere. The serpent's egg, or *ovum anguinum*, is described by Nehemiah Grew in his "Catalogue and Description of the Natural and Artificial Rarities belonging to the Royal Society" (1681). It is so called, he avers, from its "roundness, and form of snakes tailes pointing upward, and towards the middle of the stone." He believes it to be an "*Echinites*," though Agricola makes it a sort of Brontias. All sorts of fossils figure in the ancient materia medica. Thus the "Judaic Stones" resembled almonds, acorns, olive-stones, and so forth. They were found in the clefts of rocks in Judæa, and "are dissolved with spirit of nitre, not without effervescence, especially when reduced to powder. And may therefore be justly esteemed diuretick, and so sometimes bring away or (as people think) break the stone; for which, by Pliny, 'tis call'd Tecolithos." These fossils were usually selected by searchers on signaturist principles and because they were pretty or singular. The ancient Celts gave a curious account of the origin of the serpent's egg. It was believed to be produced "from the saliva and frothy sweat of a number of serpents writhing in an entangled mass, and to be tossed up into the air as soon

THE DRUIDIC SERPENT'S EGG.

THE sea-urchin, from birth to maturity, was one of the subjects recently demonstrated before the Section of Medicine of the Royal Society of Medicine by Dr. Gustave Monod, of Vichy. The films moved at about 112 times the speed at which nature moves, and thus we were afforded the strange sight of the process of cell-fissure taking place with something like the rapidity of an ordinary human action. It was, to quote the lecturer's phrase, as though we witnessed the very inception of life. The sea-urchin for long maintained a central position in the materia medica of the Gallic world. For in its fossil state it was the serpent's egg of the druidical pharmacopœia, a potent talisman and cure all, which the subtle Druids picked up with care on the northern shores of France and sold, often for its weight in gold, to their credulous Roman conquerors. It was believed that a genuine snake's egg or "anguineum," even when encased in gold, would float against the current of a stream. The elder Pliny describes one which he had examined. "It is about the size of a moderately large round apple, and has a cartilaginous rind studded with cavities like those on the arms of a polypus." Here perhaps we have a reference to the shell of the sea-urchin rather than to its fossil. Gigantic sea-urchin shells are of course familiar to the Celts in Iona and elsewhere. The serpent's egg, or *ovum anguinum*, is described by Nehemiah Grew in his "Catalogue and Description of the Natural and Artificial Rarities belonging to the Royal Society" (1681). It is so called, he avers, from its "roundness, and form of snakes tailes pointing upward, and towards the middle of the stone." He believes it to be an "*Echinites*," though Agricola makes it a sort of Brontias. All sorts of fossils figure in the ancient materia medica. Thus the "Judaic Stones" resembled almonds, acorns, olive-stones, and so forth. They were found in the clefts of rocks in Judæa, and "are dissolved with spirit of nitre, not without effervescence, especially when reduced to powder. And may therefore be justly esteemed diuretick, and so sometimes bring away or (as people think) break the stone; for which, by Pliny, 'tis call'd Tecolithos." These fossils were usually selected by searchers on signaturist principles and because they were pretty or singular. The ancient Celts gave a curious account of the origin of the serpent's egg. It was believed to be produced "from the saliva and frothy sweat of a number of serpents writhing in an entangled mass, and to be tossed up into the air as soon in such circumstances is to ascertain whether there has been foul play, and it is not a measure to be undertaken lightly. Where a medical practitioner has attended the deceased it implies that if there has been poisoning or any other wrongful act or omission conducing to the death he has overlooked it, and it further suggests that someone may have caused the death by a felonious act. So far as the medical attendant is concerned it is an act of discourtesy to him to ignore him in granting the exhumation, and, more than this, an exhumation such as that referred to inflicts pain upon relatives and causes the circulation of rumours of a very painful character. Reference need hardly be made to the names of the two medical attendants of the late Colonel Meeking in order to point out that in his case the possibility of error was an extremely remote one. In general, however, it may be said that it should be possible for the Home Office, by inquiry addressed to the medical attendant by a person qualified to make it, to satisfy itself as to the possibility or likelihood of a mistake having been made, or if there is any other reason for regarding the medical certificate of the cause of death with suspicion. If after such an inquiry there remained an element of doubt or any probability or even possibility that the suspicions of those asking for post mortem examination of the remains had any substantial basis, no question of the feelings of the medical attendant or of surviving relatives should, of course, intervene to prevent full investigation. The interests of public justice on such occasions must necessarily override other considerations. And Dr. Cautley, in the protest to which we have referred, does not demand otherwise.

THE ETIOLOGY AND TREATMENT OF RHEUMATOID ARTHRITIS.

THE causation of rheumatoid arthritis has been the subject of much speculation and research. Its frequent association with chronic infections and its analogies with other acute and chronic processes in joints of proved infective origin have given considerable support to the view that at any rate some of the conditions comprised under the somewhat comprehensive term of rheumatoid arthritis are also due to chronic microbic infections. We publish in this week's issue of THE LANCET two interesting and suggestive contributions upon this subject. The first of these, by Dr. H. Warren Crowe, of Yelverton, is more particularly concerned with the etiology of the disease. The second by Dr. A. Bertram Soltau, of Plymouth, deals especially with the results of treatment by certain vaccines, and the general results obtained by the two observers are substantially in agreement. Dr. Crowe states that it has been his practice for some years to examine the urine bacteriologically in cases of arthritis, neuritis, and muscular rheumatism, and he has found that when a local bacterial nidus exists the same organism can usually be recovered from the urine. He has found a group of organisms in the urine which he has distinguished as staphyloidcocci, and he has subdivided these into six distinctly different organisms, to one of which he has applied the name of staphyloidcoccus A. He has found the organism to occur with remarkable frequency in the urine of patients suffering from rheumatoid arthritis. He believes it to be the commonest so called staphylococcus found in urine, and states that it closely resembles that group of germs to which the generic name of micrococcus epidermidis albus is applied. Dr. Soltau has used a vaccine made from this staphyloidcoccus A of Dr. Crowe in a considerable number of cases, and describes his results which he regards as encouraging. He has found that some of his cases showed the presence of staphyloidcoccus A alone, while in others the infection was mixed, such organisms as streptococci and bacillus coli communis being present with the staphyloidcoccus A. In the latter group of cases he has generally given a vaccine from the secondary organisms first, and later given the staphyloidcoccus A vaccine. In regard to the dosage of the latter, it is necessary to start with very small doses, such as half a million, since marked reactions occur even with these small doses. Both observers are careful to avoid making exaggerated claims as to the significance of their observations. They do not maintain that the sole pathogenic cause of rheumatoid arthritis is the organism which they have worked with, but point out that its frequent presence in the urine and the good results of its careful use as a vaccine are suggestive, and should encourage further interest in the subject. This disease in some of its forms is so crippling and is productive of so much pain and disability, that we must welcome any new work which offers a hope of real curative rather than palliative treatment, and we shall await further experience on this method of treatment with interest.

THE DANGERS OF THE OPERATION FOR ADENOIDS.

THERE is an impression among the laity, and even in the profession that the operation for adenoids is devoid of danger. This is no doubt due to the few cases of complications following this extremely common operation which have been described. For this there are three reasons. First, few surgeons enjoy publishing their accidents. Second, the patient is often not under the observation of the surgeon after the operation. Third, the operation is frequently performed by the general practitioner, who is too busy to publish his cases. In the *Johns Hopkins Hospital Bulletin* for April Dr. W. E. Grove has reported two cases of complications following the operation for adenoids and reviewed the literature of the subject, which is almost entirely German. The most frequent and dangerous of these complications may be divided into two groups—hæmorrhage and infections. Post operative hæmorrhage may be very severe. In 1907 Barrell and Orr reported seven fatal cases. Post-operative inflammation may be expected when it is remembered that many microbes are found on the surface of adenoids. Indeed, the fever which usually follows the operation is an indication of an infection which the organism usually overcomes. Six cases of septicæmia following the operation have been recorded. Coley observed one case of endocarditis and found two other cases in the literature. Practically all the acute infectious diseases of childhood have been observed as post operative sequelæ. The cases of scarlet fever and diphtheria may be explained in two ways. Either the operation was performed during the incubation period or the patients were carriers of the disease, the microbe being present in the throat. Acute local post operative infections are frequent. Trofinow saw five cases of angina follicularis after 508 operations. Gerber observed a peritonsillar abscess a short time after removal of adenoids in an adult. Grönbeck described four cases of extensive post operative adenitis. Nine cases of torticollis following the operation have been described. Erysipelas has also been observed. Pulmonary complications, such as pneumonia and abscess of the lung, have been described; they are evidently due to aspiration of blood or lymphoid tissue during the operation. Fatal meningitis has also been reported. Infection of the ear through the Eustachian tube are among the most frequent, if, indeed, they are not the most frequent, complications of the operation. Infections of the nasal sinuses appear to be much less frequent and have received little attention in literature. Henke described the case of a girl, aged 13 years, in whom severe infection of the frontal sinus with œdema of the eyelids and neighbouring parts developed in such circumstances is to ascertain whether there has been foul play, and it is not a measure to be undertaken lightly Where a medical practitioner has attended the deceased it *implies that if there has been poisoning or any other* wrongful act or omission conducing to the death he has overlooked it, and it further suggests that someone may have caused the death by a felonious act So far as the medical attendant is concerned it is an act of discourtesy to him to ignore him in granting the exhumation, and, more than this, an exhumation such as that referred to inflicts pain upon relatives and causes the circulation of rumours of a very painful character Reference need hardly be made to the names of the two medical attendants of the late Colonel Meeking in order to point out that in his case the possibility of error was an extremely remote one In general, however, it may be said that it should be possible for the Home Office, by inquiry addressed to the medical attendant by a person qualified to make it, to satisfy itself as to the possibility or likelihood of a mistake having been made, or if there is any other reason for regarding the medical certificate of the cause of death with suspicion If after such an inquiry there remained an element of doubt or any probability or even possibility that the suspicions of those asking for post mortem examination of the remains had any substantial basis, no question of the feelings of the medical attendant or of surviving relatives should, of course, intervene to prevent full investigation The interests of public justice on such occasions must necessarily override other considerations And Dr Cautley, in the protest to which we have referred, does not demand otherwise

THE ETIOLOGY AND TREATMENT OF RHEUMATOID ARTHRITIS

THE causation of rheumatoid arthritis has been the subject of much speculation and research Its frequent association with chronic *infections* and its analogies with other acute and chronic processes in joints of proved infective origin have given considerable support to the view that at any rate some of the conditions comprised under the somewhat comprehensive term of rheumatoid arthritis are also due to chronic microbic *infections* We publish in this week's issue of THE LANCET two interesting and suggestive contributions upon this subject The first of these, by Dr H Warren Crowe, of Yelverton, is more particularly concerned with the etiology of the disease The second by Dr A Bertram Soltau, of Plymouth, deals especially with the results of treatment by certain vaccines and the general results obtained by the two observers are substantially in agreement Dr Crowe states that it has been his practice for some years to examine the urine bacteriologically in cases of arthritis, neuritis, and muscular rheumatism, and he has found that when a local bacterial nidus exists the same organism can usually be recovered from the urine He has found a group of organisms in the urine which he has distinguished as staphyloidcocci, and he has subdivided these into six distinctly different organisms, to one of which he has applied the name of staphyloidcoccus A He has found the organism to occur with remarkable frequency in the urine of patients suffering from rheumatoid arthritis He believes *it to be the commonest* so called *staphylococcus* found in urine, and states that it closely resembles that group of germs to which the generic name of micrococcus epidermidis albus is applied Dr Soltau has used a vaccine made from this staphyloidcoccus A of Dr Crowe in a considerable number of cases, and describes his results which he regards as encouraging He has found that some of his cases showed the presence of staphyloidcoccus A alone, while in others the infection was mixed, such organism, as streptococci and bacillus coli communis being present with the staphyloidcoccus A In the latter group of cases he has generally given a vaccine from the secondary organisms first, and later given the staphyloidcoccus A vaccine In regard to the dosage of the latter, it is necessary to start with very small doses, such as half a million, since marked reactions occur even with these small doses Both observers are careful to avoid making exaggerated claims as to the significance of their observations They do not maintain that the sole pathogenic cause of rheumatoid arthritis is the organism which they have worked with, but point out that its frequent presence in the urine and the good results of its careful use as a vaccine are suggestive, and should encourage further interest in the subject This disease in some of its forms is so crippling and is productive of so much pain and disability, that we must welcome any new work which offers a hope of real curative rather than palliative treatment, and we shall await further experience on this method of treatment with interest

THE DANGERS OF THE OPERATION FOR ADENOIDS.

THERE is an impression among the laity, and even in the profession that the operation for adenoids is devoid of danger This is no doubt due to the few cases of complications following this extremely common operation which have been described For this there are three reasons First, few surgeons enjoy publishing their accidents Second, the patient is often not under the observation of the surgeon after the operation Third, the operation is frequently performed by the general practitioner, who is too busy to publish his cases In the *Johns Hopkins Hospital Bulletin* for April Dr W E Grove has reported two cases of complications following the operation for adenoids and reviewed the literature of the subject, which is almost entirely German The most frequent and dangerous of these complications may be divided into two groups—hæmorrhage and infections Post operative hæmorrhage may be very severe In 1907 Barrell and Orr reported seven fatal cases Post-operative inflammation may be expected when it is remembered that many microbes are found on the *surface of adenoids* Indeed, the *fever* which usually follows the operation is an indication of an infection which the organism usually overcomes Six cases of septicæmia following the operation have been recorded Coley observed one case of endocarditis and found two other cases in the literature Practically *all* the acute infectious diseases of childhood have been observed as post operative sequelæ The cases of scarlet fever and diphtheria may be explained in two ways Either the operation was performed during the incubation period or the patients were carriers of the disease, the microbe being present in the throat Acute local post operative infections are frequent Trofinow saw five cases of angina follicularis after 508 operations Gerber observed a peritonsillar abscess a short time after removal of adenoids in an adult Grönbeck described four cases of extensive post operative adenitis Nine cases of torticollis following the operation have been described Erysipelas has also been observed Pulmonary complications, such as pneumonia and abscess of the lung, have been described they are evidently due to aspiration of blood or lymphoid tissue during the operation Fatal meningitis has also been reported Infection of the ear through the Eustachian tube are among the most frequent, if, indeed, they are not the most frequent, complications of the operation *Infections of the nasal sinuses* appear to be much less frequent and have received little attention in literature Henke described the case of a girl, aged 13 years, in whom severe infection of the frontal sinus with œdema of the eyelids and neighbouring parts developed certain defects in the material or construction, to the police possibly manslaughter from the neglect of another to provide certain safeguards. Until the fundamental purpose of the inquiry is determined it is waste of time to consider what alterations should be made in the coroner's law; for it is clear that the qualifications in the coroner and the procedure adapted to one purpose are not those suited to another. Speaking broadly, we have to choose between either a legal or a scientific inquiry.

Apart from the actual statements of coroners, evidence of the diversity of principle and practice is furnished by the statistics relating to inquests. For instance, some coroners regard a case of Bright's disease or cirrhosis of the liver as "natural death," others enter it under "excessive drinking." The result is that one town will show an apparent mortality from the latter cause enormously greater than that in another town of the same size and character. Some coroners accept any evidence as sufficient to establish insanity in cases of suicide, others require evidence of its existence in the ordinary meaning of the word. In Manchester and Newcastle, for example, out of 84 suicides in 1910, there were 41 verdicts of *felo-de-se*, while in London out of 540 suicides there were only seven such verdicts. In one district in London post-mortem examinations were made in 96 per cent. of the inquests held, in another in only 29 per cent. Perhaps the most striking feature is the difference in the proportion of inquests held in town and country. The Registrar-General's returns show that out of 132,505 deaths in 24 large towns, inquests were held in 9·9 per cent., the percentage of violent deaths being 4·1. In 22 rural and scattered areas, out of 77,890 deaths the percentage of inquests was 5·5, the percentage of violent deaths only dropping to 3·9. Further analysis shows that the difference lies almost entirely in the number of natural deaths investigated, the percentage of such verdicts in inquests held being about 50 in towns and 25 in the country. In other words, the coroners in country districts tend to hold inquests only when there is some suspicion of violence. In towns they investigate a larger number of deaths in which there is no suspicion but the pathological cause is doubtful. One might have expected that inquests would have been fewer in towns, since the opportunities of making complete preliminary inquiries are much greater than in the country; but the reverse is the case.

It appears to me that there is only one adequate explanation of this difference—namely, that the factor of distance influences the coroner. In the country most of the coroners are part-time officers, [illegible] medical man in busy practice. The [illegible] not large, and to tra[illegible] trouble of summoning a jury and arranging for the attendance of witnesses may mean a serious interruption of work. Under such circumstances coroners are apt not to hold inquests except in cases of urgent necessity. If this explanation is correct I submit that it indicates a serious state of affairs. It means either that a large number of unnecessary inquests are being held in towns or that inquests are not held in the country where they should be, or both. In the first alternative persons are being needlessly put through a painful ordeal, jurymen and witnesses are called upon to waste their time, and the local authority is being caused unnecessary expense. If the second be the case, then many deaths in the country are not being properly investigated. In either case the position is extremely unsatisfactory and indicates the necessity of laying down some general principles for coroners to follow. As bearing upon the holding of unnecessary inquests in towns, let me quote the following from the evidence of Mr. Ollis, chief officer of the Public Control Department of the London County Council, before the Departmental Committee:—

> An officer of the Council was instructed to watch proceedings at inquests as a member of the public. He attended 23 different courts, [illegible] grouped, and the time spent upon an inquest did not indicate that any public good was being served by the inquest being held.

Sources of Information open to Coroners.

For the proper investigation of unnatural deaths it is obvious that the coroners should obtain early and complete information of all such cases, but it is more than doubtful whether the present system or systems provide this.

The police constitute the principal source from which [illegible] courts—is entirely separate from, and independent of, the coroner. In a [illegible] pected the inve[illegible] the police, and [illegible] arrests and charging persons before a magistrate. They are our real safeguard, and any change in the coroner's law would leave them unaffected.

The registrar of deaths exercises the function of reading certificates of death and forwarding such of them as he considers unsatisfactory to the coroner. I submit that the duty of revising medical certificates cannot be satisfactorily discharged by anyone other than a medical man, and the practice was condemned by the Committee on Death Certification as long ago as 1893. Evidence was given before the Coroners Committee that some of the registrars are ignorant of their duties and do not report cases they ought to do.

Interesting confirmation of this was given by Dr. H. T. Herring, medical referee to the London Cremation Society. When a body is to be cremated two medical certificates are required, and these are scrutinised by the medical referee. Between the years 1902 and 1909 11 deaths were referred by Dr. Herring to coroners, although the certificates were apparently quite in order and would have been sufficient for burial. The coroners considered it necessary to hold inquests in seven of these cases, and in some of them death was found not to have been due to natural causes. Dr. Herring estimated that there are in London alone at least 210 persons buried every year on the registrar's certificate [illegible]n held. [illegible] from the fact that the [illegible] th a medical certificate [illegible] burial upon receipt of [illegible] may be derived from any unqualified bonesetter or herbalist or even from persons who make no pretence to medical knowledge whatever. This is a very grave responsibility to place on a person without knowledge of medicine. Let me call your attention to the facts that, apart from 814 deaths the causes of which were unknown or ill-defined, there were, according to the Registrar-General's returns in 1910, in England and Wales, 199 deaths from accident or negligence which were certified by medical practitioners without any inquest being held, and 690 deaths which were neither certified by doctors nor reported to coroners. These facts show that even the existing law is not carried out, and are alone sufficient to condemn the system.

The coroner's officer.—This functionary, though unknown to statute, exercises duties of a most inquisitorial character, and it is largely upon his inquiries that a coroner decides whether or not to hold an inquest. Where he is a police constable or sergeant he is probably efficient, but many are private persons and may be quite incompetent. Coroners' officers are usually paid by fee, so that it is to their interest to have as many inquests held as possible. An additional objection is that their inquiries in cases of crime may, as Inspector Shorthouse pointed out, frustrate the police investigations.

Medical practitioners.—In consequence of the pain and publicity attaching to inquests the public are naturally very reluctant to face these inquiries, and in doubtful cases strong pressure is always brought to bear upon practitioners to avoid an inquest if possible. The result is that many cases in which the pathological cause of death is unknown are not reported if they appear to be free from suspicion. But it is impossible to say that any death is free from suspicion as long as the pathological cause is undetermined. With the simplified and semi-private procedure I shall suggest presently, more of these cases would be reported and crime might be detected.

Let me give some actual instances. The death of Mary Chapman, the first victim of the murderer Chapman or Klowsowski, was certified as due to phthisis, but when the body was exhumed no trace of disease was found in the lungs. If an investigation had been made in this case the lives of the two later victims would have been saved. About certain defects in the material or construction, to the police possibly manslaughter from the neglect of another to provide certain safeguards. Until the fundamental *purpose* of the inquiry is determined it is waste of time to consider what alterations should be made in the coroner's law; for it is clear that the qualifications in the coroner and the procedure adapted to one purpose are not those suited to another. Speaking broadly, we have to choose between either a legal or a scientific inquiry.

But it is impossible to say that any death is free from suspicion as long as the pathological cause is undetermined. With the simplified and semi-private procedure I shall suggest presently, more of these cases would be reported and crime might be detected.

Let me give some actual instances. The death of Mary Chapman, the first victim of the murderer Chapman or Klowsowski, was certified as due to phthisis, but when the body was exhumed no trace of disease was found in the lungs. If an investigation had been made in this case the lives of the two later victims would have been saved. About consisting of a lay coroner and a jury of working men is competent to determine the highly scientific questions involved, and Sir Frederic Hewitt in his evidence before the Coroner's Committee stated that the true facts are often not brought out *I have now records of some* hundreds of such inquests, and in all of them the jury found that the anæsthetic had been properly administered This seems to indicate either that the risk of negligent administration is so slight that the inquiry is superfluous or, more probably, that the tribunal is incapable of detecting faulty procedure *It is amusing to note the differences of view* among coroners as to the effect of these inquests upon the public The coroner for Manchester said 'The one thing I do deprecate is not the inquest, but publicity In my practice I endeavour as far as possible to keep these matters quiet, to keep them from the public for the sake of other patients" *The coroner for Birmingham stated* "One of the objects I think of holding an inquest is to maintain public confidence in the medical profession and medical institutions, and I think it does maintain that confidence for people to feel when a death occurs under such circumstances that it is inquired into and you can always put it to a jury'

Mr Pepper in his evidence before the Departmental Committee stated that he had seen coroners go wrong many times over the medical evidence, and scattered through the volumes of the report are numerous instances where coroners have failed to appreciate the medical points One coroner in a case of starvation attached great importance to the viewing of the body by the jury *He said* "The evidence given at the inquest to uneducated minds without having seen the body would have conveyed very little having seen the body of the old woman with the bones almost through her skin, the jury immediately formed their own opinion outside the oral evidence and found a verdict of manslaughter" He was asked if he thought proceedings would not have been taken if the jury had not seen the body, and replied "I am perfectly sure they would not as I heard it said, 'What an absurd thing to bring in a verdict of manslaughter' I have not the slightest doubt that that woman was convicted purely on the viewing of the body" It is clear that such a case ought to turn solely on the medical evidence Starvation can only be proved by excluding all possible pathological causes after an exhaustive post mortem examination, and an appearance of emaciation however extreme, is not of the least value as evidence of criminal neglect

Another coroner *stated that if a doctor reported to him* that he could find no trace of injury or disease in a body and did not know the cause of death, he was satisfied that it was due to natural causes Yet another indicated that it was his practice not to order post mortem examinations in cases of bodies found in the river He simply advised the jury to return a verdict of "found drowned

Procedure at Inquests

This is often lax and irregular I know of one coroner in a large town who always calls the same jury, and if he is not sure that they are going to return the verdict he wants he *retires with them in order to assist them to arrive at it* Another coroner was shown in evidence given before the committee to have been in the habit of holding private inquiries on oath without a jury

The "view" is another relic of antiquity It was originally necessary to establish the fact that there was actually a body *whose death was to be investigated Now it is* useless and disagreeable It is urged that it enables the coroner and jury better able to follow the medical evidence But this can only apply in the case of wounds, and to be of any value the jury should see, not only the surface of the body, but also the injuries produced in the internal organs Its uselessness is *shown by the fact that it is not required by the magistrate or* grand or petty juries

But the greatest objection to the present system in my opinion, is the unnecessary pain it inflicts upon witnesses It is always a trying ordeal to appear at an inquest A person recently bereft of a loved one, probably under tragic circumstances, is *required to face a crowded and curious court in a* state of great distress and reveal all sorts of private and domestic details The great bulk of the cases are non-criminal, and it is difficult to see the necessity for publishing these details broadcast in the newspapers The court is open to all and sundry, and sensational cases become almost shows It is this feature of the inquest, above all, which is responsible for the non reporting of doubtful cases

The practice of requiring a body to be formally identified by a near relative is distressing and often totally unnecessary *It involves a visit to the mortuary*, where other bodies in various stages of putrescence may be lying Where there is no doubt as to the identity there seems no reason why this purely formal evidence should not be taken privately before the inquest

Proposals for Reform

We have seen that the fundamental objection to the present system is the absence of any definite result from the verdict commensurate with the pain and expense involved The inquest verdict has no legal weight and does not settle legal questions, it has frequently little scientific value and does not provide accurate medical statistics Reform should take the line of giving it weight for one or other of these purposes We cannot have both, since the modes of inquiry demanded are radically different If it be decided that the office is essentially judicial in character, then the coroner should always be a lawyer of high standing, legal procedure should be observed in his court, and he should be bound to observe the law of evidence His court should rank as one of first instance, and he alone should investigate charges of murder and manslaughter and commit for trial, no magisterial proceedings being taken in his cases In the matter of accidents he should possess the powers of a county court judge and his decision in claims for compensation should be binding until upset by a court of appeal

The other alternative is to regard the inquiry as held primarily for medical and scientific purposes, and only incidentally for the detection of crime in so far as medical knowledge can be utilised for that purpose The coroner *under this system should be a highly qualified medical man*, and his function would be to determine the pathological cause of death, leaving all legal questions to be settled by other tribunals In a case of murder or manslaughter for which a person had been arrested he would either leave the investigation entirely in the hands of the magistrate or he would take *simply medical evidence and such other evidence* as bore upon the pathological cause of death and would then send a report to the magistrate who would finish the case In a case of accident he would settle once and for all whether the condition was due to disease or injury, but he would leave all questions of responsibility, claims for compensation, and so on to the properly constituted legal tribunals The jury would not be necessary, and only representatives of the deceased, of persons concerned, and of the police should have a right to be present No account would be published in the newspapers With this simplified and semi private procedure medical practitioners would hesitate far less to report doubtful cases

It will be urged against a private inquiry that it will lead to the "hushing up of questionable cases To this I reply that it is only the hushing up of crime which matters, and with this question the medical coroner would not be dealing The only hushing up possible would be in regard to details of a pathological character, and I see no reason why it should be published abroad that a man died from syphilis or alcoholism This objection is not found in Scotland, nor, as far as I know, in France and Germany, where a private inquiry is held Finally, the present system affords no safeguard against this abuse, as was conclusively shown in evidence before the Departmental Committee

Certification of Death

Of the two courses I have outlined my own view is that [illegible] with it should [illegible] tifying deaths [illegible] of investigating generally the causes of death from the scientific point of view hinders the progress of medicine, and renders social legislation based upon medical statistics difficult and uncertain It is just the deaths in which the pathology is obscure that would yield the most valuable information, and every day cases which would furnish knowledge of great [illegible] lost Further, the system [illegible] to the relatives naturally [illegible] terminology hiding the [illegible] s where it reflects upon the character of the deceased We know that in such matters consisting of a lay coroner and a jury of working men is competent to determine the highly scientific questions involved, and Sir Frederic Hewitt in his evidence before the Coroner's Committee stated that the true facts are often not brought out. I have now records of some hundreds of such inquests, and in all of them the jury found that the anæsthetic had been properly administered. This seems to indicate either that the risk of negligent administration is so slight that the inquiry is superfluous or, more probably, that the tribunal is incapable of detecting faulty procedure. It is amusing to note the differences of view among coroners as to the effect of these inquests upon the public. The coroner for Manchester said: "The one thing I do deprecate is not the inquest, but publicity. In my practice I endeavour as far as possible to keep these matters quiet, to keep them from the public for the sake of other patients." The coroner for Birmingham stated: "One of the objects I think of holding an inquest is to maintain public confidence in the medical profession and medical institutions, and I think it does maintain that confidence for people to feel when a death occurs under such circumstances that it is inquired into and you can always put it to a jury."

Mr. Pepper in his evidence before the Departmental Committee stated that he had seen coroners go wrong many times over the medical evidence, and scattered through the volumes of the report are numerous instances where coroners have failed to appreciate the medical points. One coroner in a case of starvation attached great importance to the viewing of the body by the jury. He said: "The evidence given at the inquest to uneducated minds without having seen the body would have conveyed very little . . . having seen the body of the old woman with the bones almost through her skin, the jury immediately formed their own opinion outside the oral evidence and found a verdict of manslaughter." He was asked if he thought proceedings would not have been taken if the jury had not seen the body, and replied: "I am perfectly sure they would not, as I heard it said, 'What an absurd thing to bring in a verdict of manslaughter.' I have not the slightest doubt that that woman was convicted purely on the viewing of the body." It is clear that such a case ought to turn solely on the medical evidence. Starvation can only be proved by excluding all possible pathological causes after an exhaustive post-mortem examination, and an appearance of emaciation however extreme, is not of the least value as evidence of criminal neglect.

Another coroner stated that if a doctor reported to him that he could find no trace of injury or disease in a body and did not know the cause of death, he was satisfied that it was due to natural causes. Yet another indicated that it was his practice not to order post-mortem examinations in cases of bodies found in the river. He simply advised the jury to return a verdict of "found drowned."

Procedure at Inquests.

This is often lax and irregular. I know of one coroner in a large town who always calls the same jury, and if he is not sure that they are going to return the verdict he wants he retires with them in order to assist them to arrive at it. Another coroner was shown in evidence given before the committee to have been in the habit of holding private inquiries on oath without a jury.

The "view" is another relic of antiquity. It was originally necessary to establish the fact that there was actually a body whose death was to be investigated. Now it is useless and disagreeable. It is urged that it enables the coroner and jury better able to follow the medical evidence. But this can only apply in the case of wounds, and to be of any value the jury should see, not only the surface of the body, but also the injuries produced in the internal organs. Its uselessness is shown by the fact that it is not required by the magistrate or grand or petty juries.

But the greatest objection to the present system in my opinion, is the unnecessary pain it inflicts upon witnesses. It is always a trying ordeal to appear at an inquest. A person recently bereft of a loved one, probably under tragic circumstances, is required to face a crowded and curious court in a state of great distress and reveal all sorts of private and domestic details. The great bulk of the cases are non-criminal, and it is difficult to see the necessity for publishing these details broadcast in the newspapers. The court is open to all and sundry, and sensational cases become almost shows. It is this feature of the inquest, above all, which is responsible for the non-reporting of doubtful cases.

The practice of requiring a body to be formally identified by a near relative is distressing and often totally unnecessary. It involves a visit to the mortuary, where other bodies in various stages of putrescence may be lying. Where there is no doubt as to the identity there seems no reason why this purely formal evidence should not be taken privately before the inquest.

Proposals for Reform.

We have seen that the fundamental objection to the present system is the absence of any definite result from the verdict commensurate with the pain and expense involved. The inquest verdict has no legal weight and does not settle legal questions; it has frequently little scientific value and does not provide accurate medical statistics. Reform should take the line of giving it weight for one or other of these purposes. We cannot have both, since the modes of inquiry demanded are radically different. If it be decided that the office is essentially judicial in character, then the coroner should always be a lawyer of high standing, legal procedure should be observed in his court, and he should be bound to observe the law of evidence. His court should rank as one of first instance, and he alone should investigate charges of murder and manslaughter and commit for trial, no magisterial proceedings being taken in his cases. In the matter of accidents he should possess the powers of a county court judge and his decision in claims for compensation should be binding until upset by a court of appeal.

The other alternative is to regard the inquiry as held primarily for medical and scientific purposes, and only incidentally for the detection of crime in so far as medical knowledge can be utilised for that purpose. The coroner under this system should be a highly qualified medical man, and his function would be to determine the pathological cause of death, leaving all legal questions to be settled by other tribunals. In a case of murder or manslaughter for which a person had been arrested he would either leave the investigation entirely in the hands of the magistrate or he would take simply medical evidence and such other evidence as bore upon the pathological cause of death and would then send a report to the magistrate who would finish the case. In a case of accident he would settle once and for all whether the condition was due to disease or injury, but he would leave all questions of responsibility, claims for compensation, and so on, to the properly constituted legal tribunals. The jury would not be necessary, and only representatives of the deceased, of persons concerned, and of the police should have a right to be present. No account would be published in the newspapers. With this simplified and semi-private procedure medical practitioners would hesitate far less to report doubtful cases.

It will be urged against a private inquiry that it will lead to the "hushing up" of questionable cases. To this I reply that it is only the hushing up of crime which matters, and with this question the medical coroner would not be dealing. The only hushing up possible would be in regard to details of a pathological character, and I see no reason why it should be published abroad that a man died from syphilis or alcoholism. This objection is not found in Scotland, nor, as far as I know, in France and Germany, where a private inquiry is held. Finally, the present system affords no safeguard against this abuse, as was conclusively shown in evidence before the Departmental Committee.

Certification of Death.

Of the two courses I have outlined, my own view is that [illegible] with it should [illegible] tifying deaths [illegible] of investigating generally the causes of death from the scientific point of view hinders the progress of medicine, and renders social legislation based upon medical statistics difficult and uncertain. It is just the deaths in which the pathology is obscure that would yield the most valuable information, and every day cases which would furnish knowledge of great [illegible] lost. Further, the system [illegible] to the relatives naturally [illegible] terminology hiding the [illegible]s where it reflects upon the character of the deceased. We know that in such matters

THE PSYCHOLOGY OF THE MILITANT SUFFRAGETTE.

To the Editor of The Lancet.

Sir,—I do not propose to consider the question of the propriety of extending the parliamentary franchise to women, my object is to arrive at a conclusion on the mental state of those women who commit acts of violence in opposition to the law of the country

Many people who see that women commit arson, manufacture and use bombs, break windows, and starve themselves for the sake of the idea that by so doing they will get what they want, come to the conclusion that these persons must be insane because lunatics may act in the same way The inference is illogical, because the acts of the insane, similar though they may be in kind to those of the militant suffragettes, spring from a different class of motive (as a rule) and though the working out into action is the same, whether the idea be a sane or an insane one, it is the nature of the motive which makes the difference There are amongst the large body of suffragettes many who happen to be insane or weak minded—I have seen them —but the same statement applies to all other sections of people, it is an accident and is not a necessary cause of the conduct in question The actions of the insane are the impulsive or the deliberate working out of their false ideas, and the result generally shows the invalidity of the motive, but the militant suffragette has in many particulars justified her actions She has gone on hunger strike and has been successful in procuring the abandonment of artificial feeding and in getting the term of her imprisonment shortened, and by her polemic measures she has made many think that the best way of pacifying her is by treating her as a naughty child and giving her all she wants There is no evidence of insanity in this—on the contrary, it has all the characteristics of very sane procedure Nor does it help us to say that if not actually insane they are, at any rate the victims of hysteria I have endeavoured elsewhere (Ex Cathedrâ Essays) to show that in hysteria "there is an organic change at the root of the condition, defective or perverted action of the higher nervous and mental states," and though some may be in this condition by accident it is by no means a necessary explanation of the acts of these women who are neither insane nor hysterical These actions, however they may be condemned as inimical to the sense and feeling of the general community, are not, *quâ* actions, wrong, they are but the correct interpretation of certain central conditions, and it is these latter to which attention must be turned

Few people know the importance of feeling in volitional acts, but it is, as a fact, one of the most important essentials, and both feeling and emotion are strongly developed elements of the female mind So is mono ideism or the concentration of consciousness on some subject carrying with it a very strong emotional tone, such as, in its extreme development, is seen in the state called ecstasy, which though a rare, is not an insane, condition In an elaborate argument Wundt shows that *personal character* is the ultimate cause of volition and that the connexion between motive and volition is uncertain because of the existence of this personal factor, the manner of whose coöperation with external factors is unknown The real nature of personality is a riddle What causes women to commit these voluntary and impulsive (also to some extent voluntary) actions is their personal factor their character; and of the proper nature of this character men are comparatively ignorant, just as women have shown themselves ignorant of the character of men Up to recent times our knowledge of the real character of women was very imperfect—it is still far from complete, and it never will be absolutely full, but recent events have made it clear that the personal factor contains elements of an intensity and range hitherto unappreciated, and we have been astonished at what has been seen, though still allowing that further developments of action will probably widen our knowledge And just as men have under estimated the emotional strength and intensity of concentrated ideism in women, so have women been—and still are—mistaken in their estimate of the character of men Until it is evident to them that their efforts to obtain what they want by violent means are ineffectual they will pursue their present tactics When they find that men are not to be beaten into compliance they will stop their futile practices, not before Meanwhile, as long as the present attitude of the male element lasts the war of the sexes must continue Individual men are found to justify the action of the militants, but they are neither strong nor numerous enough to influence the personality of the majority Whether eventually the oscillations of thought of the community will change or turn is a question of the future The militants have just as much right to think the male elements insane for not granting their (to them) reasonable views, as the men have to make the charge of insanity against women for acting in a way which denotes obstinate ignorance and nothing more

Up to recent times women were said to be "better" than men—morally that is It now appears that there is not so much virtuous difference as they were credited with, for we are having practical displays of revenge, spite, and all the embodiments of what is generally called "devilry" Women have from time to time shown how far strong emotion will lead them, and to what actions concentration upon a single idea (with its accompanying emotional tone) will commit them, but men did not recognise how general throughout the sex was this mental trend Now that we do recognise it we are surprised at nothing they do nor at their ingenuity in devising fresh modes of irritation Personal character is the true cause of volition, it acts of necessity, whereas motives may or may not determine volition, and so some suffragettes are prompted to militancy, others are not, according to the development of this personal factor

Prison discipline forcible feeding, &c, will not alter the personal factor in women (which is founded on innate strong feeling) because they perceive that the male governing body is not competent to carry out its programme to its ultimate consequences—i e, to let them starve and die—and therefore the hope still remains that in the long run they will win And so the contest will go on until one side or the other is tired of fighting, until the personal factor is changed and the individual will becomes the general will

Crime is often due to mistakes on the part of the individual, he pits his cleverness against that of the community, and he takes every possible care that he may not be found out For a time he may be successful, and so he goes on until he finds that society is too clever for him, and therein lies his original mistake, he is caught and imprisoned The militant suffragette is much the same Her crime is founded on her non comprehension that men do not intend to give her what she wants, but when she is found out in her criminal acts and is sent to prison she discovers that by a strong display of personal character in refusing food and enduring the resultant bad health she obtains her discharge, so that punishment only confirms her idea that the remedy for her wrongs is in her own hands, and that she will ultimately compel men to change their personal factor as it stands at present Herein lies her mistake in all probability Anyhow, the tactics of these recalcitrant women have given a rude shock to the belief in the irrevocability of criminal sentences, and one wonders what will happen if men copy the women in their abstention from food and drink Would they have the same consideration shown to them, or would they be allowed to die in the obscurity of unadvertised and neglected confinement?

I am Sir, yours faithfully,

MEDICINE AND PSYCHOLOGY.

To the Editor of THE LANCET.

SIR,—Certain aspects of modern psychology have been presented in your columns recently

May I draw attention to the following? In Dr W. McDougall s lucid introduction to Psychology in the Home University Library he defines psychology as "the positive science of the behaviour of living things To accept this definition is to return to the standpoint of Aristotle, and to set out from generally recognised facts, unprejudiced by theories "

From the standpoint of this definition there is evidently a very wide field of investigation open to psychology to day And in considering some of the problems with which we in the medical profession are confronted there seems special need to maintain a balanced judgment as free from bias as possible A hasty process of deduction can be of little use in this respect, and the slower and surer method of induction would appear to be more hopeful of fruitful results To quote Bacon —

> Man being the servant and interpreter of Nature, can do and understand so much and so much only as he has observed in fact or in thought of the course of nature (in naturæ ordine re vel mente observaverit) beyond this he neither knows anything nor can do anything —(Novum Organum: Aphorism 1)
>
> [illegible]

And to carry the principle a step further—into the realm of psychotherapy—I cannot help thinking that its application will prove both illuminative and fruitful

There is ample material at hand in practical results which have already been achieved in England, America and on the Continent And these results bear intimately upon general practice as well as upon some of its special departments

> Even if the breath of hope which blows on us from that New Continent were fainter than it is and harder to perceive, yet the trial (if we would not bear a spirit altogether abject) must by all means be made there is hope enough and to spare not only to make a bold man try but also to make a sober minded and wise man believe —(Aphorism 114)

NECROSIS IN ECLAMPSIA

To the Editor of THE LANCET

SIR,—I have read with much interest the paper by Professor R Jardine and Dr A M Kennedy[1] on symmetrical necrosis of the cortex of the kidney in eclampsia, and more particularly the two tentative conclusions of the latter—namely, that he is "inclined to the view that the cause of the necrosis in the kidneys is the same as that which causes the necrosis in the liver" and that "the thrombosis in the smaller cortical renal arteries is secondary to the necrosis of the cells " Dr Kennedy then asks what it is that initiates the necrosis and submits that it is some factor in the eclamptic toxin I am very glad to agree with him, but hope that it may be possible to go a little further and to define this factor more closely

My own observations on necrosis in eclampsia have been confined to the liver, where alone have I seen it In previous communications[2] I have strongly urged that this necrosis is largely if not entirely due to hæmagglutinative thrombi—that is to say, to an actual occlusion of the vessels with massed red cells without the intervention of fibrin That these occur in the livers of eclamptic cases has been demonstrated by Flexner, Welch, and myself Further, Pearce has shown that an experimentally induced hæmagglutination is capable of causing a focal necrosis of liver cells and has very clearly proved the interrelation of this hæmagglutinative with a hæmolytic element in the production or prevention of necrosis The full references will be found in my papers quoted

It appears that this hæmagglutination occurs most readily where the circulation is very slow, and although such thrombi have not to my knowledge been described experimentally in the kidney, still the site of the focal necrosis as given by all writers on this form of renal destruction is much in favour of such an origin It would be extremely interesting and important to learn from Dr Kennedy whether any appearances of this nature are to be seen in the third and earliest of the three cases now reported In the microscopical report of one of the two livers examined Dr Kennedy comments on the very great dilatation of the capillaries that was present This may be similar to the extreme congestion noted by Pearce in his experimental work before the onset of necrosis

In conclusion, I have to congratulate Professor Jardine on his unique experience of six cases of this very rare condition

I am, Sir, yours faithfully,
H LEITH MURRAY.

Liverpool, May 13th, 1913

ARTIFICIAL PNEUMOTHORAX — AND AFTER? THE MECHANICAL FACTOR IN THE TREATMENT OF PHTHISIS PULMONALIS

To the Editor of THE LANCET

SIR,—In view of the organic change which within the past 12 months has radically modified the conditions of our professional existence, it is necessary to review our relation to the problem of consumption, which we are now under contract to cure Henceforth not only have we a responsibility to pathology and therapeutics, we are responsible also to the State, which, now judge as well as paymaster, is an interested partner in our pathological and therapeutical problems not alone financially, but under a conscience clause It has undertaken the welfare of the population, hitherto from time immemorial under our sole charge, and it stands committed not to deny to any individual under the rates the genuine cure We can no longer escape a categorical statement of the endorsable value of our therapeutical assets Our pathology is monumental How much longer must it remain ornamental? As to our therapy, having discarded for a while the entire pharmacopœia, we are reduced to a game of battledore and shuttlecock between syringe and sanatorium It is enough for a fair critic that Batty Shaw is still unconvinced by the one while Wilkinson still distrusts the other The sanatorium is at best a mere preventorium—opens its doors to every earliest case, yet how many are still discharged with progressive phthisis! Tuberculin scorns it, and bargains for "neither too late nor too early " Yet within that interval of its own selection it fails more often than not

How much longer shall we wait for the authoritative jury which ought to decide between fact and opinion? Meanwhile, is it not time to resume our premicrobic consultations in the grotto, where Bodington left them, and to question Nature once more whether there might not be some other cure elsewhere? Forlanini had consulted her in 1882, just within the bacillary era, but eight years before bacteriotherapy had shed its elytra "Is it to be excision or artificial pneumothorax"? The surgical proposition was pre-Listerian, and therefore problematic The other was well supported by solid fact, ripe for discussion, but seemingly incapable of it in a microbic atmosphere, except by him alone, yet brilliantly acted upon in 1885 by W Cayley, in England, so slow to follow up his pioneer operation, although Carson long before had laid an experimental foundation for it Forlanini's non bacillary, mechanical cure was a singular instance of a method arising *d'emblée*, the offspring of a master thought, in full panoply and ready for immediate action, but too heroic, too magnificent, for practical tactics, fraught with limiting risks greater than have yet been registered, and therefore bound to pass away as ineligible for the universal cure yet imperishable in its teachings, which I venture to believe contain that cure At the latest hour, when the profession, and in this country the State, are pressing for a decisive answer, it has cut the Gordian knot, and it now demonstrates to us that there is a cure elsewhere—the cure of Piorry (1833), the cure of Freund (1858) the cure of Forlanini (1882), and that that cure, though this had not been hitherto specified categorically nor yet perhaps thoroughly realised, is the mechanical cure

---

MEDICINE AND PSYCHOLOGY.

To the Editor of THE LANCET.

SIR,—Certain aspects of modern psychology have been presented in your columns recently

May I draw attention to the following? In Dr W. McDougall's lucid introduction to Psychology in the Home University Library he defines psychology as "the positive science of the behaviour of living things To accept this definition is to return to the standpoint of Aristotle, and to set out from generally recognised facts, unprejudiced by theories"

From the standpoint of this definition there is evidently a very wide field of investigation open to psychology to day And in considering some of the problems with which we in the medical profession are confronted there seems special need to maintain a balanced judgment as free from bias as possible A hasty process of deduction can be of little use in this respect, and the slower and surer method of induction would appear to be more hopeful of fruitful results To quote Bacon —

> Man being the servant and interpreter of Nature, can do and understand so much and so much only as he has observed in fact or in thought of the course of nature (To naturæ ordine re vel mente observaverit) beyond this he neither knows anything nor can do anything —(Novum Organum: Aphorism 1)

> [illegible]

And to carry the principle a step further—into the realm of psychotherapy—I cannot help thinking that its application will prove both illuminative and fruitful

There is ample material at hand in practical results which have already been achieved in England, America and on the Continent And these results bear intimately upon general practice as well as upon some of its special departments

> Even if the breath of hope which blows on us from that New Continent were fainter than it is and harder to perceive, yet the trial (if we would not bear a spirit altogether abject) must by all means be made there is hope enough and to spare not only to make a bold man try but also to make a sober minded and wise man believe —(Aphorism 114)

I am, Sir, yours faithfully,

HERBERT SHORE

NECROSIS IN ECLAMPSIA

To the Editor of THE LANCET

SIR,—I have read with much interest the paper by Professor R Jardine and Dr A M Kennedy[1] on symmetrical necrosis of the cortex of the kidney in eclampsia, and more particularly the two tentative conclusions of the latter—namely, that he is "inclined to the view that the cause of the necrosis in the kidneys is the same as that which causes the necrosis in the liver" and that "the thrombosis in the smaller cortical renal arteries is secondary to the necrosis of the cells" Dr Kennedy then asks what it is that initiates the necrosis and submits that it is some factor in the eclamptic toxin I am very glad to agree with him, but hope that it may be possible to go a little further and to define this factor more closely

My own observations on necrosis in eclampsia have been confined to the liver, where alone have I seen it In previous communications[2] I have strongly urged that this necrosis is largely if not entirely due to hæmagglutinative thrombi—that is to say, to an actual occlusion of the vessels with massed red cells without the intervention of fibrin That these occur in the livers of eclamptic cases has been demonstrated by Flexner, Welch, and myself Further, Pearce has shown that an experimentally induced hæmagglutination is capable of causing a focal necrosis of liver cells and has very clearly proved the interrelation of this hæmagglutinative with a hæmolytic element in the production or prevention of necrosis The full references will be found in my papers quoted

It appears that this hæmagglutination occurs most readily where the circulation is very slow, and although such thrombi have not to my knowledge been described experimentally in the kidney, still the site of the focal necrosis as given by all writers on this form of renal destruction is much in favour of such an origin It would be extremely interesting and important to learn from Dr Kennedy whether any appearances of this nature are to be seen in the third and earliest of the three cases now reported In the microscopical report of one of the two livers examined Dr Kennedy comments on the very great dilatation of the capillaries that was present This may be similar to the extreme congestion noted by Pearce in his experimental work before the onset of necrosis

In conclusion, I have to congratulate Professor Jardine on his unique experience of six cases of this very rare condition

I am, Sir, yours faithfully,

H LEITH MURRAY.

ARTIFICIAL PNEUMOTHORAX — AND AFTER? THE MECHANICAL FACTOR IN THE TREATMENT OF PHTHISIS PULMONALIS

To the Editor of THE LANCET

SIR,—In view of the organic change which within the past 12 months has radically modified the conditions of our professional existence, it is necessary to review our relation to the problem of consumption, which we are now under contract to cure Henceforth not only have we a responsibility to pathology and therapeutics, we are responsible also to the State, which, now judge as well as paymaster, is an interested partner in our pathological and therapeutical problems not alone financially, but under a conscience clause It has undertaken the welfare of the population, hitherto from time immemorial under our sole charge, and it stands committed not to deny to any individual under the rates the genuine cure We can no longer escape a categorical statement of the endorsable value of our therapeutical assets Our pathology is monumental How much longer must it remain ornamental? As to our therapy, having discarded for a while the entire pharmacopœia, we are reduced to a game of battledore and shuttlecock between syringe and sanatorium It is enough for a fair critic that Batty Shaw is still unconvinced by the one while Wilkinson still distrusts the other The sanatorium is at best a mere preventorium—opens its doors to every earliest case, yet how many are still discharged with progressive phthisis! Tuberculin scorns it, and bargains for "neither too late nor too early" Yet within that interval of its own selection it fails more often than not

How much longer shall we wait for the authoritative jury which ought to decide between fact and opinion? Meanwhile, is it not time to resume our premicrobic consultations in the grotto, where Bodington left them, and to question Nature once more whether there might not be some other cure elsewhere? Forlanini had consulted her in 1882, just within the bacillary era, but eight years before bacteriotherapy had shed its elytra "Is it to be excision or artificial pneumothorax"? The surgical proposition was pre-Listerian, and therefore problematic The other was well supported by solid fact, ripe for discussion, but seemingly incapable of it in a microbic atmosphere, except by him alone, yet brilliantly acted upon in 1885 by W Cayley, in England, so slow to follow up his pioneer operation, although Carson long before had laid an experimental foundation for it Forlanini's non bacillary, mechanical cure was a singular instance of a method arising *d'emblée*, the offspring of a master thought, in full panoply and ready for immediate action, but too heroic, too magnificent, for practical tactics, fraught with limiting risks greater than have yet been registered, and therefore bound to pass away as ineligible for the universal cure yet imperishable in its teachings, which I venture to believe contain that cure At the latest hour, when the profession, and in this country the State, are pressing for a decisive answer, it has cut the Gordian knot, and it now demonstrates to us that there is a cure elsewhere—the cure of Piorry (1833), the cure of Freund (1858) the cure of Forlanini (1882), and that that cure, though this had not been hitherto specified categorically nor yet perhaps thoroughly realised, is the mechanical cure

THE MEDICAL PROFESSION AND THE NATIONAL INSURANCE ACT.

To the Editor of THE LANCET.

SIR,—You kindly published recently a letter from the National Medical Guild in which attention was called to the fact that treatment by quacks, herbalists, and others was being permitted under the "own arrangements" clause of the National Insurance Act. May we be further permitted to state that the London Insurance Committee is prepared (on the evidence of its chairman given in the House of Commons recently) to allow arrangements to be made with "homœopaths and herbalists," and this in spite of the fact that Form 43 I.C., on which application to make "own arrangements" must be made, contains the statement that "the Committee will also require to be satisfied that the treatment obtained will be of a nature, quality, and extent not inferior to that obtained under the panel system."

The Parliamentary representative of the Insurance Commissioners—namely, Mr. Masterman—has made it clear that the matter is one for the discretion of the Committees, and one which he did not feel disposed to take up. Seeing that this has been a bone of contention in Germany and other continental countries, it is well that the profession in England should take the matter in hand as early as possible, and the first step to this is to understand it fully. We would therefore ask you to be so good as to give publicity to this letter. I am, Sir, yours faithfully,

GORDON R. WARD
(for the National Medical Guild)
34, Villiers street, W.C., May 6th, 1913.

MEDICAL DEFENCE UNION.—The annual general meeting of the Union will be held on May 29th, at 4 P.M., at New London Hotel, Exeter, when the usual statutory resolutions will be placed before the members, together with the annual report and balance sheet.

SWANSEA HOSPITAL.—The accommodation at the Swansea General and Eye Hospital has been materially increased by the completion of a new block which was opened on May 3rd by Lady Mond The building is three storeys high, and on the ground floor there are a new dispensary and waiting-rooms and a large waiting hall, leading out of which are four casualty wards, dressing-rooms, bathrooms, and a porter's room. On the first floor are a 12-bed ward, to be called the Patti Ward, and a two-bed ward, the cost and maintenance of which are being borne by Mr. Roger Beck. On the second floor there is accommodation for 14 patients. On each of the two upper floors are nurses' kitchens, bathrooms, &c. The cost of this block is about £13,000, and is the first instalment of a general scheme of enlargement decided upon in 1911, which it was [illegible] £30,000. A legacy

32 patients. The hospital was established as long ago as 1817, but the first portion of the present buildings was opened in 1869. Among the first subscribers was Miss Florence Nightingale who advised the promoters in the arrangement of the institution. In 1876 a second wing was completed, when the accommodation was raised to 130 beds. In 1889 the special eye department was provided, and other additions have been made from time to time, including an operating theatre. That the present extension is necessary there can be little doubt, for the population of Swansea has increased from 70,000 in 1879 to 115,000 at the present time.

MEDICAL PRACTICE UNDER THE INSURANCE ACT.

(BY OUR SPECIAL COMMISSIONER.)

(Continued from p. 1270.)

IX.—RURAL PRACTICE IN SCOTLAND.

How the Act Assists the Well-to-do Resident.

MILNGAVIE, a village on the outskirts of Glasgow, with an estimated population of 3481 persons, is in the centre of farm-land. I went there to see how the Act worked in what was represented to me as being a typical rural centre, and found three similar districts adjoining each other with seven practitioners between them. All seven practitioners are on the panel, and their work overlaps. They are, I was informed, on the panel not from choice but from necessity. It was, they considered, their only course in the circumstance in which they were placed. They were too near to Glasgow, where there might be a large supply of medical men from whom assistance could have been obtained by the Local Committee if they had attempted any strenuous resistance. Moreover, they felt that they did not know how the new Act would work. Thus a practitioner at Bearsden, one of the three districts, did not imagine he would have more than a dozen or two insured persons on his list. To his great surprise he found something like 500 names; yet this is a purely residential district, where everyone hitherto had paid the usual fees and there had been no clubs and no contract work. In such a neighbourhood it did not seem possible that 500 persons would be insured under the Act, and that no less than that number should appear on one practitioner's list was entirely contrary to expectation. It was soon apparent that these insured persons were youths and young women, the grown-up children of his well-to-do patients, who were occupied as office boys, clerks, or typists in their father's business or in the businesses of friends. Formerly, if any of these young folk fell ill, their parents paid full fees for medical attendance. Now they are all insured, and the question is whether the 500 yearly payments will represent a larger sum than the occasional but full fees formerly received This is a matter that concerns the nation as well as the patients and their medical attendants. It means that the community, by its representative the State, is now paying 2*d.* a week towards the cost of sick allowance, medicine, and medical attendance for the children of well-to-do families, who formerly met the whole of this outlay out of their own private resources. In the past such a call on their purses was considered no hardship, and the question arises whether it is right to tax the whole community so as to provide 2*d.* a week for each of these sons and daughters of well-to-do families. Though this matter was brought to my notice in regard to the residential district of Bearsden it applies to the country at large. I am sure that the same point must arise in many districts, and when in the course of my tour my attention is again brought to it I shall be able to deal with it in a few words, and avoid needless repetitions, if I refer my readers to the conditions at Bearsden.

How the Act Assists the Farmer.

It is not only the children of prosperous business men who profit by the Act to get a State contribution in the event of illness. At the other end of the social scale the agricultural labourers are also adding to public expenditure. Undoubtedly if the State should aid individuals to insure against sickness none are more deserving of such assistance than agricultural labourers. But the matter does not work out exactly in this way. It is the farmer who receives State aid, and however much the British farmer may require State subsidy in his present somewhat anxious position, it was not the intention of the National Insurance Act to afford it. In Scotland there has been so much emigration that agricultural labour is hard to obtain, and the wages paid are much higher than in England. A labourer easily obtains 15*s.* a week besides his board and lodging on the farm, and hitherto medical attendance has been included. The farmer paid for the medical attendance upon his men, and not only paid full fees, but, if he sold milk, he very frequently sent for the doctor. It is absolutely necessary that the farmer should guard himself from the risk of *as a ground for divorce, not as a punishment, but in the* interests of the sane spouse and children and countless generations to come. It matters not whether it was or was not the lunatic's fault that he is insane; in either case it is deplorable, and should evoke our deepest sympathy for everybody concerned; but we have to consider the spouse and family thus bereft of an important member and the illimitable suffering of future generations.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Health of the City.

THE report of the medical officer of health for the first quarter of this year states that the population of the city is estimated at 859,644, an increase of 8697 as compared with the first quarter of last year. The number of births was 5761, or 26·9 per 1000. There were 3544 deaths, equal to 16·5 per 1000, as compared with 16·2 last year. The death-rate, whilst only slightly higher than last year, was considerably higher than in 1910 and 1911, when it was 15·2 in the same quarter. There were 750 deaths of infants under one year old, about one-fifth of the whole number. On the other hand, there were 335 deaths of persons between 75 and 85, and 73 deaths over 85, including 1 death at 110 years. The following show the deaths from infectious diseases: enteric fever, 6; small-pox, 0; measles, 275; scarlet fever, 55; whooping-cough, 16; diphtheria, 44; pulmonary tuberculosis, 306; and other forms of tuberculosis, 64. The number of notifications received were: enteric fever, 25; scarlet fever, 1714; diphtheria, 219; erysipelas, 184; pulmonary tuberculosis, 1225; other forms of tuberculosis, 385; cerebro-spinal fever, 1; poliomyelitis, 1; puerperal fever, 24; and ophthalmia neonatorum, 54. Teachers in elementary schools reported 2672 cases of measles, 227 of whooping-cough, and 1347 cases of mumps. The number of cases of scarlet fever was exceptionally large, the nearest approach being 1389 in 1902, but both scarlet fever and measles showed a decline as compared with the last quarter of 1912.

The City Analyst's Report.

Last year 4136 samples were submitted for analysis, and of these 7·9 per cent. were found to be adulterated. Of 1616 samples of milk 4 contained boric acid, 6 saltpetre, and 132 contained added water or were deficient in fat, the percentage of adulteration being 8·2. Over 1000 samples of butter were examined, and 5·1 per cent. were found adulterated. With regard to margarine, the report observes that it is unfortunate the law does not require that each pound-roll of margarine when packed in a box should be marked "margarine." If this were so honest vendors could not make mistakes, and a further difficulty would be put in the way of dishonest ones. At present only the box is marked, so that a fraudulent vendor has only to take the rolls from the box and they are ready for sale as butter. Of 30 samples of aerated waters 17 were adulterated. Referring to non-alcoholic wines, the report relates that the inspector went into a shop and asked for "non-alcoholic wine." He received a bottle labelled "ginger wine" and another labelled "orange wine." He especially asked if they were non-alcoholic and was told that they were. Analysis showed that the ginger wine contained 11·8 per cent. of absolute alcohol and the orange wine 10·0 per cent. Of 143 samples of drugs 28 from 15 different vendors were found to be impure.

Medical Men and the Royal Army Medical Corps (T.).

At a meeting of the Warwickshire Territorial Association the difficulties in the way of medical men joining the Royal Army Medical Corps Units were considered, and it was resolved that representation should be made to the War Office. Apparently the demands upon the time of medical men who have joined the panel are so great that they are unable to give the time to ambulance work, and difficulty is arising in finding the number of officers required.

Health Week.

Much interest has been taken in the city in the health propaganda of the last week. Two large meetings were held in the town-hall. At the first the Lord Mayor presided, and a lecture was given by Dr. J. Robertson, the medical officer of health, on the "Better Birmingham of the Future," with special reference to its works and workers. The work of the health committee was described and the lines upon which future reforms should proceed. At the second meeting Alderman Fletcher, the chairman of the health committee, presided, and Mr. Gilbert Barling gave an address full of practical advice to workers upon the care of their health. Lectures were given every evening in various council schools, sermons were preached in most of the churches, and addresses were given in the adult schools and elsewhere. The adult schools are continuing their campaign against consumption, begun last summer when the Anti-Tuberculosis Exhibition visited Birmingham. It was realised that this exhibition, although attended by a very large number of people, did not reach many in the poorest parts of the city. The adult schools are, therefore, holding exhibitions on a smaller scale in the poorer quarters, and lectures are given by medical men and city councillors.

The Children's Hospital.

On April 23rd H.R.H Princess Louise, accompanied by the Duke of Argyll, laid the foundation stone of the new buildings and unveiled the statue of King Edward VII. The new hospital and statue form the King Edward VII. Memorial provided by public subscriptions. The sum subscribed was £32,808, and of this £2700 have been expended upon the statue. The total cost of the building and furnishing of the hospital is estimated at £62,000. The amount in the hands of the committee being £49,000, a further sum of £13,000 is required.

May 7th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Conference of Scottish School Medical Officers.

THIS conference took place in the Heriot-Watt College, Edinburgh, on May 1st and 2nd, Dr. Carstairs C. Douglas, principal lecturer in hygiene to Glasgow Provincial Committee, being in the chair. Dr. W. Leslie Mackenzie delivered an opening address on the Social Significance of Medical Inspection; Dr. A. Campbell Munro read a paper on the Hygiene of the School; Dr. George Rose discussed the opportunities afforded for medical research by school inspection. After a visit to Dunfermline to witness the fullest development of medical inspection, including the College of Hygiene and Physical Training, where students became qualified as teachers, Dr. L. D. Cruickshank gave an [illegible] Organisation of Physical Education as an [illegible]. On the [illegible] Inspector [illegible] a brief address by Sir John Struthers, K.C.B., in which he dwelt on the importance of school medical inspection and the need for coöperation of medical officers and inspectors, Dr. Alister T. Mackenzie, administrative medical officer of the Carnegie [illegible] Training Profession. Dr. Isabella D. Cameron then read a paper by Dr. Darling, medical officer of the Edinburgh Provincial Committee, in which some typically difficult cases that come under the medical examination of candidates in the teaching profession were discussed. In the afternoon Dr. James Ritchie presided, and Dr. J. Halley Meikle read a paper on Medical Treatment in Towns, and Dr. J. Maxwell Ross one on Medical Treatment in the Counties.

Medical Inspection of Children in Scotland.

The Committee of Council on Education in Scotland have issued a minute requiring that the medical inspection of children in schools within the area of every school board shall be conducted in accordance with the regulations embodied in the Department's memorandum on the medical inspection and supervision of school children bearing the date March 31st, 1909; also that in cases where such inspection is not provided for under a scheme approved of by Section 17 (6) of the Education (Scotland) Act, 1908, it should be conducted by a medical practitioner who (*a*) holds the Diploma in Public Health or possesses other qualifications which are accepted by the Department as equivalent thereto, or (*b*) is not engaged in private practice. It is also stated that nothing in the minute shall prejudice the right of any school board to institute a supplementary scheme of medical inspection for the children attending schools within their district, provided that any such supplementary scheme has been submitted beforehand to the Department for approval.

On the other hand, there were 335 deaths of persons between 75 and 85, and 73 deaths over 85, including 1 death at 110 years. The following show the deaths from infectious diseases: enteric fever, 6; small-pox, 0; measles, 275; scarlet fever, 55; whooping-cough, 16; diphtheria, 44; pulmonary tuberculosis, 306; and other forms of tuberculosis, 64. The number of notifications received were: enteric fever, 25; scarlet fever, 1714; diphtheria, 219; erysipelas, 184; pulmonary tuberculosis, 1225; other forms of tuberculosis, 385; cerebro-spinal fever, 1; poliomyelitis, 1; puerperal fever, 24; and ophthalmia neonatorum, 54. Teachers in elementary schools reported 2672 cases of measles, 227 of whooping-cough, and 1347 cases of mumps. The number of cases of scarlet fever was exceptionally large, the nearest approach being 1389 in 1902, but both scarlet fever and measles showed a decline as compared with the last quarter of 1912.

The City Analyst's Report.

Last year 4136 samples were submitted for analysis, and of these 7·9 per cent. were found to be adulterated. Of 1616 samples of milk 4 contained boric acid, 6 saltpetre, and 132 contained added water or were deficient in fat, the percentage of adulteration being 8·2. Over 1000 samples of butter were examined, and 5·1 per cent. were found adulterated. With regard to margarine, the report observes that it is unfortunate the law does not require that each pound-roll of margarine when packed in a box should be marked "margarine." If this were so honest vendors could not make mistakes, and a further difficulty would be put in the way of dishonest ones. At present only the box is marked, so that a fraudulent vendor has only to take the rolls from the box and they are ready for sale as butter. Of 30 samples of aerated waters 17 were adulterated. Referring to non-alcoholic wines, the report relates that the inspector went into a shop and asked for "non-alcoholic wine." He received a bottle labelled "ginger wine" and another labelled "orange wine." He especially asked if they were non-alcoholic and was told that they were. Analysis showed that the ginger wine contained 11·8 per cent. of absolute alcohol and the orange wine 10·0 per cent. Of 143 samples of drugs 28 from 15 different vendors were found to be impure.

Medical Men and the Royal Army Medical Corps (T.).

At a meeting of the Warwickshire Territorial Association the difficulties in the way of medical men joining the Royal Army Medical Corps Units were considered, and it was resolved that representation should be made to the War Office. Apparently the demands upon the time of medical men who have joined the panel are so great that they are unable to give the time to ambulance work, and difficulty is arising in finding the number of officers required.

Health Week.

Much interest has been taken in the city in the health propaganda of the last week. Two large meetings were held in the town-hall. At the first the Lord Mayor presided, and a lecture was given by Dr. J. Robertson, the medical officer of health, on the "Better Birmingham of the Future," with special reference to its works and workers. The work of the health committee was described and the lines upon which future reforms should proceed. At the second meeting Alderman Fletcher, the chairman of the health committee, presided, and Mr. Gilbert Barling gave an address full of practical advice to workers upon the care of their health. Lectures were given every evening in various council schools, sermons were preached in most of the churches, and addresses were given in the adult schools and elsewhere. The adult schools are continuing their campaign against consumption, begun last summer when the Anti-Tuberculosis Exhibition visited Birmingham. It was realised that this exhibition, although attended by a very large number of people, did not reach many in the poorest parts of the city. The adult schools are, therefore, holding exhibitions on a smaller scale in the poorer quarters, and lectures are given by medical men and city councillors.

The Children's Hospital.

On April 23rd H.R.H Princess Louise, accompanied by the Duke of Argyll, laid the foundation stone of the new buildings and unveiled the statue of King Edward VII. The new hospital and statue form the King Edward VII. Memorial provided by public subscriptions. The sum subscribed was £32,808, and of this £2700 have been expended upon the statue. The total cost of the building and furnishing of the hospital is estimated at £62,000. The amount in the hands of the committee being £49,000, a further sum of £13,000 is required.

May 7th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Conference of Scottish School Medical Officers.

THIS conference took place in the Heriot-Watt College, Edinburgh, on May 1st and 2nd, Dr. Carstairs C. Douglas, principal lecturer in hygiene to Glasgow Provincial Committee, being in the chair. Dr. W. Leslie Mackenzie delivered an opening address on the Social Significance of Medical Inspection; Dr. A. Campbell Munro read a paper on the Hygiene of the School; Dr. George Rose discussed the opportunities afforded for medical research by school inspection. After a visit to Dunfermline to witness the fullest development of medical inspection, including the College of Hygiene and Physical Training, where students became qualified as teachers, Dr. L. D. Cruickshank gave an [illegible] as an [illegible] On the [illegible] Inspector [illegible] a brief address by Sir John Struthers, K.C.B., in which he dwelt on the importance of school medical inspection and the need for coöperation of medical officers and inspectors, Dr. Alister T. Mackenzie, administrative medical officer of the Carnegie [illegible] Training Profession. Dr. Isabella D. Cameron then read a paper by Dr. Darling, medical officer of the Edinburgh Provincial Committee, in which some typically difficult cases that come under the medical examination of candidates in the teaching profession were discussed. In the afternoon Dr. James Ritchie presided, and Dr. J. Halley Meikle read a paper on Medical Treatment in Towns, and Dr. J. Maxwell Ross one on Medical Treatment in the Counties.

Medical Inspection of Children in Scotland.

The Committee of Council on Education in Scotland have issued a minute requiring that the medical inspection of children in schools within the area of every school board shall be conducted in accordance with the regulations embodied in the Department's memorandum on the medical inspection and supervision of school children bearing the date March 31st, 1909; also that in cases where such inspection is not provided for under a scheme approved of by Section 17 (6) of the Education (Scotland) Act, 1908, it should be conducted by a medical practitioner who (*a*) holds the Diploma in Public Health or possesses other qualifications which are accepted by the Department as equivalent thereto, or (*b*) is not engaged in private practice. It is also stated that nothing in the minute shall prejudice the right of any school board to institute a supplementary scheme of medical inspection for the children attending schools within their district, provided that any such supplementary scheme has been submitted beforehand to the Department for approval.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for ins[illegible] *tion, must be authenticated b* [illegible] *their writers—not necessarily* [illegible]

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs 50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—MESSRS. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated [illegible] their writers—not necessarily [illegible]

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.				TO THE COLONIES AND ABROAD.			
One Year	£1	1	0	One Year	£1	5	0
Six Months	0	12	6	Six Months	0	14	0
Three Months	0	6	6	Three Months	0	7	0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs 50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—MESSRS. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

A Presidential Address

ON

SOME INDUSTRIAL ACCIDENTS AND DISEASES.

Delivered in the Section of Industrial Hygiene at the Congress of the Royal Institute of Public Health at Paris on May 16th, 1913,

BY SIR THOMAS OLIVER, M.D. GLASG., F.R.C.P. LOND.,

PROFESSOR OF PRACTICE OF MEDICINE, UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, NEWCASTLE-UPON-TYNE.

GENTLEMEN,—A century ago factory owners, in order to increase production and have a reliable source of energy, substituted steam for water as the motive power. This was followed by industrial and social events of a far-reaching nature.

INDUSTRIAL EMPLOYMENT OF ELECTRICITY.

The replacement of steam by electricity in modern days is not less again a step in advance of that of previous decades. One effect of the replacement of water-power by steam was dislocation of industries. Factories came no longer to be built upon the banks of rural streams but in towns where labour was abundant, or in close proximity to coal-fields where fuel was cheap. One of the drawbacks to the use of coal is the smoke which is created. This shuts out sunlight and so contaminates the atmosphere as to render it less fit for breathing purposes, while it increases the susceptibility of the respiratory organs to disease. Some of the large iron manufacturing districts in England have always a high death-rate from pneumonia and acute bronchial affections. It is known that since Germany has become more industrial her mortality-rate from pulmonary diseases other than tuberculosis has markedly risen, and this, too, during a period when the number of deaths from pulmonary tuberculosis has been falling. For this rise in the mortality-rate the increasingly large volumes of smoke thrown into the atmosphere are said to be answerable. Where electricity is the motive-power in factories and on railroads the atmosphere remains clear. By substituting electricity for steam one danger at least is thus got rid of; but electricity has dangers of its own, dangers of an acute and serious nature, and so subtle in their incidence as frequently and unexpectedly to entrap the unwary.

Electrical Accidents.

We can never tell exactly what number of deaths from acute pulmonary diseases are due to the effects of smoke and fog alone, but in countries where deaths from electrical injuries are notified the number of persons killed, also the number of persons seriously injured, can be estimated. In Great Britain the number of electrical accidents occurring in generating stations during 1911 was 74, compared with 58 for 1910, the number of deaths being 4 for each year. In factories the cases numbered 290 for 1911 and 276 for 1910, the deaths being 7 in 1911 and 5 in 1910. It is interesting to note that while in Great Britain the use of electrical energy for motive-power has risen from 30,999 horse-power in December, 1902, to 774,000 in December, 1911, there has been practically speaking no increase in the number of electrical accidents since 1907. The check in the number of accidents, according to the electrical inspector of factories, followed the issue of draft regulations by which the attention of occupiers and engineers was directed to questions of safety. The numbers given refer only to accidents in factories and generating stations; for taking the number of deaths from electricity all over the country they were 29 in 1909 and 26 in 1910, only 9 of these in 1910 occurring in generating stations and factories. As bearing upon the growing application of electricity to the industrial needs of France the increasing number of persons notified as having suffered from electrical injuries is not without significance. In 1907 there were 571 persons injured; in 1908, 773; in 1909, 778; 909 in 1910; while in 1911 the numbers rose to 1027. Taking the figures for 1911, which M. Boulin, inspecteur divisionnaire de travail of Lille, has sent me, of those injured 52 died, 12 were permanently incapacitated, and 927 were temporarily indisposed; of the remainder the results are not stated. To the above must be added other 30 persons injured in connexion with mines; of these 4 died, 1 was permanently incapacitated, and 25 temporarily so.

It is no light toll which this comparatively unknown power so recently introduced into our industries is exacting from the workers. It is one in regard to the operation of which working men must be ever on their guard, for the occasions upon which electrical currents can be used will not tend [illegible] from its [illegible] it is [illegible] in [illegible] increasingly employed. Old methods of production in chemical works are disappearing, new methods into which electricity enters are taking their place, and these are not free from danger. Because the current can be readily turned on in a factory, electricity is a force of wide application. It has been used, for example, for drilling iron plates, but the electric drill has been superseded by that worked by compressed air on account of this drill being driven more rapidly and effectively.

Causation and Nature of Electrical Accidents.

Where men have succumbed to electrical shock there may be no external marks to explain the fatality. In other instances there are burns. These when present are irregular, frequently deep, and extend down to the bone. I shall not dwell at length upon the question of what pressures of electrical currents are within the limits of safety. To measure the pressure or tension of electrical currents the term "voltage" is employed, while by "ampèrage" is meant the rate of flow. "Alternating" currents are usually regarded as more dangerous than "continuous." When death has been caused by electricity the question is generally asked, What was the voltage of the live metal at the time of the accident? The influence of ampèrage ought, however, to be considered as well as voltage. Voltages above 1000 are dangerous, but Jellinek reports a fatality where the individual had been brought into contact with only 65 volts. It is the mode of contact which is the important circumstance, also the unexpectedness of the contact, for electricians can, and do, frequently touch with their hands wires carrying currents of 5000 volts and more without experiencing any serious inconvenience. Much depends upon whether at the time of contact the skin is dry or moist, whether the workman's clothes and boots are dry or not, also whether he is standing on damp earth. The thick, hard, and dry skin of a workman's hand is less favourable to the penetration of an electrical current than the delicate or moist skin of a clerk. Although intangible, electricity is a saleable product. As a commercial commodity the dangers incidental to its generation and transmission bring it within the range of industrial hygiene. A few years ago my colleague, R. A. Bolam, and myself, by a series of experiments upon animals, satisfied ourselves that death in electrical shock from continuous currents is due to arrest of the action of the heart, and that by means of artificial respiration carried on for a considerable time dogs apparently killed could be resuscitated. In a few of our experiments, just as in those of M. Prévost and M. Batelli, death came through stoppage of the breathing as well as by arrest of the heart's action. No matter how workmen have been struck by an electrical discharge with an apparently fatal result, artificial respiration is the only reliable method to adopt to restore life.

My object in alluding to the dangers incidental to electricity is not simply to point to the increasing demand for electricity in industrial concerns nor to explain how death comes, but to draw attention to an opinion which has been advanced by M. Prévost and M. J. Reverdin, of Geneva. The burning and destruction of the skin in electrical injuries have a significance which ought not to be overlooked. Burning means bad rather than good contact. Once charring and destruction of the superficial skin have taken place, resistance to further penetration of the current is increased and death is thereby possibly averted. I have seen men with severe electrical burns recover, and I have also seen death

A Presidential Address

ON

SOME INDUSTRIAL ACCIDENTS AND DISEASES.

Delivered in the Section of Industrial Hygiene at the Congress of the Royal Institute of Public Health at Paris on May 16th, 1913,

By Sir THOMAS OLIVER, M.D. Glasg., F.R.C.P. Lond.,

PROFESSOR OF PRACTICE OF MEDICINE, UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, NEWCASTLE-UPON-TYNE.

Gentlemen,—A century ago factory owners, in order to increase production and have a reliable source of energy, substituted steam for water as the motive power. This was followed by industrial and social events of a far-reaching nature.

Industrial Employment of Electricity.

The replacement of steam by electricity in modern days is not less again a step in advance of that of previous decades. One effect of the replacement of water-power by steam was dislocation of industries. Factories came no longer to be built upon the banks of rural streams but in towns where labour was abundant, or in close proximity to coal-fields where fuel was cheap. One of the drawbacks to the use of coal is the smoke which is created. This shuts out sunlight and so contaminates the atmosphere as to render it less fit for breathing purposes, while it increases the susceptibility of the respiratory organs to disease. Some of the large iron manufacturing districts in England have always a high death-rate from pneumonia and acute bronchial affections. It is known that since Germany has become more industrial her mortality-rate from pulmonary diseases other than tuberculosis has markedly risen, and this, too, during a period when the number of deaths from pulmonary tuberculosis has been falling. For this rise in the mortality-rate the increasingly large volumes of smoke thrown into the atmosphere are said to be answerable. Where electricity is the motive-power in factories and on railroads the atmosphere remains clear. By substituting electricity for steam one danger at least is thus got rid of; but electricity has dangers of its own, dangers of an acute and serious nature, and so subtle in their incidence as frequently and unexpectedly to entrap the unwary.

Electrical Accidents.

We can never tell exactly what number of deaths from acute pulmonary diseases are due to the effects of smoke and fog alone, but in countries where deaths from electrical injuries are notified the number of persons killed, also the number of persons seriously injured, can be estimated. In Great Britain the number of electrical accidents occurring in generating stations during 1911 was 74, compared with 58 for 1910, the number of deaths being 4 for each year. In factories the cases numbered 290 for 1911 and 276 for 1910, the deaths being 7 in 1911 and 5 in 1910. It is interesting to note that while in Great Britain the use of electrical energy for motive-power has risen from 30,999 horse-power in December, 1902, to 774,000 in December, 1911, there has been practically speaking no increase in the number of electrical accidents since 1907. The check in the number of accidents, according to the electrical inspector of factories, followed the issue of draft regulations by which the attention of occupiers and engineers was directed to questions of safety. The numbers given refer only to accidents in factories and generating stations; for taking the number of deaths from electricity all over the country they were 29 in 1909 and 26 in 1910, only 9 of these in 1910 occurring in generating stations and factories. As bearing upon the growing application of electricity to the industrial needs of France the increasing number of persons notified as having suffered from electrical injuries is not without significance. In 1907 there were 571 persons injured; in 1908, 773; in 1909, 778; 909 in 1910; while in 1911 the numbers rose to 1027. Taking the figures for 1911, which M. Boulin, inspecteur divisionnaire de travail of Lille, has sent me, of those injured 52 died, 12 were permanently incapacitated, and 927 were temporarily indisposed; of the remainder the results are not stated. To the above must be added other 30 persons injured in connexion with mines; of these 4 died, 1 was permanently incapacitated, and 25 temporarily so.

It is no light toll which this comparatively unknown power so recently introduced into our industries is exacting from the workers. It is one in regard to the operation of which working men must be ever on their guard, for the occasions upon which electrical currents can be used will not tend [illegible] from its [illegible] it is imp [illegible] in indus [illegible] increasingly employed. Old methods of production in chemical works are disappearing, new methods into which electricity enters are taking their place, and these are not free from danger. Because the current can be readily turned on in a factory, electricity is a force of wide application. It has been used, for example, for drilling iron plates, but the electric drill has been superseded by that worked by compressed air on account of this drill being driven more rapidly and effectively.

Causation and Nature of Electrical Accidents.

Where men have succumbed to electrical shock there may be no external marks to explain the fatality. In other instances there are burns. These when present are irregular, frequently deep, and extend down to the bone. I shall not dwell at length upon the question of what pressures of electrical currents are within the limits of safety. To measure the pressure or tension of electrical currents the term "voltage" is employed, while by "ampèrage" is meant the rate of flow. "Alternating" currents are usually regarded as more dangerous than "continuous." When death has been caused by electricity the question is generally asked, What was the voltage of the live metal at the time of the accident? The influence of ampèrage ought, however, to be considered as well as voltage. Voltages above 1000 are dangerous, but Jellinek reports a fatality where the individual had been brought into contact with only 65 volts. It is the mode of contact which is the important circumstance, also the unexpectedness of the contact, for electricians can, and do, frequently touch with their hands wires carrying currents of 5000 volts and more without experiencing any serious inconvenience. Much depends upon whether at the time of contact the skin is dry or moist, whether the workman's clothes and boots are dry or not, also whether he is standing on damp earth. The thick, hard, and dry skin of a workman's hand is less favourable to the penetration of an electrical current than the delicate or moist skin of a clerk. Although intangible, electricity is a saleable product. As a commercial commodity the dangers incidental to its generation and transmission bring it within the range of industrial hygiene. A few years ago my colleague, R. A. Gasworks Pitch and Cancer

It has long been known that persons engaged in the distillation of tar and the manufacture of grease and of briquettes, which contain coal tar oils, exhibit a peculiar swarthiness of the skin and are liable to warts and epithelioma, but it is only recently that any serious attempts, based upon clinical experience, chemical inquiry, and pathological investigation, have been made to explain the reason why, in the manufacture of patent fuel, cancer is found in men who work with gasworks pitch and not with that obtained from blast furnaces Allusion must therefore be made to the excellent work which has been done in this direction by Mr H O Ross and Dr J W Cropper, of the Lister Institute, London, also by Mr H Bayon, of Cape Colony Pitch is made from tar and tar from coal In gasworks, coal is placed in retorts and heated The gas given off is collected and distributed for illuminating and heating purposes, while the ammoniacal liquor which is formed has a commercial value The residue left in the retorts is tar This is sold to tar distillers, who by carrying the distillation further obtain phenol, creosote, naphthalene, and other valuable saleable products The residue of this distillation is known as pitch For making briquettes, small coal, anthracite dust, and pitch are used Pitch and coal dust in the proportion of 9 of pitch to 10 of coal dust are intimately ground together and thoroughly mixed The material is then taken to the pug-mills, where it is moistened by steam, and passed on to the presses where it is moulded into the forms with which we are familiar Ross and Cropper took watery extracts of the tar from which briquettes are made and tested their effects upon individual cells *in vitro* In gasworks tar they found certain chemical products which were not present in blast furnace pitch There were found in gasworks tar *auxetics*[2]—that is to say, chemical bodies liberated from cells at their death, and which when absorbed by the living cells of the tissue of an injured part stimulate these cells to unwonted activity, thereby favouring the healing of wounds, also *kinetics*, bodies which as augmentors excite amœboid movement in leucocytes and epithelial cells Acting in cooperation these two bodies stimulate cell growth, auxetics causing benign cell proliferation and kinetics cell proliferation which tends to malignancy Watery extracts of gasworks tar and of blast furnace tar were taken and injected separately into the subcutaneous tissues of animals, with the result that cell proliferation and swellings were always produced at the site of the inoculation with gasworks tar, while no such swellings akin to those caused by the gasworks product followed the injection of blast furnace tar The harmful bodies present in the gasworks tar must therefore be the auxetics and kinetics It can hardly be at any rate, the pitch dust, since no dust was present when Ross and Cropper carried on their experiments When men are making briquettes in an atmosphere laden with pitch dust and are perspiring the falling dust adheres to the moist skin, and

---

[1] Report of Committee on Compensation for Industrial Diseases, p 9

[2] The Problem of the Gasworks Pitch Industries and Cancer The Wm Howard McFadden Researches, London John Murray

I have devised an incision which appears to me to pass all the tests of a perfect abdominal incision It is small—that is to say, it is only three inches long It is a muscle splitting incision, and it crosses no nerve trunks or large blood vessels It cannot, therefore, give rise to a hernia, yet through it the whole of the pelvic ureter can be isolated and explored, and the operations be performed of uretero lithotomy, ureterectomy, and cysto ureterotresis [1]

I propose first to describe the incision and the operation for removal of stone in the lower ureter, secondly, to explain the rationale of the incision and the facts on which it is based, and finally, to add a list of the various operations which I have performed in the last two years through it

Description of Operation

The patient is anæsthetised preferably by stovaine spinal anæsthesia, and placed in the Trendelenburg position in order that the intestines may fall out of the pelvis and that light may penetrate the depths of the wound An incision is made through the skin and superficial fascia two fingers' breadth (one and a half inches) above and parallel to Poupart's ligament It is three inches long, and should extend from the edge of the rectus muscle two inches outwards and one inch inwards The centre of the incision lies vertically above the internal abdominal ring

The external oblique aponeurosis having been recognised and cleared of fat, the incision is carried through it in the direction of its fibres one inch inwards in front of the rectus muscle and two inches outwards from that muscle The external oblique aponeurosis does not usually fuse with the internal oblique aponeurosis to form the anterior sheath of the rectus muscle until at least one inch inside the edge of that muscle The cut edges of the external oblique aponeurosis are retracted so as to expose the internal oblique muscle and its sheath, the fibres of which at this point are horizontal or run slightly inwards and upwards and in the same direction as the fibres of the transversalis muscle The incision is now carried through these two muscles in the direction of their fibres for two inches outwards from the *outer edge of the rectus muscle* and *one inch inwards* through the anterior sheath of that muscle By this step the edge of the rectus muscle is clearly exposed, and the muscle belly must now be gently separated from its posterior sheath and retracted firmly inwards By this manœuvre much extra space is gained, and it is now possible to see the deep epigastric vessels as they pierce the transversalis fascia and insinuate themselves in front of the semilunar fold of Douglas to enter the rectus sheath

A finger placed just external to and above the point [illegible] sheath is [illegible] the [illegible] is so thin at this point that it is not advisable to try to divide it as a distinct layer with the knife for fear of opening into the peritoneum The transversalis fascia can then be divided with a blunt pointed bistoury outwards for the full length of the wound The finger must now be used to separate the peritoneal coat in the layer of the subperitoneal fat from the back wall of the iliac fossa and the side wall of the pelvis In the male the first structures encountered on the back wall of the fossa are the vas deferens, which should be cleared and retracted downwards and inwards, and the spermatic vessels, which should be cleared and retracted upwards and outwards In the female the ovarian vessels and round ligament correspond to these structures and should be treated in the same manner

The external iliac artery, easily recognised by its pulsation, is now cleared and followed up till the common and internal iliac arteries are likewise cleared The ureter crosses the brim of the pelvis *over the external iliac artery* and runs down the side wall of the pelvis parallel to and just in front of the internal iliac artery It lies attached to the peritoneal coat by means of a thin fascial envelope and it tends to be stripped inwards and upwards with this coat For this reason there may be some difficulty in recognising it, but by rolling the parts between the finger and thumb one can usually detect it and strip it out of its bed by means of two pairs of dissecting forceps nine inches long specially designed for this work While this is being done it may be necessary to have the parts strongly retracted with long narrow bladed retractors and to make use of a head lamp

The ureter is to be exposed at the point where it crosses the external iliac artery and cleared out of its bed for two or three inches above and below A blunt hook is passed beneath it so as to steady it and bring it nearer to the surface Two stitches of the finest chromic catgut on the finest curved needles held in a modified Halsted's needle-holder are inserted through the walls a short distance apart and parallel to one another in the long axis of the ureter These serve as retractors to steady the ureter for incision In these cases the urine is usually aseptic so that it suffices to place strips of gauze beneath the ureter to soak up the escaping urine, but if the urine is very septic it is advisable to clamp the ureter with a fine pair of intestinal clamps above the level of the proposed incision By means of a sharp tenotome a tiny longitudinal incision is made into the ureter A ureteric bougie is inserted down the cut and the position of the stone noted Special ureteric stone forceps are then gently insinuated down the tube and a few trials are generally successful in grasping the stone and lifting it out of the wound A bougie is passed into the bladder to make sure the way is clear The cut in the ureter is united by a single layer of finest chromic catgut stitches passing through all its coats This layer is covered in by another layer taking up the peri ureteric tissues and covering in the first layer

When the ureter is much dilated this procedure is easy, but in a small ureter it needs care and patience When properly performed I find that no leakage of urine occurs at all, and the wound heals by first intention and without any suppuration This is such a great gain for the patient that I cannot agree with those who recommend that the wound be left unstitched or only partially stitched It is true such a wound will heal up in time but at the cost of a lengthened convalescence and a weakened scar, and with the added risk of infection of the urine itself

The advantages are great of removing the stone in this manner The stone is brought up to a healthier portion of the ureter than that in which it lies so that the wound can heal by first intention, and there is less risk of subsequent stricture formation If at first the stone cannot be dislodged with forceps and brought up to the pelvic brim, one can often accomplish this by inserting a gloved finger into the vagina or rectum and manipulating the stone upwards from below Should this manœuvre fail, as it did in Cases 2 and 6 the ureter must be cleared out of its bed right up to the wall of the bladder In the female the uterine artery and vein have to be cut between two ligatures before one can get at the lowest portion of the ureter, and in the male the obliterated hypogastric or superior vesical artery may have to be cut across and the vas strongly retracted upwards and outwards In this way I was able to remove two stones which were almost intramural by cutting down directly on to them in the lowest part of the ureter Even at this depth stitching of the ureter can be carried out if patience be exercised

When the wound in the ureter has been dealt with the peritoneum is allowed to fall back into place a long strip cut from a rubber glove being carried from the site of the wound in the ureter up and out of the wound at the edge of the rectus Such a drain has been found by experience to draw off fluid as well as a tube, and after it has been removed leaves practically no loophole in the wound for escape of a hernia The split fibres of the internal oblique and transversalis muscles are united with chromicised catgut outside the drain The cut anterior sheath of the rectus formed by the aponeurosis of the muscles is then united in similar fashion inside the drain The split external oblique aponeurosis is united with a second layer of stitches, and finally the skin is united with silkworm gut

The patient is nursed for the next two days turned over on to the side on which the wound lies and with the head down so as to encourage drainage As a matter of fact no leakage occurred in any of my cases except Case 2 and the wound being firmly healed the patient has been allowed up on the tenth to the twelfth day and has usually left the hospital by the fourteenth to sixteenth day Urotropine is given regularly both before and after the operation so that ureteric stone are young men in the prime of life, and it is not good surgery to condemn such men to a ventral hernia if it is possible to avoid it

---

[1] In cases of acute appendicitis when the effusion is inguinal and pelvic this incision gives much better access to the parts than the usual gridiron or Battle's incision

I have devised an incision which appears to me to pass all the tests of a perfect abdominal incision It is small—that is to say, it is only three inches long It is a muscle splitting incision, and it crosses no nerve trunks or large blood vessels It cannot, therefore, give rise to a hernia, yet through it the whole of the pelvic ureter can be isolated and explored, and the operations be performed of uretero lithotomy, ureterectomy, and cysto ureterotresis [1]

I propose first to describe the incision and the operation for removal of stone in the lower ureter, secondly, to explain the rationale of the incision and the facts on which it is based, and finally, to add a list of the various operations which I have performed in the last two years through it

Description of Operation

The patient is anæsthetised preferably by stovaine spinal anæsthesia, and placed in the Trendelenburg position in order that the intestines may fall out of the pelvis and that light may penetrate the depths of the wound An incision is made through the skin and superficial fascia two fingers' breadth (one and a half inches) above and parallel to Poupart's ligament It is three inches long, and should extend from the edge of the rectus muscle two inches outwards and one inch inwards The centre of the incision lies vertically above the internal abdominal ring

The external oblique aponeurosis having been recognised and cleared of fat, the incision is carried through it in the direction of its fibres one inch inwards in front of the rectus muscle and two inches outwards from that muscle The external oblique aponeurosis does not usually fuse with the internal oblique aponeurosis to form the anterior sheath of the rectus muscle until at least one inch inside the edge of that muscle The cut edges of the external oblique aponeurosis are retracted so as to expose the internal oblique muscle and its sheath, the fibres of which at this point are horizontal or run slightly inwards and upwards and in the same direction as the fibres of the transversalis muscle The incision is now carried through these two muscles in the direction of their fibres for two inches outwards from the *outer edge of the rectus muscle* and *one inch inwards* through the anterior sheath of that muscle By this step the edge of the rectus muscle is clearly exposed, and the muscle belly must now be gently separated from its posterior sheath and retracted firmly inwards By this manœuvre much extra space is gained, and it is now possible to see the deep epigastric vessels as they pierce the transversalis fascia and insinuate themselves in front of the semilunar fold of Douglas to enter the rectus sheath

A finger placed just external to and above the point where the deep epigastric vessels enter the rectus sheath is

the

is so thin at this point that it is not advisable to try to divide it as a distinct layer with the knife for fear of opening into the peritoneum The transversalis fascia can then be divided with a blunt pointed bistoury outwards for the full length of the wound The finger must now be used to separate the peritoneal coat in the layer of the subperitoneal fat from the back wall of the iliac fossa and the side wall of the pelvis In the male the first structures encountered on the back wall of the fossa are the vas deferens, which should be cleared and retracted downwards and inwards, and the spermatic vessels, which should be cleared and retracted upwards and outwards In the female the ovarian vessels and round ligament correspond to these structures and should be treated in the same manner

The external iliac artery, easily recognised by its pulsation, is now cleared and followed up till the common and internal iliac arteries are likewise cleared The ureter crosses the brim of the pelvis *over the external iliac artery* and runs down the side wall of the pelvis parallel to and just in front of the internal iliac artery It lies attached to the peritoneal coat by means of a thin fascial envelope and it tends to be stripped inwards and upwards with this coat For this reason there may be some difficulty in recognising it, but by rolling the parts between the finger and thumb one can usually detect it and strip it out of its bed by means of two pairs of dissecting forceps nine inches long specially designed for this work While this is being done it may be necessary to have the parts strongly retracted with long narrow bladed retractors and to make use of a head lamp

The ureter is to be exposed at the point where it crosses the external iliac artery and cleared out of its bed for two or three inches above and below A blunt hook is passed beneath it so as to steady it and bring it nearer to the surface Two stitches of the finest chromic catgut on the finest curved needles held in a modified Halsted's needle-holder are inserted through the walls a short distance apart and parallel to one another in the long axis of the ureter These serve as retractors to steady the ureter for incision In these cases the urine is usually aseptic so that it suffices to place strips of gauze beneath the ureter to soak up the escaping urine, but if the urine is very septic it is advisable to clamp the ureter with a fine pair of intestinal clamps above the level of the proposed incision By means of a sharp tenotome a tiny longitudinal incision is made into the ureter A ureteric bougie is inserted down the cut and the position of the stone noted Special ureteric stone forceps are then gently insinuated down the tube and a few trials are generally successful in grasping the stone and lifting it out of the wound A bougie is passed into the bladder to make sure the way is clear The cut in the ureter is united by a single layer of finest chromic catgut stitches passing through all its coats This layer is covered in by another layer taking up the peri ureteric tissues and covering in the first layer

When the ureter is much dilated this procedure is easy, but in a small ureter it needs care and patience When properly performed I find that no leakage of urine occurs at all, and the wound heals by first intention and without any suppuration This is such a great gain for the patient that I cannot agree with those who recommend that the wound be left unstitched or only partially stitched It is true such a wound will heal up in time but at the cost of a lengthened convalescence and a weakened scar, and with the added risk of infection of the urine itself

The advantages are great of removing the stone in this manner The stone is brought up to a healthier portion of the ureter than that in which it lies so that the wound can heal by first intention, and there is less risk of subsequent stricture formation If at first the stone cannot be dislodged with forceps and brought up to the pelvic brim, one can often accomplish this by inserting a gloved finger into the vagina or rectum and manipulating the stone upwards from below Should this manœuvre fail, as it did in Cases 2 and 6 the ureter must be cleared out of its bed right up to the wall of the bladder In the female the uterine artery and vein have to be cut between two ligatures before one can get at the lowest portion of the ureter, and in the male the obliterated hypogastric or superior vesical artery may have to be cut across and the vas strongly retracted upwards and outwards In this way I was able to remove two stones which were almost intramural by cutting down directly on to them in the lowest part of the ureter Even at this depth stitching of the ureter can be carried out if patience be exercised

OBSERVATIONS ON "DIAGNOSTIC" TUBERCULIN.

BY NOEL D. BARDSWELL, M.D. EDIN.,
M.R.C.P. LOND. & EDIN., F.R.S.E.,
MEDICAL SUPERINTENDENT, KING EDWARD VII. SANATORIUM,
MIDHURST, SUSSEX.

WITH the introduction of the tuberculin test it was hoped that much of the difficulty attending the recognition of pulmonary tuberculosis in the early stages would be removed, and that in a case presenting signs and symptoms suggestive of tuberculosis, but lacking the definite proof afforded by the presence of tubercle bacilli, the application of the tuberculin test would determine the existence or non-existence of the disease. This hope has not been fulfilled. Some clinicians, however, are still of the opinion that by the use of tuberculin in such cases a definite diagnosis can be arrived at. Those who hold this view believe that a general reaction—namely, a rise of temperature, malaise, &c.—to diagnostic doses of tuberculin is sufficient proof of the existence of what may be termed "clinical tuberculosis." If, in addition, there are signs or symptoms suggestive of pulmonary tuberculosis, a positive diagnosis, in their opinion, is justified.

This view unfortunately cannot be maintained. Franz in particular has shown that a very large proportion of apparently healthy men who present no signs or symptoms whatsoever of tuberculosis give a general reaction to diagnostic doses of tuberculin, especially so if the individuals thus examined came from a district in which tuberculosis is prevalent. Such cases Lawrason Brown, of the Adirondack Sanatorium, terms "non-clinical" tuberculosis. It is probable that in such cases there has been at some time an infection with tubercle; the infection, however, has never reached the stage at which it can be diagnosed clinically, is in many cases probably obsolete, and requires nothing in the way of active treatment.

It may be said with confidence that in healthy persons the tuberculin reaction is of no clinical significance, and that in a case of ill-health a reaction to tuberculin is, in itself, no evidence that tuberculosis is the cause of the symptoms. In brief, it is generally recognised that so far as pulmonary tuberculosis is concerned tuberculin for diagnostic purposes has great limitations, since a reaction occurs as readily in cases of mere infection with tuberculosis (non-clinical tuberculosis) as in clinical tuberculosis, and in respect to clinical tuberculosis we are unable to differentiate with any certainty by the use of tuberculin between cases of active, quiescent, and arrested disease. There are, however, good grounds for holding that in the case of a patient presenting indefinite signs and symptoms the failure to react to a subcutaneous dose of 10 milligrammes is strong evidence against the existence of clinical tuberculosis, and that conversely the occurrence of a focal reaction in a suspected area in the lungs is suggestive of the existence of potentially active tubercular disease.

The above represents very briefly the state of our knowledge of the value of tuberculin as a means of diagnosis at the date of the commencement of our work on tuberculin. Since that date (October, 1911) every patient at the sanatorium in whom we have failed to find tubercle bacilli has been subjected to the subcutaneous tuberculin test. In this report I propose to record the results of these observations, and to indicate to what extent we have been influenced by them in the diagnosis and treatment of these particular cases. The number of patients thus observed up to March 31st amounted to 50.

Method of observation.—The patient (afebrile patients only are tested) is kept at physiological rest for some 48 hours before the inoculations are begun, the temperature being recorded three-hourly throughout this period and during the whole period of subsequent observations.

Dosage.—The sequence of doses used is as follows: First dose, 2/10 milligramme (0·0002 c.c.) albumose-free tuberculin; second dose, 1 milligramme (0·001 c.c.); third doses 5 milligrammes (0 005 c.c); fourth dose, 10 milligramme, (0·01 c.c.).

Site and time of inoculations.—The inoculations are made at 10 A.M., usually in the forearm.

Clinical record.—Note is made daily as to the presence of (*a*) local reaction at the seat of inoculation; (*b*) general reaction—namely, rise of temperature, malaise, &c.; also of any increase of symptoms, such as cough, sputum, &c.; and (*c*) focal reaction—namely, the appearance of, or increase in, physical signs or increase of sputum. Sputum, when available, is carefully tested for tubercle bacilli by the sedimentation method of Ellerman and Erlandson. The 50 cases now under consideration may be for convenience divided in two groups: (1) those in which there were physical signs suggesting the possibility of tuberculosis either in the lung, larynx, or pleura (37 in number); and (2) those in which no physical signs were present (13 in number). It may be assumed that all the 50 cases had something suspicious in their clinical history, symptoms, &c., inasmuch as they had been sent into the sanatorium as cases of pulmonary tuberculosis. The results of the diagnostic tests are summarised in the following table:—

—	Cases with suspicious physical signs.	Cases with no suspicious physical signs.	Total.	Per cent. of all cases.
Gave no reaction	8	3	11	22
Gave a focal reaction .	12	1	13	26
Gave a general reaction only	17	9	26	52

Indications given by the above Results.

Focal reactions.—The 13 patients who gave a focal reaction were regarded as suffering from tuberculosis in an active or

The above represents very briefly the state of our knowledge of the value of tuberculin as a means of diagnosis at the date of the commencement of our work on tuberculin. Since that date (October, 1911) every patient at the sanatorium in whom we have failed to find tubercle bacilli has been subjected to the subcutaneous tuberculin test. In this report I propose to record the results of these observations, and to indicate to what extent we have been influenced by them in the diagnosis and treatment of these particular cases. The number of patients thus observed up to March 31st amounted to 50.

Method of observation.—The patient (afebrile patients only are tested) is kept at physiological rest for some 48 hours before the inoculations are begun, the temperature being recorded three-hourly throughout this period and during the whole period of subsequent observations.

Dosage.—The sequence of doses used is as follows: First dose, 2/10 milligramme (0·0002 c.c.) albumose-free tuberculin; second dose, 1 milligramme (0·001 c.c.); third doses 5 milligrammes (0·005 c.c.); fourth dose, 10 milligramme, (0·01 c.c.).

Site and time of inoculations.—The inoculations are made at 10 A.M., usually in the forearm.

Clinical record.—Note is made daily as to the presence of (*a*) local reaction at the seat of inoculation; (*b*) general reaction—namely, rise of temperature, malaise, &c.; also of any increase of symptoms, such as cough, sputum, &c.; and (*c*) focal reaction—namely, the appearance of, or increase in, physical signs or increase of sputum. Sputum, when available, is carefully tested for tubercle bacilli by the sedimentation method of Ellerman and Erlandson. The 50 cases now under consideration may be for convenience divided in two groups: (1) those in which there were physical signs suggesting the possibility of tuberculosis either in the lung, larynx, or pleura (37 in number); and (2) those in which no physical signs were present (13 in number). It may be assumed that all the 50 cases had something suspicious in their clinical history, symptoms, &c., inasmuch as they had been sent into the sanatorium as cases of pulmonary tuberculosis. The results of the diagnostic tests are summarised in the following table:—

—	Cases with suspicious physical signs.	Cases with no suspicious physical signs.	Total.	Per cent. of all cases.
Gave no reaction	8	3	11	22
Gave a focal reaction .	12	1	13	26
Gave a general reaction only	17	9	26	52

Indications given by the above Results.

Focal reactions.—The 13 patients who gave a focal reaction were regarded as suffering from tuberculosis in an active or the work of the sanatorium A certain number of negative cases are discharged after some four weeks' observation, and a somewhat larger proportion of more suspicious cases are retained for some eight to ten weeks only, instead of the usual average of 16 weeks or more The effect of this is to increase the proportion of patients in the sanatorium who have unmistakable evidence of pulmonary tuberculosis—namely, tubercle bacilli in the sputum

Midhurst, Sussex

THE SIGNIFICANCE OF RENAL TUBE CASTS IN THE URINARY SEDIMENT[1]

BY G LESTOCK THORNTON, M A CANTAB,
M R C P LOND, M R C S ENG,

HONORARY MEDICAL OFFICER TO THE EXMOUTH DISPENSARY AND TO THE EXMOUTH COTTAGE HOSPITAL

FOR close upon ten years I have been accustomed to consider no routine examination of the urine complete without microscopical investigation of the centrifuged deposit, and realising that useful information might subsequently be derived, the results of examination have been carefully noted in a book specially tabulated for the purpose Observations of this kind taken by the man engaged in general practice have this merit, that they are not, as a rule, limited to one observation of the patient, but may often be repeated at intervals stretched over a considerable number of years There is thus at his disposal which the consultant must of necessity lack—viz, a constant means of testing the prognostic value of any given sign or symptom

With regard to the subject of this communication much has been written, and much difference of opinion expressed as to the interpretation which should be given to the presence of renal tube casts in the urine of those in whom there is no other evidence of renal disease, whilst in the case of an established nephritis no one disputes the pathological import of their presence Here, however, the teaching of the older text-books on medicine has nowadays to be modified, for Sahli, in his fourth edition of "Diagnostic Methods,"[2] says as follows "Little can be claimed for the diagnostic importance of the different varieties of casts—granular and waxy (as opposed to hyaline and epithelial) were formerly supposed to indicate a chronic process, but the idea was wrong Any and all varieties of casts may be found in every type of nephritis, and even an amyloid kidney does not produce any distinctive type of cast" I would emphasize the words *any and all varieties of casts may be found*, for so frequently one has heard it laid down that the hyaline cast is a matter of small consequence in the deposit Napoleon Boston, who has written extensively on urinary analysis is in agreement with Leube and Purdy, who state that urine containing hyaline casts either contains albumin or has recently contained it, even though in small amounts Saundby,[3] writing at a time when the centrifuge was coming more into general use, considered that the findings of that machine were such as to cause unnecessary misgivings and he sounded a warning note as to attaching too much importance to reports on urinary analyses conducted in research laboratories where the centrifuge was in routine use The article was published at a time when I had not the data by which to support or refute the statement, but during the nine years which have followed the constant examination of the deposit brings out, at any rate from my own researches two salient facts 1 The large number of cases (74 out of 134) in which, when the presence of casts was first noted the urine failed to react to the routine tests for albumin 2 Whilst the majority of these cases were examined in a condition of temporary or permanent morbidity, it is nevertheless impossible from their subsequent behaviour to dissociate the presence of casts from the particular affection in question

In support of these statements I propose to analyse briefly the 74 cases the urine of whom when first examined was found to contain casts but failed to give the reaction for albumin Of these there are—

Still living—	(a) Health fair, no albumin	29
	(b) Health indifferent (2 give tests for albumin)	22
No information		11
Died		12

Of the 29 cases in division (*a*), of those still living and whose health we can presume to be in fair although in the majority in by no means sound health, there were of—

Acute fever (typhoid 2 glandular fever, pneumonia 2)	5 cases
Cyclical vomiting with acetonæmia	1 case
Arterio-sclerosis (7 aged 70 and upwards)	10 cases
Examined for life insurance	1 case
Renal calculus	4 cases
Floating kidney	2
Furunculosis	2 ,,
Appendicitis (chronic and subsequently operated upon)	1 case
Oxaluria	1 ,,
Specific myocarditis	1 ,,
Fatty heart	1 ,,

The acute cases call for little comment, the casts appearing at an early stage of the illness and doubtless symptomatic of cloudy swelling in the kidney In the case of cyclical vomiting (child aged 4) the casts were of the hyaline varie [illegible] of the temperature and [illegible] chloride test was positi [illegible] be considered later Four cases are for convenience classified as renal calculus, but were not all verified by X ray or operation The symptoms present, however, pointed strongly, if not to the presence of an actual stone, at least to collections of crystals extensive enough to produce colic Hyaline casts have been particularly noted in a sediment rich in crystals of calcium oxalate and have disappeared *pari passu* with the latter Casts were noted in two cases of floating kidney in this series In addition the sediment in one case showed abundant epithelial cells of renal type At the operation undertaken for replacement and fixation a large hæmatoma was found beneath the true capsule Microscopical evidence of renal irritation has been my experience in a majority of these cases, and brings me to advise a belt or operation for replacement wherever I find a genuine movable kidney

The two patients suffering from boils were both men over 40 years of age, their urine contained a few hyaline casts and cylindroids Possibly these are gouty men whose kidneys are beginning to show wear and tear from elimination of an excess of waste products The case of appendicitis refers to a man aged 46 who was in a state of general ill health owing to a chronic inflammatory condition with adhesions Operation restored him to fair health but I have since had no opportunity of testing his urine The two remaining cases consulted me for cardiac conditions the first with symptoms of arrhythmia gave a history of syphilis, the second a stout middle aged lady, suffered also from "irregular gout"

Class (*b*) Health indifferent —

Valvular cardiac disease	5 cases	
Arterio-sclerosis	5 ,,	(3 over 70 years)
Glycosuria or diabetes (true)	2 ,,	
Graves's disease	1 case	
Renal colic	1 ,,	
Sciatica	1 ,,	
Old nephritis	1 ,,	
Asthma	1 ,,	
Cardiac (non valvular)	4 cases	
Gout	1 case	

In this series two of the cases occasionally show a trace of albumin

The five cases of cardiac valvular disease were patients of middle or advanced age, and the majority showed evidence of arterial degeneration No one of them showed signs of backward pressure and possibly in some of them the cast association was primarily in the kidney Of those labelled arterio sclerosis three out of five had passed their seventieth year The remaining two were aged 62 and 69 respectively, the work of the sanatorium A certain number of negative cases are discharged after some four weeks' observation, and a somewhat larger proportion of more suspicious cases are retained for some eight to ten weeks only, instead of the usual average of 16 weeks or more The effect of this is to increase the proportion of patients in the sanatorium who have unmistakable evidence of pulmonary tuberculosis—namely, tubercle bacilli in the sputum

THE SIGNIFICANCE OF RENAL TUBE CASTS IN THE URINARY SEDIMENT[1]

BY G LESTOCK THORNTON, M A CANTAB,
M R C P LOND, M R C S ENG,

HONORARY MEDICAL OFFICER TO THE EXMOUTH DISPENSARY AND TO THE EXMOUTH COTTAGE HOSPITAL

FOR close upon ten years I have been accustomed to consider no routine examination of the urine complete without microscopical investigation of the centrifuged deposit, and realising that useful information might subsequently be derived, the results of examination have been carefully noted in a book specially tabulated for the purpose Observations of this kind taken by the man engaged in general practice have this merit, that they are not, as a rule, limited to one observation of the patient, but may often be repeated at intervals stretched over a considerable number of years There is thus at his disposal which the consultant must of necessity lack—viz, a constant means of testing the prognostic value of any given sign or symptom

With regard to the subject of this communication much has been written, and much difference of opinion expressed as to the interpretation which should be given to the presence of renal tube casts in the urine of those in whom there is no other evidence of renal disease, whilst in the case of an established nephritis no one disputes the pathological import of their presence Here, however, the teaching of the older text-books on medicine has nowadays to be modified, for Sahli, in his fourth edition of "Diagnostic Methods,"[2] says as follows "Little can be claimed for the diagnostic importance of the different varieties of casts—granular and waxy (as opposed to hyaline and epithelial) were formerly supposed to indicate a chronic process, but the idea was wrong Any and all varieties of casts may be found in every type of nephritis, and even an amyloid kidney does not produce any distinctive type of cast" I would emphasize the words *any and all varieties of casts may be found*, for so frequently one has heard it laid down that the hyaline cast is a matter of small consequence in the deposit Napoleon Boston, who has written extensively on urinary analysis is in agreement with Leube and Purdy, who state that urine containing hyaline casts either contains albumin or has recently contained it, even though in small amounts Saundby,[3] writing at a time when the centrifuge was coming more into general use, considered that the findings of that machine were such as to cause unnecessary misgivings and he sounded a warning note as to attaching too much importance to reports on urinary analyses conducted in research laboratories where the centrifuge was in routine use The article was published at a time when I had not the data by which to support or refute the statement, but during the nine years which have followed the constant examination of the deposit brings out, at any rate from my own researches two salient facts 1 The large number of cases (74 out of 134) in which, when the presence of casts was first noted the urine failed to react to the routine tests for albumin 2 Whilst the majority of these cases were examined in a condition of temporary or permanent morbidity, it is nevertheless impossible from their subsequent behaviour to dissociate the presence of casts from the particular affection in question

In support of these statements I propose to analyse briefly the 74 cases the urine of whom when first examined was found to contain casts but failed to give the reaction for albumin Of these there are—

Still living—	(a) Health fair, no albumin	29
	(b) Health indifferent (2 give tests for albumin)	22
No information		11
Died		12

Of the 29 cases in division (*a*), of those still living and whose health we can presume to be in fair although in the majority in by no means sound health, there were of—

Acute fever (typhoid 2 glandular fever, pneumonia 2)	5 cases
Cyclical vomiting with acetonæmia	1 case
Arterio-sclerosis (7 aged 70 and upwards)	10 cases
Examined for life insurance	1 case
Renal calculus	4 cases
Floating kidney	2
Furunculosis	2 ,,
Appendicitis (chronic and subsequently operated upon)	1 case
Oxaluria	1 ,
Specific myocarditis	1 ,,
Fatty heart	1 ,

The acute cases call for little comment, the casts appearing at an early stage of the illness and doubtless symptomatic of cloudy swelling in the kidney In the case of cyclical vomiting (child aged 4) the casts were of the hyaline varie [illegible] of the temperature and [illegible] chloride test was positi [illegible] be considered later Four cases are for convenience classified as renal calculus, but were not all verified by X ray or operation The symptoms present, however, pointed strongly, if not to the presence of an actual stone, at least to collections of crystals extensive enough to produce colic Hyaline casts have been particularly noted in a sediment rich in crystals of calcium oxalate and have disappeared *pari passu* with the latter Casts were noted in two cases of floating kidney in this series In addition the sediment in one case showed abundant epithelial cells of renal type At the operation undertaken for replacement and fixation a large hæmatoma was found beneath the true capsule Microscopical evidence of renal irritation has been my experience in a majority of these cases, and brings me to advise a belt or operation for replacement wherever I find a genuine movable kidney

The two patients suffering from boils were both men over 40 years of age, their urine contained a few hyaline casts and cylindroids Possibly these are gouty men whose kidneys are beginning to show wear and tear from elimination of an excess of waste products The case of appendicitis refers to a man aged 46 who was in a state of general ill health owing to a chronic inflammatory condition with adhesions Operation restored him to fair health but I have since had no opportunity of testing his urine The two remaining cases consulted me for cardiac conditions the first with symptoms of arrhythmia gave a history of syphilis, the second a stout middle aged lady, suffered also from "irregular gout"

Class (*b*) Health indifferent —

Valvular cardiac disease	5 cases	
Arterio-sclerosis	5 ,	(3 over 70 years)
Glycosuria or diabetes (true)	2 ,	
Graves's disease	1 case	
Renal colic	1 ,	
Sciatica	1 ,	
Old nephritis	1 ,,	
Asthma	1 ,,	
Cardiac (non valvular)	4 cases	
Gout	1 case	

In this series two of the cases occasionally show a trace of albumin

The five cases of cardiac valvular disease were patients of middle or advanced age, and the majority showed evidence of arterial degeneration No one of them showed signs of backward pressure and possibly in some of them the cast association was primarily in the kidney Of those labelled arterio sclerosis three out of five had passed their seventieth year The remaining two were aged 62 and 69 respectively, who took up bicycling at the age of 50. Some seven years ago, when aged 60, he consulted me about his urine, as diabetes was a family disease. I could detect no sugar, but found the specific gravity high and the deposit to contain [illegible] The heart sounds were normal. [illegible] but this time for a slight fainting [illegible] church; it was at the beginning of service, and he had almost run the distance of 300 yards from his house to the church. There was now a loud systolic murmur replacing the first sound at the apex, which was located in the mid-clavicular line. There was no œdema and no albumin, but the urine showed the presence of plentiful casts. His life has now been remodelled in many respects, and his condition improved in consequence.

[1] A paper read before the Devon and Exeter Medico-Chirurgical Society on April 11th 1913

[2] Translated by Kinnicutt and Potter

[3] Medical Annual 1904

The term "de senectute" is now proscribed by the registrar-general, and the obituary list of any morning paper points at any rate to a need for correction of the Psalmist's figures for present-day needs. A man is as old as his arteries, and old age is in the majority of cases but an expression of the extreme limit of what was dignified in earlier years by the title arterio-sclerosis. I have frequent opportunity for the investigation of the urine of those of advanced years (+75), and casts, hyaline, or granular and hyaline, are as frequently noted. That they are present probably in the majority of those aged 70 and upwards is no reason why they should be regarded as non-pathological. They are, on the contrary, evidence of renal changes consequent upon backward pres- [illegible] re content with the [illegible] are forced, in the [illegible] pting the processes [illegible] so, however, with [illegible] of casts should be regarded as evidence of undue wear and tear, and as a distinct, if the only, warning—"the cloud no bigger than a man's hand"—that announces the coming storm.

Including the cases with albuminuria, 12 patients with diabetes or glycosuria appear in my notebook. Of these, no less than 11 showed casts in the urine. In respect of treatment it is extremely difficult to protect the kidney. In the composite forms it is often quite impossible to keep the output of sugar below 2 or 3 per cent, and the kidney must eventually suffer. In the alimentary form Pavy[6] tells us that the casts and albumin will often disappear when the diet is restricted. At any rate, casts should be sought for if only as an element in the prognosis.

With regard to the varieties of casts found in the urine, I think that much confusion exists owing to the fact that no strict line of demarcation exists between them if we except the epithelial and blood forms. Some would define as hyaline the cast that another would classify as finely granular, and the personal equation enters here, as it so often does in the estimation of leucocytes in blood examinations. The exact distinction between fatty and granular is hard to define, and lardaceous is a term of the past. Granting the distinctions, we are still ignorant of why some casts are granular, some hyaline, and others fatty. My own observations have brought me to think that the hyaline cast when found unaccompanied is an indicator that the kidney is still active as an organ of filtration, whereas some stagnation is necessary for the appearance noted in the granular and fatty forms. The actual composition of the granules seems also to be a subject upon which there has been no settled agreement.

In conclusion, I should like to advocate the more general use of the centrifuge. Apart from cast-finding, many a diagnosis can be clinched in five minutes in comparison with 24 hours with the conical glass, to say nothing of the urine being stale and unreliable with the latter alternative. Only a few weeks ago I found much difficulty in the diagnosis of a case [illegible] rectus, did equally [illegible] centrifuge and mic [illegible] few blood cells and hyaline casts and plentiful crystals of oxalate of calcium being found on the slide. Macroscopically the urine could have passed muster on the first examination. [illegible] microscopical investigation [illegible] be a *sine quâ non*, and the [illegible] should be found.

Once more I would like to emphasise the importance of searching the urinary sediment of middle-aged people with a raised blood pressure for the presence of casts, which, if present, may be the only warning that the machinery will give way unless the load is speedily lightened. Falstaff is generally represented to us as a man who might have been full to the brim with waste products and of high arterial tension, yet the page answers thus to his query, "What says the doctor to my water?" "He said, Sir, the water itself was a good healthy water: but, for the party that owed it, he [illegible] doctor [illegible] rifuge [illegible] been somewhat modified in respect of that sample.

THE COLLOIDS OF IRON.

By LYN DIMOND, M.B. VICT.,

LATE PATHOLOGIST AND BACTERIOLOGIST, ROYAL SOUTHERN HOSPITAL, LIVERPOOL.

THAT iron in one or other of its colloid forms will ultimately play an important part in the therapy of anæmia and allied conditions, more especially by administration by the hypodermic route, prompts me to give a short account of some experiences of the therapeutic employment of certain colloid solutions or sols of this element.

Those who have used the liquor ferri dialysatus of the old Pharmacopœia can have but little doubt as to its very great value in the treatment of chlorosis and certain secondary anæmias, more especially those cases that were unable to tolerate other preparations of iron. The liquor ferri dialysatus prepared according to the Pharmacopœial directions consists of a colloid peroxide of iron, and is in many ways a most remarkable preparation. The disperse phase of this sol is electro-positive, its particles or meres passing to the kathode when a current of electricity is passed through it; [illegible] in consequence, at once takes place when [illegible] is negative are added, such as [illegible] silicic acid, and the electro-negative colloids of the blood serum. This precipitation, or rather gelatinisation, is to a certain extent reversible, and the addition of water will redissolve the coagulum, in contradistinction to the coagulum of colloid silicic acid, in which case no amount of water will bring about re-solution.

The search for an organic protective colloid which would prevent or minimise this tendency of the sol to gelatinise failed to yield this happy result, due, no doubt, to the fact that the disperse phase of the majority of the organic colloids tried possessed an opposite electric sign to that of the positively charged particles of the peroxide sol. Consequently it was hardly to be expected that the colloids which efficiently protected the metallic sols of same electric sign would do so in the case of a colloid of opposite sign. Glycerine, however, in the small amount of 1 per cent., undoubtedly preserves this preparation and prevents the formation of a bulky jelly in the presence of the electrolytes and oppositely charged colloids of the blood serum.

My first attempts to employ this colloid hypodermically were with sols made in one of the following two ways. In the first a 30 per cent. solution of ferric chloride is added to a measured amount of boiling distilled water, the sol which forms being freed from free hydrochloric acid by dialysis. In the second the hydrate of iron precipitated from ferric chloride by ammonia is redissolved in hot chloride of iron solution and the free acid removed by dialysis for ten days in running water. The sol so obtained is standardised by means of a colorimeter, so as to be equal to one-quarter the strength of the liquor ferri dialysatus of the old Pharmacopœia. This peroxide sol, rendered somewhat more stable by the addition of 1 per cent. of pure glycerine, can be employed hypodermically without untoward result of any sort.

After using it a considerable number of times in different cases of deficient blood conditions, none of the patients so treated complained that the injection was in any way accompanied by pain, at any rate, no more painful than ordinary hypodermic injections of morphine or strychnine, which for different reasons several of the patients undergoing this treatment required. The slight swelling which comes on who took up bicycling at the age of 50. Some seven years ago, when aged 60, he consulted me about his urine, as diabetes was a family disease. I could detect no sugar, but found the specific gravity high and the deposit to contain [illegible] The *heart sounds were normal.* [illegible] but this time for a slight fainting [illegible] church; it was at the beginning of service, and he had almost run the distance of 300 yards from his house to the church. NOTES ON TWO UNUSUAL CASES OF INFANTILE SCURVY.

BY ERIC PRITCHARD, M.A., M.D. OXON., M.R.C.P. LOND.,
SENIOR ASSISTANT PHYSICIAN TO THE QUEEN'S HOSPITAL FOR CHILDREN.

ON March 27th, 1912, I saw, in consultation with Dr. E. C. Gimson, of Witham, Essex, a female baby aged 9 months. The infant had made satisfactory progress until 14 days previously, when a slight feverish attack supervened, which at the time was ascribed to the cutting of a tooth. The condition, however, did not improve, and the child became obviously ill, with a running temperature ranging beween 100° and 101° F., quick breathing, and a rapid pulse. The striking feature of the case, however, was the development of a generalised œdema, which gave the infant a very puffy and bloated appearance; in the words of the mother, the child "grew larger and larger every day." This condition naturally gave rise to a suspicion of some involvement of the kidney, but the urine, which had been collected and examined before my arrival, showed no trace of albumin or other abnormality.

When I saw the infant on March 27th she was evidently in a serious condition; the respiration rate was about 90, the temperature 101°, and the whole body enormously swollen and œdematous in appearance. There was little or no tenderness of the limbs, only slight sponginess of the gums, and no indications of hæmorrhage from the kidneys, bowels, or other organ in the body, and beyond rapidity of action no abnormality could be detected in the lungs or heart. The reflexes were slightly sluggish, and the infant lay in a distinctly lethargic condition. From a review of the method of feeding I felt convinced that this was an abnormal case of scorbutus, and so subsequent events clearly proved, for although on the following day the infant had hæmorrhage from the bowel, subsidence of the œdema and recovery from the other symptoms took place almost miraculously under antiscorbutic treatment.

The interest of this case lies in the extensive development of the œdema from which no part of the body seemed exempt. When I saw her the infant had a pallid, waxy appearance, which I was told was in striking contrast to the healthy, pink colour of the skin of some days before. Another peculiarity of the œdema was that, although it looked as if it would easily pit on pressure, it was practically impossible to obtain a permanent indentation with the fingers, no matter how deeply they were inserted into the skin. I have several times noticed this same characteristic with œdema in scurvy, but I have never seen so extensive a case before, nor one in which the absence of pitting was so marked.

The second case was referred to me by Mr. R. G. Dainty, resident medical officer at the St. Marylebone General Dispensary. The history of the case was as follows. On March 30th of this year an infant, aged 10 months, fell from a mail cart on to a mat on the floor; it did not appear at the time to be seriously injured, but the same evening a swelling *gradually appeared on the side of the head on which it had* fallen. On the following day the infant was examined by Mr. Dainty, who at the time did not detect any serious symptoms beyond the swelling on the head which had now attained to considerable proportions. When, however, a few days later the swelling had increased rather than decreased in size, and the child seemed lethargic and disinclined to move, Mr. Dainty decided to ask my opinion as to whether I thought that the hæmatoma of the scalp could in any way be associated with intracranial pressure.

On examination I could find no evidence of cerebral pressure, but on inquiry I discovered that the infant had not been well for some days before the accident. The child had been lethargic, disinclined to move, had had no appetite, and seemed generally indisposed. The method of feeding again was not without its significance. I found that there was general tenderness over all the limbs, and evidently strong aversion to being moved or otherwise disturbed. The gums were spongy and of a purple colour. I therefore prescribed an antiscorbutic diet of orange-juice, raw meat-juice, egg water, and milk, and strongly advised against aspiration or other interference with the hæmatoma of the scalp, which by the time of my examination had assumed an enormous size. The general condition of the infant rapidly improved under this treatment, and at the end of 10 days it had practically returned to normal health and showed an increase in weight of over 18 oz.

Harley street, W.

NOTE OF A CASE OF

URETHRAL CALCULUS OF UNUSUALLY LARGE SIZE.

BY E. A. WALKER, M.B. EDIN., F.R.C.S. EDIN.,
CAPTAIN, I.M.S., CIVIL SURGEON, MEIKTILA, BURMA.

A *BURMESE man, aged 28, was admitted to the Meiktila* Civil Hospital on Feb 23rd, 1913, by my assistant surgeon, complaining of inability to pass urine freely; duration of illness three months.

The patient was in bad condition, very thin, covered with itch, and his clothes were soaked with decomposed urine. On examination the bladder was found to be dilated to about 5 inches above the pubes. On passing a metal catheter, this was arrested about the membranous part of the urethra, and a distinct grating sensation was felt as if the instrument had impinged on a stone. This was confirmed by a rectal examination, when a densely hard lump was felt at the anterior part of the prostate and running forward into the perineum. Its exact boundaries could not be made out, but it was realised that the calculus was of large size. The patient's history threw little light on the condition. He insisted that the difficulty in micturition had only been noticed for the last three months, and that before that he was perfectly well except for an attack of gonorrhœa. There was no history of renal colic, nor of any previous passage of calculi by the urethra

Owing to my absence in the district the operation was not performed until March 2nd The patient was anæsthetised with chloroform and placed in the lithotomy position. A median perineal incision 2 inches long was made from a point ½ inch in front of the anus. This had subsequently to be enlarged anteriorly almost to the base of the scrotum. The incision was carried down to a staff in the urethra, which was opened just behi [illegible] and the calculus immediately [illegible] properly the urethra had to [illegible] about 3 inches, dividing parts of the prostatic, membranous, and spongy portions. There was fairly free hæmorrhage from the cut corpus spongiosum at this stage. The calculus was now found to be lying free in a smooth-[illegible] formed by the dilated urethra. It was [illegible]ioniacal urine and a small [illegible] of its removal now became acute; unfortunately, we had no lithotrite available, as its use had not been anticipated, and the nearest instrument is kept at Myingyan, the next district headquarters. However, by getting one finger round the calculus and manœuvring it so that its smallest diameter was at right angles to the wound, and by the expenditure of a considerable amount of force, it was eventually delivered Its removal caused some bruising and tearing of tissue and free hæmorrhage, and the escape of a large quantity of urine Hæmorrhage was arrested by ligatures and extensive plugging

NOTES ON TWO UNUSUAL CASES OF INFANTILE SCURVY.

BY ERIC PRITCHARD, M.A., M.D. OXON., M.R.C.P. LOND.,
SENIOR ASSISTANT PHYSICIAN TO THE QUEEN'S HOSPITAL FOR CHILDREN.

BY E. A. WALKER, M.B. EDIN., F.R.C.S. EDIN.,
CAPTAIN, I.M.S., CIVIL SURGEON, MEIKTILA, BURMA.

A BURMESE *man, aged 28, was admitted to the* Meiktila Civil Hospital on Feb 23rd, 1913, by my assistant surgeon, complaining of inability to pass urine freely; duration of illness three months.

The patient was in bad condition, very thin, covered with itch, and his clothes were soaked with decomposed urine. On examination the bladder was found to be dilated to about 5 inches above the pubes. On passing a metal catheter, this was arrested about the membranous part of the urethra, and a distinct grating sensation was felt as if the instrument had impinged on a stone. This was confirmed by a rectal examination, when a densely hard lump was felt at the anterior part of the prostate and running forward into the perineum. Its exact boundaries could not be made out, but it was realised that the calculus was of large size. The patient's history threw little light on the condition. He insisted that the difficulty in micturition had only been noticed for the last three months, and that before that he was perfectly well except for an attack of gonorrhœa. There was no history of renal colic, nor of any previous passage of calculi by the urethra

Owing to my absence in the district the operation was not performed until March 2nd The patient was anæsthetised with chloroform and placed in the lithotomy position. A median perineal incision 2 inches long was made from a point ½ inch in front of the anus. This had subsequently to be enlarged anteriorly almost to the base of the scrotum. The incision was carried down to a staff in the urethra, which was opened just behi[illegible] and the calculus immediately [illegible] properly the urethra had to [illegible] about 3 inches, dividing parts of the prostatic, membranous, and spongy portions. There was fairly free hæmorrhage from the cut corpus spongiosum at this stage. The calculus was now found to be lying free in a smooth-[illegible] by the dilated urethra. It was [illegible] ioniacal urine and a small [illegible] of its removal *now became* acute; unfortunately, we had no lithotrite available, as its use had not been anticipated, and the nearest instrument is kept at Myingyan, the next district headquarters. However, by getting one finger round the calculus and manœuvring it so that its smallest diameter was at right angles to the wound, and by the expenditure of a considerable amount of force, it was eventually delivered Its removal caused some bruising and tearing of tissue and free hæmorrhage, and the escape of a large quantity of urine Hæmorrhage was arrested by ligatures and extensive plugging

Chylous and Chyliform Effusions

A MEETING of this section was held on May 27th, Dr FREDERICK TAYLOR, the President, being in the chair

Dr H A LEDIARD described cases of Chyliform Effusion into the Peritoneum One of these occurred in a youth, *aged 18 years, who had had tuberculous disease within the* abdomen for 12 years and ascites for six years When exploratory incision was made a large amount of pure white milk fluid was evacuated At the necropsy, made by Professor J M Beattie, of Liverpool, there was a fibrous mass of glands obliterating the receptaculum chyli and the mesenteric glands showed dilatation of their efferent channels Chyle had transuded into the peritoneal cavity Tubercle was found almost everywhere in the system—spleen, liver, kidney, membranes of the brain, lungs, mesenteric glands, and intestinal peritoneum The next case was that of a girl, aged 16 years, the subject of lymphadenoma, who had undergone two operations—one for removal of glands in the left neck and the other for removal of glands in the left axilla Sudden abdominal pain and vomiting led to puncture of the peritoneum and the finding of a chyliform fluid It was assumed that pressure of glands in the neck had blocked the thoracic duct there being *enlarged glands in the neck on* both sides Dr Lediard mentioned another case of a female with advanced mitral and liver affection with ascites, which when tapped showed a chyliform fluid

Mr MACKENZIE WALLIS spoke of the points of distinction between chylous and pseudo chylous effusions, which might be summarised briefly as follows —

Chylous Ascites	*Pseudo-chylous Ascites*
1 Tends to accumulate very rapidly and in consequence large volumes are removed at paracentesis	1 Collects more slowly the volume of the fluid varying with the exciting pathological condition
2 Generally yellowish white in colour and less perfectly emulsified	2 In colour a pure milky white solution in the form of an almost perfect emulsion
3 Degree of opalescence more or less constant at successive tappings	3 *The opacity generally in*creases or diminishes at successive tappings
4 Possesses an odour corresponding to the odour of the food ingested	4 Odourless
5 Microscopically the fluid contains fine fat globules but very few cellular elements	[illegible] and often contain fat sometimes very scanty
6 Generally shows a distinct creamy layer on standing	6 A cream may or may not *form but does not affect the* opalescence a sediment frequently settles out
7 Specific gravity generally exceeds 1012	7 Specific gravity less than 1012
8 Depression of freezing point about 0 51° C and approximating that for chyle	8 Depression of freezing point ranges from 0 56° to 0 61° and thus corresponds to the figures for blood serum
9 Total solids vary considerably but usually greater than 4 per cent	9 Total solids rarely exceed 2 per cent
10 The total protein content generally exceeds 3 grammes per cent, and of this the serum albumin is the largest fraction, globulin occurring only in traces	10 The protein constituents vary between 1 and 3 grammes per cent, and of these the serum globulin occurs in appreciable quantities
11 Mucinoid substances absent	11 Mucinoid sometimes present
12 [illegible] food	12 The fat content is generally low and may be present in traces only In its melting point and chemical composition it proves to be pathological fat
13 [illegible]	13 The most characteristic lipine is lecithin though cholo [illegible]
[illegible]	[illegible] resist putrefaction
15 The salts and the organic substances present approximate to the values found for chyle obtained from the thoracic duct	15 The salts and organic materials correspond closely to lymph and serous fluids

Mr Wallis gave a scheme of procedure necessary to establish whether a fluid obtained from a patient was chylous or pseudo chylous in nature, or a mixed form The specific gravity, total solids, and ash should be ascertained as soon as possible after withdrawal. The fat and lipines might be removed in several ways, either by ether extraction of the fluid or extraction with hot alcohol The ordinary method of extraction with ether had, however, many disadvantages, chief amongst them being the fact that the proteins present were partially precipitated, and in pseudo chylous effusions the lecithin as well By precipitating the proteins with boiling alcohol and repeated extraction of the residue with *alcohol the lipines and fat were entirely removed* The alcohol residue could then be extracted with ether *and the fat and other ether soluble substances isolated* The nature of the fat, its melting point, saponification figure, and ether figure should be observed, as by this means a distinction between normal human fat and pathological fat could be made The presence of lecithin and its condition in the fluid were also of importance, and this could be established either by precipitation methods or by dialysis The presence or absence of sugar appeared to be of little value for diagnostic purposes, since it might or might not be present in either of the two types of effusion The other organic constituents, such as urea, uric acid, bile components, occur in very small quantities, and are apparently of no special significance The presence of such inorganic salts as chlorides and phosphates might be ascertained by an analysis of the ash Finally, the depression of the freezing point should be determined as this gives an indication of the quantity and distribution of the inorganic salts present

SECTION OF THE HISTORY OF MEDICINE

The Ancient System of Hindu Medicine —The Hospital and Chapel of Saint Mary Roncevall at Charing Cross —Dr Thomas Dover —Exhibition of Objects of Historical Interest

A MEETING of this section was held on May 28th, Sir WILLIAM OSLER the President, being in the chair

The meeting was declared to be the annual meeting, and it was decided unanimously that as the section was less than a year old no change should be made in the list of officers and council upon the present occasion

The PRESIDENT announced that at least three lectures would be given during the ensuing year upon subjects connected with the history of medicine The lectures would be public, and the names of the lecturers, as well as of the subjects chosen, would shortly be made known He further stated that the section was about to issue a fasciculus containing the various known portraits of William Harvey The fasciculus would be sold to those members of the section who wished to possess it at a price calculated to cover the expense of production It would probably contain 16 or 17 portraits

Dr D J A CHOWRY MUTHU (Wells) read a paper on the Ancient System of Hindu Medicine The Hindu civilisation was he said the most ancient in the world The astronomical allusions in the hymns of the Rig Veda (the oldest literature in the world) went back from 6000 to 4000 B C The records found by Megasthenes at Polybhotra, the residence of Chandragupta (312 B C), furnished the names and the duration of reign of 153 kings from Dionysius (an Indian king) to Chandragupta, together amounting to 6451 years India sent out colonies [illegible] and civilisation to ancient Egypt [illegible] later to Mexico Peru, Java and the Archipelago She perfected [illegible] (Sanscrit) which became the mother of all European languages The art of writing had been in use in India since the Vedic times Count Bjornstjerna had stated that the Hindus possessed 'written books of religion' before 2800 B C, or 800 years before Abraham The Hindus cultivated every branch of science and philosophy They invented geometry, trigonometry, algebra, the numerical figures (1 to 9) of arithmetic, the decimal system and the game of chess now used all over the world India was the birthplace of fables of animals and tales which are now the nursery stories of England America and the rest of the world The "Thousand and One Nights" was of Hindu origin from Sanscrit (Vrihat Katha) so also was the book of 'Sindebad" India's

belonged to Norfolk, at any rate we can trace it no further back. His grandfather was an attorney who settled to practise in the small Cotswold town of Barton-on-the-Heath in the county of Warwickshire. This is a queer corner of England where Warwickshire, Worcestershire, Gloucestershire, and Oxfordshire seem to jostle each other for possession of some of the beauty spots of the land. Robert Dover's name has come down to us as a peace-loving lawyer "who never try'd but two causes, always made up the difference." He lived in the reign of James I., and being a man of hospitable and cheerful disposition he instituted, in imitation of the Olympic games of Greece, an annual meeting for manly sports and exercises, which became known as the Cotswold Games, on a hill near Campden that bears now the name of Dover's Hill. These games were held yearly until in 1851 they were stopped by Act of Parliament, having degenerated into a Whitsun gathering of the lowest scum of the population living between Birmingham and Oxford. An interesting book of encomiastic poems was published in 1636, in which many poets of various attainments, amongst them Ben Jonson and Michael Drayton, made verses in honour of Robert Dover and his games. The title of the collection is "Annalia Dubrensia," and Michael Drayton's contribution stands first, headed, "To my noble friend, Mr. Robert Dover on his brave annuall assemblies upon C [illegible]
C [illegible]
C [illegible]
whom the elder boy, Robert, died in infancy. John, his second son, was born in 1614, and is said to have been baptised at Sainsbury. He was one of Prince Rupert's captains, and married Elizabeth Vade, of Barton, by whom he had five daughters and three sons. Of the sons two lived to adult life. John, the elder, entered Magdalen Hall, Oxford, and resided for four years (1661–65), but did not take a degree. He then studied the law at Gray's Inn, and made some slight reputation as a dramatist. Ultimately he took orders in the Church, and in 1688 became Rector of Drayton, Oxon, where he died at the age of 82 in 1725. Thomas, the younger surviving son of Captain John Dover, matriculated at Magdalen Hall, Oxford, in 1680 at the age of 16, and seems to have studied medicine there until 1686, when he migrated to Gonville and Caius College, Cambridge. The register of admissions shows his entry in 1686: "Thomas Dover from St. Mary Hall Oxford, where he resided six years, admitted pensioner to the Scholars' table. Surety: Mr. Lightwine. Matriculated at Magdalen Hall, December 1, 1680. Age 16. Son of John Dover of Barton-on-the-heath, Warwicks., gent B A. Oxford 1684, M.B. Cambridge 1687." Shortly after this time Thomas Dover became the resident pupil of Sydenham in London. He has left a description of his treatment on this occasion. "Whilst I lived with Dr. Sydenham, I had myself the Small Pox, and fell ill on the Twelfth-Day. In the Beginning I lost Twenty-two Ounces of Blood: He gave me a vomit; but I find by experience Purging much better. I went abroad, by his Direction till I was blind, and then took to my Bed. I had no Fire allowed in my Room; my Windows were constantly open, My Bed-Clothes were order'd to be laid no higher than my Waist. He made me take Twelve Bottles of Small-Beer, acidulated with Spirit of Vitriol every Twenty-four Hours." Presently Dover settled in Bristol and achieved honourable distinction as the first medical man who gratuitously offered his services on behalf of the poor under the care of the guardians of that city. This was in 1696, during an epidemic of spotted fever of which he wrote later: "About Fifty Years since, this Fever raged so much in Bristol, so that I visited from Twenty-five to thirty Patients, a Day for a considerable Time, besides their poor children taken into their Workhouse, where I engaged myself, for the Encouragement of so good and charitable an Undertaking, to find them Physick, and give them Advice at my own Expence and Trouble, for the two first years. All these poor Children in general had this Fever, yet no more than one died out of the whole Number, which was near two hundred." The hospital where Dover worked is a well-known landmark in Bristol, called St. Peter's Hospital, and now used as the offices of the guardians. In 1708 he sailed on his famous voyage round the world, two accounts of which were published in 1712. Of these the better known is by Woodes-Rogers, captain of the *Duke* and commander of the expedition, while the less known but better written description is by Captain Edward Cooke, second in command of the *Dutchess*. Callander, in his "*Voyages to the Terra Australis*" (London, 1768), speaks in terms of the highest praise of this expedition as one of the best organised and equipped expeditions that ever left England. The enterprise was undertaken by a group of wealthy Bristol citizens, several of whom were members of the Society of Merchant Venturers in Bristol. Three of the owners were sooner or later Mayors of Bristol, two were sheriffs, and one (John Romsey) town clerk. The ships are said to have been the property of Joseph Harford, whose family is still one of the most notable in Bristol. The *Duke* and *Dutchess* were legally commissioned by His Royal Highness Prince George of Denmark, then Lord High Admiral of Great Britain, Ireland, &c., "to cruise on the Coasts of *Peru* and *Mexico*, in the *South Seas*, against her Majesty's enemies the *French* and *Spaniards*." The expedition consisted of six ships, all armed, under the *Hastings* man of war (42 guns); the *Duke* carried 30 guns and the *Dutchess* 26 guns. The voyage was distinguished by three achievements: the taking of the town of Guayaquil, the capture of the lesser Manila treasure-ship, and the relief of Alexander Selkirk from his voluntary exile on the island of Juan Fernandez. Dr. Dover was appointed after a dispute with Woodes-Rogers to the nominal command of the *Manila* prize, renamed [illegible]
account of this [illegible]
of Dover—"that [illegible]
prize that Captain Dover command her, because his temper is so violent, that capable men cannot well act under him and himself is uncapable." Cooke, however, took Dover's part, and with a majority of the officers protested that he should be appointed to the command. Ultimately he was appointed the nominal commander with two other captains to navigate the ship and the proviso "that the said Capt. Tho. Dover, shall not molest, hinder or contradict them in their business." In Cooke's opinion Woodes-Rogers was no easy man to get on with, while Callander describes Dover as having the reputation of being "of rough temper and could not easily agree with people about him. But his untoward disposition had one good effect, which was this; that it hindered his making any party [illegible] pite of all differences [illegible] with rich booty in [illegible] emain in Bristol Cathedral as the thankoffering of John Romsey, the town clerk, for the success of the venture. After his return Dover practised medicine in Bristol, Gloucestershire, and London, at various times, and made no little stir by his advocacy of the use of crude mercury in the treatment of many diseases. It is suggested that it was Dover who introduced Selkirk to Daniel Defoe and persuaded the former to [illegible] "Robinson Crusoe."
[illegible] in the Star Tavern
i[illegible] ting is wanting, but certainly Selkirk conceived a grievance against Defoe for stealing his story and swelling it into the great romance, "Robinson Crusoe" Mr. Colyer-Ferguson has inquired industriously into the family connexions of Dr. Dover and has brought to ligh [illegible]
soon after leaving [illegible]
unsolved. Her Ch [illegible]
buried at Barton-on-the-Heath, April 27th, 1727. Their family consisted of four daughters, of whom the first were twins, baptised at Barton in 1688, and died young. A third daughter, Elizabeth, married John Opie and died without issue. The marriage settlement of this daughter is now in Mr. Colyer-Ferguson's possession, and is interesting from the fact that it bears the signature of Dr. Thomas Dover. The fourth daughter, Sibilla, married John Hunt and left many descendants, of whom Mr. Colyer-Ferguson claims to be one. History and tradition have played strange pranks with Dover's biography, and much confusion has existed between Dr. Thomas Dover and his grandfather Robert Dover. Thomas Dover has been credited by several of the county historians of Gloucestershire with being the founder of the [illegible] by
Cotswold games, whil [illegible] er's

After his return Dover practised medicine in Bristol, Gloucestershire, and London, at various times, and made no little stir by his advocacy of the use of crude mercury in the treatment of many diseases. It is suggested that it was Dover who introduced Selkirk to Daniel Defoe and persuaded the former to [illegible] "Robinson Crusoe." [illegible] in the Star Tavern [illegible]ting is wanting, but i[illegible] certainly Selkirk conceived a grievance against Defoe for stealing his story and swelling it into the great romance, "Robinson Crusoe" Mr. Colyer-Ferguson has inquired industriously into the family connexions of Dr. Dover and has brought to ligh[illegible] soon after leaving [illegible] unsolved. Her Ch[illegible] buried at Barton-on-the-Heath, April 27th, 1727. Their family consisted of four daughters, of whom the first were twins, baptised at Barton in 1688, and died young. A third daughter, Elizabeth, married John Opie and died without issue. The marriage settlement of this daughter is now in Mr. Colyer-Ferguson's possession, and is interesting from the fact that it bears the signature of Dr. Thomas Dover. The fourth daughter, Sibilla, married John Hunt and left many descendants, of whom Mr. Colyer-Ferguson claims to be one. History and tradition have played strange pranks with Dover's biography, and much confusion has existed between Dr. Thomas Dover and his grandfather Robert Dover. Thomas Dover has been credited by several of the county historians of Gloucestershire with being the founder of the Cotswold games, whil[illegible] by [illegible] the same authorities [illegible] er's tomb at Stanway in [illegible] as follows. Robert Dov[illegible] was [illegible] buried at Barton on [illegible] to this effect in the Barton register, but I can find no tablet to were thought to be due to appendicitis, and the patient was sent to infirmary for operation An easily palpable tumour was found, hard and mobile There was no visible peristalsis, diarrhœa, or wasting A provisional diagnosis of carcinoma was given An *operation on April 30th last dis*played a tumour of the cæcum with hard nodules disseminated in the mesocolon and in wall of ileum, the glands were hard and enlarged This was apparently a typical dissemination of carcinoma, and it was *thought not to be removable, so* short circuiting was performed by lateral anastomosis *of the* ileum to the transverse colon A nodule *was removed, and* on microscopical examination proved to be typical tubercle 3 Plated Humerus for Ununited Fracture of *three months'* duration

This method of bandaging is extremely likely to give rise to adhesions fixing the arm and limiting greatly the movements of the arm subsequently; it is far better to leave the arm free. The chapter on bandaging is hardly required. A valuable section is that dealing with therapeutic immunisation and vaccine therapy, by Dr. George Sanborn, which occupies some 130 pages. It has evidently been written by one who is thoroughly acquainted with both the theory and practice of vaccine treatment.

The book is very fully illustrated, and most of the illustrations are clear and intelligible, but of a few it may be said that they give absolutely no information: as examples of the useless illustrations we may mention Fig. 45, "catheterisation of the female"; Fig. 150, "colostomy"; and Fig. 178, "second step in packing the vagina." We would not have it thought that we undervalue the many excellent illustrations which are to be found in this volume, but we feel that a protest should be made against the practice very prevalent at the present time of overloading books with reproductions of perfectly useless photographs. Photographs are easily obtained, and it is too often assumed that a photograph must be accurate, so that there is a tendency to employ photographs in cases in which, if any illustration is needed, a clear diagram would be much more instructive.

The Bacterial Diseases of Respiration and Vaccines in their Treatment. By R. W. ALLEN, M D., B.Sc. Lond., late editor *Journal of Vaccine Therapy*, &c. London: H. K. Lewis. 1913. Pp. 236. Price 6*s*. net.

So short a period has elapsed since we had occasion to notice the new edition of Dr. Allen's work on Vaccine Treatment, in which the question of respiratory troubles was pretty adequately dealt with, that the appearance of this fresh volume rather takes away one's breath The enthusiasm of the author, who believes that "in no other disorders are such uniformly successful results achieved" as in this group of troubles, is doubtless the cause of this further addition to the literature of the subject. The present book deals in successive chapters with the bacteriology of the respiratory tract in health, with methods of investigation and technique, both of staining and culture, with the bacterial findings in various respiratory affections, and with the general principles of vaccine treatment. The last six chapters then take up in turn the particular applications of the method to diseases of the upper respiratory passages, to bronchitis and asthma, to pneumonia and its complications, to a varied group of disorders, including whooping-cough, ozæna, pyorrhœa, and so forth, to mixed infections in pulmonary tuberculosis, and finally to specific remedies for tuberculosis itself.

The book contains much that is of interest. The attention which Dr. Allen has devoted to a study of the bacteriology of "common colds" is well known and deserves all praise. He now attempts to differentiate by their clinical symptoms the varieties of colds caused by the different micro-organisms. These distinctions will need confirmation by others before they can be unreservedly accepted, and we feel that much difficulty will arise in drawing distinctions in this field, since one cold differs from another by almost innumerable degrees of unpleasantness. Nevertheless, it is well to make at least an attempt at clinical accuracy, which may at any rate serve as a basis for further investigation. With regard to pneumonia Dr. Allen holds that in some individuals the pneumococcus is constantly lying in wait in the air-passages and gets its chance owing to some lowering of resistance. It is disappointing that an instance which he quotes, in which these germs persisted, showed that it was practically impossible to dislodge them by vaccines. In the vexed field of asthma the author confesses that his "observations upon the vaccine treatment of asthma have by no means reached finality"—a commendable instance of modesty; and throughout the book he recognises that ordinary methods of treatment are not to be omitted, even by the confirmed vaccinist. On the whole, we are inclined to think that his advice with regard to this procedure in the case of acute disease of the antrum might be applied, as yet at any rate, to many conditions: "It is therefore with considerable hesitation that an expensive course of vaccine treatment should be suggested ...... until opportunity for spontaneous cure has been afforded and aided by ...... other usual remedial measures." The book shows evidence of haste in preparation, as in such phrases as "much likely to prove," and in references to "a subsequent number," "the scope of this paper," and so forth. Names such as "Frankel," "Friedlander," "Munchener," should be printed with a modified vowel—an error which we are surprised to find in the writings of one who quotes German literature with reasonable frequency.

Human Physiology By Professor LUIGI LUCIANI, Director of the Physiological Institute of the Royal University of Rome. Translated by FRANCES A. WELBY. Edited by Dr. M CAMIS, Institute of Physiology, University of Pisa. Vol. II London: Macmillan and Co, Limited. 1913. Pp. 558. Price 18*s*. net.

THE first volume of this work was reviewed in THE LANCET of July 1st, 1911 (p. 19). We welcome the second volume in its English garb, as it presents us with some aspects of the questions with which it deals which are not so familiar to English readers We refer more especially to the rather full account of the work done by Italian physiologists. The historical aspect and perspective of the several questions is always kept well in view, dates of important observations being freely inserted. To each chapter is appended a bibliography, which should be adequate for most readers.

The subjects discussed are the internal protective secretions, the whole question of digestion, excretion, and the skin. The titles of some of the chapters are suggestive, such as "External Digestive Secretions," "Internal Restitutive Secretions," and "Katabolic Constituents of the Urine." Under "Internal Protective Secretions" a very full and readable account is given of the ductless glands and what is known of their functions. In comparing ordinary œdema with the swelling in myxœdema, the translator uses the word "percussion," no doubt following the author quite accurately, where perhaps the more familiar phrase, pitting on pressure, would be more applicable. The historical development of the investigations is lucidly set forth, and the work of Italian observers noted. Under the head of Graves's disease we find the word "oesophthalmia" for exophthalmia. The author directs particular attention to the renal lesions which occur after extirpation of the entire thyro-parathyroid apparatus. The salivary glands are described as of the "racemose" type; to us they seem to be rather of the tubular type. Some criticisms are offered on the inferences drawn by observers as to the effects of secretin on the pancreatic secretion in the normal body. Indeed, throughout the whole volume many statements current in text-books are submitted to critical analysis. This is one of the merits of the work. We are introduced to a new word, "biligenic," on p. 138. Very interesting is the full account of Barbèra's work on the bile.

The mechanics and chemistry of digestion occupy a large part of the text. Surgeons might read with profit what the author has to say regarding the removal of part of the intestine in the human subject, and several cases are cited where a very considerable length of the intestine has been the dissected axilla. This method of bandaging is extremely likely to give rise to adhesions fixing the arm and limiting greatly the movements of the arm subsequently; it is far better to leave the arm free. The chapter on bandaging is hardly required. A valuable section is that dealing with therapeutic immunisation and vaccine therapy, by Dr. George Sanborn, which occupies some 130 pages. It has evidently been written by one who is thoroughly acquainted with both the theory and practice of vaccine treatment.

The book is very fully illustrated, and most of the illustrations are clear and intelligible, but of a few it may be said that they give absolutely no information: as examples of the useless illustrations we may mention Fig. 45, "catheterisation of the female"; Fig. 150, "colostomy"; and Fig. 178, "second step in packing the vagina." We would not have it thought that we undervalue the many excellent illustrations which are to be found in this volume, but we feel that a protest should be made against the practice very prevalent at the present time of overloading books with reproductions of perfectly useless photographs. Photographs are easily obtained, and it is too often assumed that a photograph must be accurate, so that there is a tendency to employ photographs in cases in which, if any illustration is needed, a clear diagram would be much more instructive.

The Bacterial Diseases of Respiration and Vaccines in their Treatment. By R. W. ALLEN, M D., B.Sc. Lond., late editor *Journal of Vaccine Therapy*, &c. London: H. K. Lewis. 1913. Pp. 236. Price 6*s.* net.

So short a period has elapsed since we had occasion to notice the new edition of Dr. Allen's work on Vaccine Treatment, in which the question of respiratory troubles was pretty adequately dealt with, that the appearance of this fresh volume rather takes away one's breath The enthusiasm of the author, who believes that "in no other disorders are such uniformly successful results achieved" as in this group of troubles, is doubtless the cause of this further addition to the literature of the subject. Human Physiology By Professor LUIGI LUCIANI, Director of the Physiological Institute of the Royal University of Rome. Translated by FRANCES A. WELBY. Edited by Dr. M CAMIS, Institute of Physiology, University of Pisa. Vol. II London: Macmillan and Co, Limited. 1913. Pp. 558. Price 18*s.* net.

THE first volume of this work was reviewed in THE LANCET of July 1st, 1911 (p. 19). We welcome the second volume in its English garb, as it presents us with some aspects of the questions with which it deals which are not so familiar to English readers We refer more especially to the rather full account of the work done by Italian physiologists. The historical aspect and perspective of the several questions is always kept well in view, dates of important observations being freely inserted. To each chapter is appended a bibliography, which should be adequate for most readers.

The subjects discussed are the internal protective secretions, the whole question of digestion, excretion, and the skin. The titles of some of the chapters are suggestive, such as "External Digestive Secretions," "Internal Restitutive Secretions," and "Katabolic Constituents of the Urine." Under "Internal Protective Secretions" a very full and readable account is given of the ductless glands and what is known of their functions. In comparing ordinary œdema with the swelling in myxœdema, the translator uses the word "percussion," no doubt following the author quite accurately, where perhaps the more familiar phrase, pitting on pressure, would be more applicable. The historical development of the investigations is lucidly set forth, and the work of Italian observers noted. Under the head of Graves's disease we find the word "oesophthalmia" for exophthalmia. The author directs particular attention to the renal lesions which occur after extirpation of the entire thyro-parathyroid apparatus. The salivary glands are described as of the "racemose" type; to us they seem to be rather of the tubular type. Some criticisms are offered on the inferences drawn by observers as to the effects of secretin on the pancreatic secretion in the normal body. Indeed, throughout the whole volume many statements current in text-books are submitted to critical analysis. This is one of the merits of the work. We are introduced to a new word, "biligenic," on p. 138. Very interesting is the full account of Barbèra's work on the bile.

The mechanics and chemistry of digestion occupy a large part of the text. Surgeons might read with profit what the author has to say regarding the removal of part of the intestine in the human subject, and several cases are cited where a very considerable length of the intestine has been with sanatorium, sickness, and maternity benefits and the finances of an Insurance Committee. The special provisions applying to Scotland and Ireland are also given. Numerous specimen forms for use in connexion with medical and sanatorium benefit, and so forth, are given in appendices, and also a list of addresses of clerks to Insurance Committees in the British Isles. The selection of the material dealt with shows great discrimination, and we congratulate the author upon having produced a convenient and useful reference book.

Die Chirurgischen Untersuchungsmethoden, Lehrbuch für Studierende und Aerzte. Von Professor Dr HUBERT GEBELE. Mit 154 Abbildungen. München: J. F. Lehmann. 1912. Pp. 192. Price, paper, 8 marks; bound, 9 marks.

THIS book contains an account of the various methods which can be employed in the diagnosis of surgical cases. It describes how to employ inspection, palpation, percussion, and auscultation; it explains the use of the stomach tube; it gives directions for lumbar puncture and puncture of the brain, and points out what may be learned from the employment of such methods. Then come descriptions of the modes of examining the various secretions, excretions and exudations. Serum diagnosis has a chapter to itself, and the final chapters deal with the methods of endoscopy and with radiography. It may be thought that it would not be possible to put all this information into so small a compass, but the author has succeeded very well in the task which he had set himself, for he has supplied those particulars and details which are so often wanting in the usual text books on surgery. The numerous illustrations should assist the reader.

MISCELLANEOUS VOLUMES

OF the making of books for mothers on the puerperal condition and the care of children there seems to be no end, but the ideal book or books on those subjects have not yet appeared. Certainly they are not to be found in either *The Young Mother* or *Babyhood*, by J. BERNARD DAWSON, M.D. Lond., F.R.C.S. (London: Ewart Seymour, and Co., Limited. 1912. Price 2*s.* 6*d.* net each). Both books, it is true, contain a good deal of common sense information, but both also contain much detailed and strictly professional information with which it is both unnecessary and undesirable that the lay person should be indoctrinated. We objected, for instance, when reviewing a similar work some time back, to a discussion in such a place of the merits and demerits of chloroform anæsthesia in confinements, and we make the same objection concerning "The Young Mother." The author should dissociate himself from responsibility for the second appendix, which is, in effect, a running commentary of approval of the various foods, toilet preparations, proprietary remedies, and so forth that are advertised on the opposite pages, and which is apparently identical in both books.——A useful manual for maternity nurses is *Babies*, by MARGARET FRENCH, Sister at the General Lying-in Hospital, Lambeth (London: Macmillan and Co. 1913. Pp. 80. Price 1*s.* net). It is full of practical information, based on scientific sources, and digested for assimilation by those for whom it is intended. The information given is judiciously selected and expressed without any professional parade. We would suggest, however, that owing to the grave importance of preventive measures in regard to ophthalmia neonatorum and the widespread nature of the infection, some reference should be made to it at the outset when, as on pp. 6 and 14, the care of the eyes is referred to. Every new-born child without exception should be watched for it, no matter what the status of its parents may be. The book can be heartily commended.——Another "baby book" is *Our Baby*, by Mrs. J. LANGTON HEWER (Bristol: John Wright and Sons, Limited. 1913. Pp. 192. Boards 1*s.* 6*d.* net, cloth 2*s.* 6*d.* net), which, as it has now reached its fourteenth edition, completing the issue of one hundred thousand copies, must be held to have established its popularity. It contains much wholesome advice on many points in the rearing of children, besides the mere instruction as to washing, dressing, exercise, sleep, simple ailments, &c. We can endorse the opinion uttered by the author in the first edition (1891) that "it would certainly raise the standard of health in the next generation if every girl were obliged, before leaving school, to pass an examination on the very important subject of 'How to bring up a Baby.'" The present edition has been revised and much new matter added, but the revision is hardly perfect, for on p. 2 a reference is given to p. 166, but on turning to that page we find nothing relating to the subject (boracic lotion) for which the reference was made. The additions concern infant feeding, the nursing of sick children, moral training, and tuberculosis; also a chapter on the Special Care of Children in Tropical Countries.

For the purposes of mere review or enumeration, so as to avoid overlooking one or more of a series of points in a group, memoriæ technicæ are very useful and nothing can be urged against their proper use. Dr. N. CORBET FLETCHER'S *Compendium of Aids to First Aid* (London: John Bale, Sons, and Danielsson, Limited. 1913. Pp. 45. Price 6*d.* net) consists of a very ingenious series of mnemonic "tips" for those who have thoroughly mastered the principles of first aid, which will be as useful in checking off the items of their knowledge as an instrument list is at operation.——The *Indian Manual of First Aid*, by Major R. J. BLACKHAM, R.A.M.C. (Calcutta: Thacker, Spink and Co. 1913. Pp. 174. Price R.1) has been prepared especially to meet the requirements of the Indian branch of the St. John Ambulance Association. It follows the syllabus of instruction of the association. We should like to see a reference to the immediate application of a hot saturated solution of boric acid as an application to burns.——It is unnecessary to do more than repeat the commendation already expressed in these columns of Lieutenant-Colonel P. C. GABBETT'S *Manual for Women's Voluntary Aid Detachments* (Bristol: John Wright and Sons, Limited. Pp. 115. Price 1*s.* net), the second revised and enlarged edition of which is before us. Additions have been made especially in regard to the treatment of wounds and combined work, and chapters have been added on Camp Kit for Nurses and the Red Cross Society's arrangements for training.——Only a little over a year ago we noticed the seventh edition of *First Aid to the Injured and Sick, an Advanced Ambulance Handbook*, by Major F. J. WARWICK, R.A.M.C. (T.) and Major A. C. TUNSTALL, R.A.M.C. (T.), and now the eighth edition (Bristol: John Wright and Sons, Limited. 1913. Pp. 246. Price, boards, 1*s.* net; leather, 2*s.* 6*d.* net) is before us. It is an advanced book, and goes quite fully into the subject, so that it will be of service to ambulance lecturers, as well as to pupils who have attained a fair degree of proficiency. Part I. gives an account of the structure and functions of the body in a more detailed degree than is customary in first aid manuals. Part II. deals with bandaging and the usual emergencies and includes the new stretcher drill from the Royal Army Medical Corps Training, 1911. A book that has reached its eightieth thousand calls for no further comment.——Four little books, the first of the new S.P. Pocket Guide Series, published by the Scientific Press, Limited, London, price 1*s.* net each, may fitly be mentioned here. *Bandaging Made Easy*, by Miss M. R. HOSKING, Sister-in-charge, Tredegar House, Bow, E., is an admirably clear and concise little handbook, well illustrated. The with sanatorium, sickness, and maternity benefits and the finances of an Insurance Committee The special provisions applying to Scotland and Ireland are also given Numerous specimen forms for use in connexion with medical and sanatorium benefit, and so forth, are given in appendices, and also a list of addresses of clerks to Insurance Committees in the British Isles The selection of the material dealt with shows great discrimination, and we congratulate the author upon having produced a convenient and useful reference book

---

Die Chirurgischen Untersuchungsmethoden, Lehrbuch fur Studierende und Aerzte Von Professor Dr HUBERT GEBELE Mit 154 Abbildungen Munchen J F Lehmann 1912 Pp 192 Price, paper, 8 marks, bound, 9 marks

THIS book contains an account of the various methods which can be employed in the diagnosis of surgical cases It describes how to employ inspection, palpation, percussion, and auscultation, it explains the use of the stomach tube, it gives directions for lumbar puncture and puncture of the brain, and points out what may be learned from the employment of such methods Then come descriptions of the modes of examining the various secretions, excretions and exudations Serum diagnosis has a chapter to itself, and the final chapters deal with the methods of endoscopy and with radiography It may be thought that it would not be possible to put all this information into so small a compass but the author has succeeded very well in the task which he had set himself, for he has supplied those particulars and details which are so often wanting in the usual text books on surgery The numerous illustrations should assist the reader

---

MISCELLANEOUS VOLUMES

OF the making of books for mothers on the puerperal condition and the care of children there seems to be no end but the ideal book or books on those subjects have not yet appeared Certainly they are not to be found in either *The Young Mother* or *Babyhood* by J BERNARD DAWSON M D Lond, F R C S (London Ewart Seymour, and Co Limited 1912 Price 2s 6d net each) Both books it is true, contain a good deal of common sense information, but both also contain much detailed and strictly professional information with which it is both unnecessary and undesirable that the lay person should be indoctrinated We objected, for instance, when reviewing a similar work some time back, to a discussion in such a place of the merits and demerits of chloroform anæsthesia in confinements and we make the same objection concerning The Young Mother' The author should dissociate himself from responsibility for the second appendix, which is, in effect, a running commentary of approval of the various foods, toilet preparations, proprietary remedies, and so forth that are advertised on the opposite pages, and which is apparently identical in both books ——A useful manual for maternity nurses is *Babies*, by MARGARET FRENCH, Sister at the General Lying in Hospital, Lambeth (London Macmillan and Co 1913 Pp 80 Price 1s net) It is full of practical information, based on scientific sources, and digested for assimilation by those for whom it is intended The information given is judiciously selected and expressed without any professional parade We would suggest, however, that owing to the grave importance of preventive measures in regard to ophthalmia neonatorum and the widespread nature of the infection, some reference should be made to it at the outset when, as on pp 6 and 14 the care of the eyes is referred to Every new born child without exception should be watched for it, no matter what the status of its parents may be The book can be heartily commended ——Another "baby book" is *Our Baby*, by Mrs J LANGTON HEWER (Bristol John Wright and Sons, Limited 1913 Pp 192 Boards 1s 6d net, cloth 2s 6d net), which, as it has now reached its fourteenth edition, completing the issue of one hundred thousand copies, must be held to have established its popularity It contains much wholesome advice on many points in the rearing of children, besides the mere instruction as to washing, dressing, exercise, sleep, simple ailments, &c We can endorse the opinion uttered by the author in the first edition (1891) that ' it would certainly raise the standard of health in the next generation if every girl were obliged, before leaving school, to pass an examination on the very important subject of 'How to bring up a Baby' ' The present edition has been revised and much new matter added, but the revision is hardly perfect, for on p 2 a reference is given to p 166, but on turning to that page we find nothing relating to the subject (boracic lotion) for which the reference was made The additions concern infant feeding the nursing of sick children, moral training, and tuberculosis, also a chapter on the Special Care of Children in Tropical Countries

For the purposes of mere review or enumeration, so as to avoid overlooking one or more of a series of points in a group, memoriæ technicæ are very useful and nothing can be urged against their proper use Dr N CORBET FLETCHER'S *Compendium of Aids to First Aid* (London John Bale, Sons, and Danielsson Limited 1913 Pp 45 Price 6d net) consists of a very ingenious series of mnemonic "tips' for those who have thoroughly mastered the principles of first aid, which will be as useful in checking off the items of their knowledge as an instrument list is at operation ——The *Indian Manual of First Aid*, by Major R J BLACKHAM, R A M C (Calcutta Thacker, Spink and Co 1913 Pp 174 Price R 1) has been prepared especially to meet the requirements of the Indian branch of the St John Ambulance Association It follows the syllabus of instruction of the association We should like to see a reference to the immediate application of a hot saturated solution of boric acid as an application to burns ——It is unnecessary to do more than repeat the commendation already expressed in these columns of Lieutenant Colonel P C GARRETT'S *Manual for Women's Voluntary Aid Detachments* (Bristol John Wright and Sons, Limited Pp 115 Price 1s net), the second revised and enlarged edition of which is before us Additions have been made especially in regard to the treatment of wounds and combined work, and chapters have been added on Camp Kit for Nurses and the Red Cross Society's arrangements for training ——Only a little over a year ago we noticed the seventh edition of *First Aid to the Injured and Sick, an Advanced Ambulance Handbook*, by Major F J WARWICK, R A M C (T) and Major A C TUNSTALL, R A M C (T), and now the eighth edition (Bristol John Wright and Sons, Limited 1913 Pp 246 Price, boards, 1s net, leather, 2s 6d net) is before us It is an advanced book, and goes quite fully into the subject so that it will be of service to ambulance lecturers, as well as to pupils who have attained a fair degree of proficiency Part I gives an account of the structure and functions of the body in a more detailed degree than is customary in first aid manuals Part II deals with bandaging and the usual emergencies and includes the new stretcher drill from the Royal Army Medical Corps Training, 1911 A book that has reached its eightieth thousand calls for no further comment ——Four little books, the first of the new S P Pocket Guide Series, published by the Scientific Press Limited London, price 1s net each, may fitly be mentioned here *Bandaging Made Easy*, by Miss M R. HOSKING, Sister in charge, Tredegar House Bow, E, is an admirably clear and concise little handbook, well illustrated The this kind granted in the five years 1907–1911 They found that only nine of the licensing authorities had accepted certificates from candidates passing examinations by bodies who had not the privilege of giving registrable diplomas Fourteen of the licensing authorities said that they had given no such exemptions during that time Of the nine authorities who did grant exemptions, the Universities of Manchester and Bristol only gave exemption in one case each The former exempted from the first, second, and third examinations because the candidate was an M D of Geneva The latter granted exemption from the first professional examination as the candidate was an Associate of the Royal College of Science, London and M A, Ph D of Heidelberg The committee found that 124 exemptions had been granted by the Conjoint Board of England It was quite obvious that the high standing of its diplomas would naturally attract colonial and foreign surgeons who were desirous of obtaining a qualification to admit them to the Medical Register The committee had before them the percentage of the exemptions to the number qualified, but the majority of the bodies gave a very small percentage of exemptions to the numbers of persons who qualified Two licensing authorities seemed to grant these exemptions in a much larger proportion—the Apothecaries' Society of London and the Apothecaries' Hall of Dublin The percentage of the Apothecaries' Society of London was 8 9 per cent, but that of the Apothecaries' Hall of Dublin was 59 1 per cent The latter gave exemptions to 22 candidates and the number qualified was 37 The committee were asked whether the granting of exemptions of this kind should be continued It appeared to them that this was a question largely in the discretion of the licensing authorities themselves All the Council could do would be, if it became evident that exemptions were being granted on account of examinations of insufficient standard, to deal with them under their powers under the Medical Act Many of these exemptions were granted for examinations where it would be impossible to suggest that the standard was not adequate Last year a motion was adopted by the Council on the granting of exemptions on account of examinations passed by candidates in the Indian Subordinate Medical Department It was possible that some of the examinations which had been accepted by some of the bodies for exemption might be dealt with in the same way It was obvious that no general rule could be suggested In looking through the list the committee found that 117 candidates received exemptions on account of examinations which they had passed in the Dominion of Canada However, the Medical Council for the whole Dominion of Canada was coming into operation and the committee hoped that this was the beginning of what might perhaps be a very intimate mutual recognition of medical qualifications If this should prove to be the case it would do away with half the cases in the list of exemptions As to the conditions under which the various licensing bodies received such certificates of exemptions the Conjoint Board for England published a very complete list which had been compiled with great care, of the foreign and colonial examinations which they were willing to accept The Scottish and the Irish Conjoint Boards had similar lists The Apothecaries' Society of London stated in their regulations that they would grant exemption to candidates from all examinations except the final group on producing evidence that they had passed similar examinations to those conducted by boards recognised by the Society

Sir JOHN MOORE seconded the motion

Dr ADYE-CURRAN complained that Sir Charles Ball had made the Apothecaries Hall of Dublin a stalking horse The Hall would never accept any examination except that of a body which was recognised as satisfactory It appeared from the figures quoted by Sir Charles Ball that the Hall was very much in excess of other bodies granting exemptions That was not altogether its fault The Council had deprived it of its preliminary examination, and had thus endeavoured to prevent students entering on its curriculum Now the authorities of the Hall were twitted with the fact that most of their candidates had not put in their whole course at the Hall That was perfectly true, but the Council was to blame because it had deprived them of the means of obtaining students It seemed to him that there was a system of organised persecution directed against the Apothecaries' Hall

The motion was then agreed to.

The Apothecaries' Hall, Dublin

A report from the Examination Committee was also received regard to the Apothecaries Hall of Dublin

Sir CHARLES BALL said, in explaining the terms of the report, that the committee were of opinion that the reports of the assistant examiners on the methods and standards actually adopted at each qualifying examination should be discontinued They thought that the General Medical Council should not ask the assistant examiners to report to them on any portion of an examination except that which they conducted themselves [illegible] ecaries' Hall [illegible] committee [illegible] rom 1898 to 1907 one lived in London and the other in Scotland The Apothecaries' Hall complained, not without reason, of the heavy extra expenditure they were put to for the travelling and hotel expenses of these gentlemen In 1907 assistant examiners were appointed resident in Dublin, but instead of being nominated as formerly by a committee of the Council, the gentlemen nominated by the Apothecaries' Hall were appointed This arrangement had been continued ever since as vacancies had arisen the Apothecaries Hall having on each occasion nominated a well known hospital surgeon resident in Dublin, who had been accepted by the Council without question The Examination Committee considered reports of examinations made for the Council by a perfectly independent inspector preferable to those made by the nominees of the licensing body in question, no matter how distinguished those nominees might be The cost to the Council of these reports was considerable In 1911 it reached £148 4*s* 6*d* and in 1910 £120 16*s* 6*d* These sums included fees paid to the assistant examiners of £126 in 1911 and £105 in 1910 The Medical Act, 1886 Section 3, paragraph 3, stipulated that inspectors should not interfere with the conduct of any examination The assistant examiners could not, therefore, act as inspectors and there did not appear to be any warrant in the Act for the payment by the Council of fees to the assistant examiners The Examination Committee although they recommended the discontinuance of the reports on the entire final examinations furnished by the assistant examiners, did not consider it would be wise to dispense with all special investigation of these examinations The number of the exemptions granted to candidates by the Hall had been previously alluded to The committee however, had had a further return made of the number of exemptions granted by the Apothecaries' Hall on account of similar examinations held by universities and other licensing corporations whose qualifications did admit to registration The number was stated to be 29, this added to 22 gave a total of 51 candidates who obtained exemption from some part of their professional examinations during the period of five years 1907–1911 During the same time only 37 candidates passed the full examination in medicine, surgery and midwifery, and received the L A H wl [illegible] hat the number of [illegible] the necessary [illegible] who obtained ex [illegible] the qualification by 14 This was equivalent in itself to a considerable rejection rate without counting candidates who presented themselves more than once for examination or those, if any who went up for all their examinations at the Apothecaries' Hall without obtaining any exemption The returns as hitherto furnished by the Apothecaries' Hall to the Council did not show whether there were any candidates qualified who completed all their professional examinations at the Apothecaries Hall, but in view of the above figures, if there were any the number must have been extremely small It was obvious that the candidates who sought this diploma were almost, if not entirely those who had commenced their series of professional examinations elsewhere The Examination Committee thought that for the future the information required from the Apothecaries Hall as to exemptions, and the results of examinations should be given in such a way that the details of each candidate's course might be readily available for reference They suggested that, instead of submitting the information in the manner at present adopted it should appear for the future in the form of a table, in which the previous history of each candidate in reference to the earlier professional examinations and the results of the final examinations held by the Apothecaries' Hall would be at once apparent The this kind granted in the five years 1907–1911 They found that only nine of the licensing authorities had accepted certificates from candidates passing examinations by bodies who had not the privilege of giving registrable diplomas Fourteen of the licensing authorities said that they had given no such exemptions during that time Of the nine authorities who did grant exemptions, the Universities of Manchester and Bristol only gave exemption in one case each The former exempted from the first, second, and third examinations because the candidate was an M D of Geneva The latter granted exemption from the first professional examination as the candidate was an Associate of the Royal College of Science, London and M A , Ph D of Heidelberg The committee found that 124 exemptions had been granted by the Conjoint Board of England It was quite obvious that the high standing of its diplomas would naturally attract colonial and foreign surgeons who were desirous of obtaining a qualification to admit them to the Medical Register The committee had before them the percentage of the exemptions to the number qualified, but the majority of the bodies gave a very small percentage of exemptions to the numbers of persons who qualified Two licensing authorities seemed to grant these exemptions in a much larger proportion—the Apothecaries' Society of London and the Apothecaries' Hall of Dublin The percentage of the Apothecaries' Society of London was 8 9 per cent , but that of the Apothecaries' Hall of Dublin was 59 1 per cent The latter gave exemptions to 22 candidates and the number qualified was 37 The committee were asked whether the granting of exemptions of this kind should be continued It appeared to them that this was a question largely in the discretion of the licensing authorities themselves All the Council could do would be, if it became evident that exemptions were being granted on account of examinations of insufficient standard, to deal with them under their powers under the Medical Act Many of these exemptions were granted for examinations where it would be impossible to suggest that the standard was not adequate Last year a motion was adopted by the Council on the granting of exemptions on account of examinations passed by candidates in the Indian Subordinate Medical Department It was possible that some of the examinations which had been accepted by some of the bodies for exemption might be dealt with in the same way It was obvious that no general rule could be suggested In looking through the list the committee found that 117 candidates received exemptions on account of examinations which they had passed in the Dominion of Canada However, the Medical Council for the whole Dominion of Canada was coming into operation and the committee hoped that this was the beginning of what might perhaps be a very intimate mutual recognition of medical qualifications If this should prove to be the case it would do away with half the cases in the list of exemptions As to the conditions under which the various licensing bodies received such certificates of exemptions the Conjoint Board for England published a very complete list which had been compiled with great care, of the foreign and colonial examinations which they were willing to accept The Scottish and the Irish Conjoint Boards had similar lists The Apothecaries' Society of London stated in their regulations that they would grant exemption to candidates from all examinations except the final group on producing evidence that they had passed similar examinations to those conducted by boards recognised by the Society

Sir JOHN MOORE seconded the motion

Dr ADYE-CURRAN complained that Sir Charles Ball had made the Apothecaries Hall of Dublin a stalking horse The Hall would never accept any examination except that of a body which was recognised as satisfactory It appeared from the figures quoted by Sir Charles Ball that the Hall was very much in excess of other bodies granting exemptions That was not altogether its fault The Council had deprived it of its preliminary examination, and had thus endeavoured to prevent students entering on its curriculum Now the authorities of the Hall were twitted with the fact that most of their candidates had not put in their whole course at the Hall That was perfectly true, but the Council was to blame because it had deprived them of the means of obtaining students It seemed to him that there was a system of organised persecution directed against the Apothecaries' Hall

The motion was then agreed to.

The Apothecaries' Hall, Dublin

A report from the Examination Committee was also received regard to the Apothecaries Hall of Dublin

Sir CHARLES BALL said, in explaining the terms of the report, that the committee were of opinion that the reports of the assistant examiners on the methods and standards actually adopted at each qualifying examination should be discontinued They thought that the General Medical Council should not ask the assistant examiners to report to them on any portion of an examination except that which they conducted themselves [illegible] ecaries' Hall [illegible] committee [illegible] rom 1898 to 1907 one lived in London and the other in Scotland The Apothecaries' Hall complained, not without reason, of the heavy extra expenditure they were put to for the travelling and hotel expenses of these gentlemen In 1907 assistant examiners were appointed resident in Dublin, but instead of being nominated as formerly by a committee of the Council, the gentlemen nominated by the Apothecaries' Hall were appointed This arrangement had been continued ever since as vacancies had arisen the Apothecaries Hall having on each occasion nominated a well known hospital surgeon resident in Dublin, who had been accepted by the Council without question The Examination Committee considered reports of examinations made for the Council by a perfectly independent inspector preferable to those made by the nominees of the licensing body in question, no matter how distinguished those nominees might be The cost to the Council of these reports was considerable In 1911 it reached £148 4s 6d and in 1910 £120 16s 6d These sums included fees paid to the assistant examiners of £126 in 1911 and £105 in 1910 The Medical Act, 1886 Section 3, paragraph 3, stipulated that inspectors should not interfere with the conduct of any examination The assistant examiners could not, therefore, act as inspectors and there did not appear to be any warrant in the Act for the payment by the Council of fees to the assistant examiners The Examination Committee although they recommended the discontinuance of the reports on the entire final examinations furnished by the assistant examiners, did not consider it would be wise to dispense with all special investigation of these examinations The number of the exemptions granted to candidates by the Hall had been previously alluded to The committee however, had had a further return made of the number of exemptions granted by the Apothecaries' Hall on account of similar examinations held by universities and other licensing corporations whose qualifications did admit to registration The number was stated to be 29, this added to 22 gave a total of 51 candidates who obtained exemption from some part of their professional examinations during the period of five years 1907–1911 During the same time only 37 candidates passed the full examination in medicine, surgery and midwifery, and received the L A H wl [illegible] hat the number of [illegible] the necessary ex [illegible] who obtained the qualification by 14 This was equivalent in itself to a considerable rejection rate without counting candidates who presented themselves more than once for examination or those, if any who went up for all their examinations at the Apothecaries' Hall without obtaining any exemption The returns as hitherto furnished by the Apothecaries' Hall to the Council did not show whether there were any candidates qualified who completed all their professional examinations at the Apothecaries Hall, but in view of the above figures, if there were any the number must have been extremely small It was obvious that the candidates who sought this diploma were almost, if not entirely those who had commenced their series of professional examinations elsewhere The Examination Committee thought that for the future the information required from the Apothecaries Hall as to exemptions, and the results of examinations should be given in such a way that the details of each candidate's course might be readily available for reference They suggested that, instead of submitting the information in the manner at present adopted it should appear for the future in the form of a table, in which the previous history of each candidate in reference to the earlier professional examinations and the results of the final examinations held by the Apothecaries' Hall would be at once apparent The of economy were also apparently responsible for the combination of an equal quantity of turpentine with the oil used in the paint. Consequently it failed to dry quickly, and was still gelatinous and could be rubbed off with a finger long after it had been applied. This state of affairs was also due to the damp, ill-ventilated condition of the building, in which moulds were found in large quantities. It is, therefore, not strange that sufficient arsenical gases were set free to cause alarming symptoms. These, as is natural, were most severe in the cold seasons of the year; in the summer, when the windows were open, there were relatively few complaints. Arsenical poisoning frequently occurs in Sweden; indeed, 8 per cent. of the patients in the outbreak described had previously suffered. This is largely due to erratic legislation, stringent regulations having defeated their own ends. In view of the recent events just recorded alterations for the better may be anticipated.

THE DIETING OF PATIENTS IMMEDIATELY BEFORE GIVING ANÆSTHETICS FOR SURGICAL OPERATIONS

THERE is nothing about which opinions have undergone more change during the past decade than about the treatment of patients antecedent to their taking a general anæsthetic. In a review of a book upon surgical after-treatment, which appears in another column (p. 1594), this important subject is briefly alluded to, but it is worth more notice than is there given, because the fluctuations of view have led to much misapprehension. Many of the recent books dealing with surgical operations are often at fault and are, in the main, quite misleading. No doubt such manuals are restricted through the exigencies of space from entering fully into a subject which is extremely wide and demands a liberal space if it is to be treated at all adequately. The well-meant attempt to condense rules and formulate a general programme of treatment results in a hazy and even inaccurate series of statements which leave in the mind of the student or inexperienced practitioner a condition of confusion worse confounded. Dealing with a very narrow aspect of the matter, the question of giving or withholding all solid and liquid food for some hours before the anæsthetisation, we find the most conflicting views advanced. The dangers of a very prolonged fast have become recognised, and some surgeons have suggested the plan of persistence in the ordinary routine of meals, but allowing an interval to elapse between the last meal and the operation sufficiently long to permit of normal digestion. This plan, however, is open to an obvious objection. An individual about to undergo an operation is usually in far from a normal state, and his digestion and metabolism are either delayed or brought to a standstill. The more commonly accepted method is to preserve the customary meal times, but to diet the patient for some days, so that as light a task as possible is imposed upon his digestion. When the question of the ingestion of liquids is considered, we find some authorities urge that even water taken immediately before the anæsthetic will delay narcosis and provoke vomiting, while others support the view that after-sickness is often lessened by pre-anæsthetic libation of water. Probably the latter view is correct, provided that a sufficiently long interval of time elapses between the drinking and the anæsthetic, especially if the fluid taken is mildly alkaline and is at blood temperature. Certainly in the case of laparotomies a system of giving hot water made mildly alkaline and taken at four-hour intervals for a week before the operation subserves two useful purposes. It lessens post-anæsthetic vomiting and obviates the distressing thirst which is often an intolerable sequela in such cases. These are some of the procedures in common vogue but no wise practitioner will pin his faith to a routine following of any one of them. The peculiarities of each patient, and the exigencies of each operation have to be carefully weighed in deciding the method to be pursued for any given individual, and the accuracy of the judgment arrived at must depend in no small measure upon the experience and width of outlook enjoyed by the practitioner to whom is committed the ordering of the case.

SANATORIUM BENEFITS IN BIRMINGHAM

A COMMUNICATION from our correspondent in Birmingham last week expressed, under this heading, the opinion that there was a good deal of dissatisfaction in the medical profession with the way in which the treatment of the consumptive patients was being carried out. We are informed that these words have given a wrong impression, and also that no patient is recommended for or receives tuberculin unless he has been previously examined by the tuberculosis officer or one of the full-time assistants. The tuberculosis officer is himself specially trained and experienced in this branch of medicine, and high opinions have been expressed of his work at Birmingham under the National Insurance Act.

THE PHARMACEUTICAL SOCIETY

ON the occasion of the annual meeting of the Pharmaceutical Society, which was held on May 21st, the President, Mr. C. B. Allen, was able to give an account of a year's good work, and to show that after an existence of 72 years the society is in a stronger position than ever. The membership, which consists of 7522 registered pharmacists, is larger by 2000 than it was ten years ago, the funds are in a satisfactory condition, and "with regard to political influence," said the President, in moving the adoption of the annual report, "the council has been able, with the support of the chemists of the country as a whole, to make pharmacy felt in some quarters, feared in others, and respected on every hand." The period covered by the annual report, which was unanimously adopted by the meeting, was an anxious one, and although certain dangers which threatened pharmacists have not entirely passed away, the tension has been greatly relieved and the prospects are much brighter than they were a year ago. One cause of anxiety was the attempt made by an organised body of unqualified shopkeepers to obtain some of the privileges of pharmacists without the necessity of passing the pharmaceutical examinations. Stimulated by these non-registered persons, the Insurance Commissioners, a short time ago, appointed a committee of inquiry for the purpose of investigating the conditions under which medicines had been supplied prior to the passing of the Insurance Act, the object of those who pressed for the appointment of the committee being to secure the right to go on the chemists' panels. The report of this committee has not yet been made public, and its proceedings were private, but it may perhaps be inferred from the President's anticipation of the nature of the report that it is not unfavourable to pharmacists. He said that when the report was placed before the House of Commons registered persons would appreciate the dangers they had escaped and the means that ensured their safety. It seems that the society's witnesses before the committee had a most difficult task "to prove that neither logic nor reason could justify a policy that would condemn insured persons to have their medicines dispensed by unqualified persons who are under a legal disability created nearly 50 years ago." Another matter arising out of the Insurance Act to which the President drew attention was the of economy were also apparently responsible for the combination of an equal quantity of turpentine with the oil used in the paint Consequently it failed to dry quickly, and was still gelatinous and could be rubbed off with a finger long after it had been applied This state of affairs was also due to the damp, ill-ventilated condition of the building, in which moulds were found in large quantities It is, therefore, not strange that sufficient arsenical gases were set free to cause alarming symptoms These, as is natural, were most severe in the cold seasons of the year, in the summer, when the windows were open, there were relatively few complaints Arsenical poisoning frequently occurs in Sweden, indeed, 8 per cent of the patients in the outbreak described had previously suffered This is largely due to erratic legislation, stringent regulations having defeated their own ends In view of the recent events just recorded alterations for the better may be anticipated

THE DIETING OF PATIENTS IMMEDIATELY BEFORE GIVING ANÆSTHETICS FOR SURGICAL OPERATIONS

THERE is nothing about which opinions have undergone more change during the past decade than about the treatment of patients antecedent to their taking a general anæsthetic In a review of a book upon surgical after treatment, which appears in another column (p 1594), this important subject is briefly alluded to, but it is worth more notice than is there given, because the fluctuations of view have led to much misapprehension Many of the recent books dealing with surgical operations are often at fault and are, in the main, quite misleading No doubt such manuals are restricted through the exigencies of space from entering fully into a subject which is extremely wide and demands a liberal space if it is to be treated at all adequately The well meant attempt to condense rules and formulate a general programme of treatment results in a hazy and even inaccurate series of statements which leave in the mind of the student or inexperienced practitioner a condition of confusion worse confounded Dealing with a very narrow aspect of the matter, the question of giving or withholding all solid and liquid food for some hours before the anæsthetisation, we find the most conflicting views advanced The dangers of a very prolonged fast have become recognised, and some surgeons have suggested the plan of persistence in the ordinary routine of meals, but allowing an interval to elapse between the last meal and the operation sufficiently long to permit of normal digestion This plan, however, is open to an obvious objection An individual about to undergo an operation is usually in far from a normal state, and his digestion and metabolism are either delayed or brought to a standstill The more commonly accepted method is to preserve the customary meal times, but to diet the patient for some days, so that as light a task as possible is imposed upon his digestion When the question of the ingestion of liquids is considered, we find some authorities urge that even water taken immediately before the anæsthetic will delay narcosis and provoke vomiting, while others support the view that after sickness is often lessened by pre anæsthetic libation of water Probably the latter view is correct, provided that a sufficiently long interval of time elapses between the drinking and the anæsthetic, especially if the fluid taken is mildly alkaline and is at blood temperature Certainly in the case of laparotomies a system of giving hot water made mildly alkaline and taken at four hour intervals for a week before the operation subserves two useful purposes It lessens post-anæsthetic vomiting and obviates the distressing thirst which is often an intolerable sequela in such cases These are some of the procedures in common vogue but no wise practitioner will pin his faith to a routine following of any one of them The peculiarities of each patient, and the exigencies of each operation have to be carefully weighed in deciding the method to be pursued for any given individual, and the accuracy of the judgment arrived at must depend in no small measure upon the experience and width of outlook enjoyed by the practitioner to whom is committed the ordering of the case

SANATORIUM BENEFITS IN BIRMINGHAM

A COMMUNICATION from our correspondent in Birmingham last week expressed, under this heading, the opinion that there was a good deal of dissatisfaction in the medical profession with the way in which the treatment of the consumptive patients was being carried out We are informed that these words have given a wrong impression, and also that no patient is recommended for or receives tuberculin unless he has been previously examined by the tuberculosis officer or one of the full time assistants The tuberculosis officer is himself specially trained and experienced in this branch of medicine, and high opinions have been expressed of his work at Birmingham under the National Insurance Act

THE PHARMACEUTICAL SOCIETY

ON the occasion of the annual meeting of the Pharmaceutical Society, which was held on May 21st, the President, Mr C B Allen, was able to give an account of a year's good work, and to show that after an existence of 72 years the society is in a stronger position than ever. The membership, which consists of 7522 registered pharmacists, is larger by 2000 than it was ten years ago, the funds are in a satisfactory condition, and "with regard to political influence," said the President, in moving the adoption of the annual report, "the council has been able, with the support of the chemists of the country as a whole, to make pharmacy felt in some quarters, feared in others, and respected on every hand" The period covered by the annual report, which was unanimously adopted by the meeting, was an anxious one, and although certain dangers which threatened pharmacists have not entirely passed away, the tension has been greatly relieved and the prospects are much brighter than they were a year ago One cause of anxiety was the attempt made by an organised body of unqualified shopkeepers to obtain some of the privileges of pharmacists without the necessity of passing the pharmaceutical examinations Stimulated by these non registered persons, the Insurance Commissioners, a short time ago, appointed a committee of inquiry for the purpose of investigating the conditions under which medicines had been supplied prior to the passing of the Insurance Act, the object of those who pressed for the appointment of the committee being to secure the right to go on the chemists' panels The report of this committee has not yet been made public, and its proceedings were private, but it may perhaps be inferred from the President's anticipation of the nature of the report that it is not unfavourable to pharmacists He said that when the report was placed before the House of Commons registered persons would appreciate the dangers they had escaped and the means that ensured their safety It seems that the society's witnesses before the committee had a most difficult task "to prove that neither logic nor reason could justify a policy that would condemn insured persons to have their medicines dispensed by unqualified persons who are under a legal disability created nearly 50 years ago" Another matter arising out of the Insurance Act to which the President drew attention was the

THE GENERAL MEDICAL COUNCIL AND THE PROPOSED ALTERATION IN THE STANDARD OF PRELIMINARY EXAMINATIONS

BY SIR HENRY MORRIS, BART, M A, M B LOND, F R C S ENG

WHEN in November, 1910, the General Medical Council, with the object of raising the standard of preliminary education, resolved on making certain changes which were to date from Jan 1st, 1914, it was felt by some competent critics that the time for doing so was inopportune because of the falling off in the number of students entering the profession

It may be thought however, from the statement recently made as to an increase of 165 students registered in 1912 over the number registered in 1911, and as to the total number registered in the year 1912 coinciding with the average yearly *number of the preceding five years, that this* objection no longer exists

But the increase is apparent, not real It is due to the fact that a large number of students, owing to recently altered regulations, were enabled to register in 1912 instead of a year or so later, and when this number is discounted the real increase for the year 1912 is only 80, and the total number of entrants is considerably below the average of the previous five years, although it exceeds the total for the year 1911

What, however, *is of much greater importance than any* question as to the "how" and the "when" of raising the standard of existing examinations is the urgent need of the several universities and examining bodies of the United Kingdom uniting to foster the establishment of a recognised school leaving certificate, of a certificate which, without indicating a uniformity in kind of the education received and without pretending to imply an exact identity of standard, will yet be a sufficient proof of a sound general education to admit the holders of it to any university or to the *curriculum of study for any professional or scientific* calling

The entrance to a university or to a profession ought not to be barred by (in the words of Huxley) 'any absolute and defined preliminary examination, the passing of which shall be an essential condition of admission to the university' The instruction of a university or that required for any professional career, ought to be accessible to everyone who is fit to take advantage of it, although he may not have been prepared at school to pass a particular "absolute and defined preliminary examination'

It is the want of a universally recognised and accepted school leaving certificate which handicaps students and is so embarrassing to school masters It is this want which has been, and is, the chief obstacle in the way of many an excellent and accomplished student taking a university degree which otherwise he was fully competent to do, or changing from a profession for which he finds himself unfitted, or to which he has taken a dislike into one for which he has developed a liking and realises an aptitude It is the difference between the educational course they have pursued and the character of the particular entrance examination which they too late discover they have to pass, and not because their education and *grounding* are deficient or inferior, that under present circumstances keeps the door shut against many students who are even more capable and better instructed than some of those who have been allowed to pass through the portal

The General Medical Council could not exert its influence in a better cause than in reiterating its desire that the *Board of Education* and the *Oxford* and Cambridge School Examination Board should cooperate in getting established such a certificate, in soliciting the universities, the State, and the local authorities to take steps to standardise the different inspections by making the inspection a joint matter between them, in trying to induce the head masters of all the secondary schools in the country to have their schools officially inspected, and in urging the various universities and licensing bodies to accept such a school leaving certifi- [illegible] g else [illegible] of such a certificate the [illegible] the whole profession, would go a long way towards bringing about compulsory inspection of secondary schools if they could induce the universities and examining bodies of England to admit as candidates for their examinations (except, perhaps, in certain special cases) those only who have been educated at inspected schools

But [illegible] hed at home it would still b [illegible] of those Indian and colonia [illegible] ady are recognised, or who in future desire to be recognised by the General Medical Council, that information should be given to them as to what should be the scope, character, and standard of their preliminary examination in general education

The revision of the existing Recommendations of the Council whereby such information is at present conveyed alike to the examining bodies at home and in India and the Colonies has occupied much of the attention of the Education Committee since November, 1910 These Recommendations, which, on the joint advice of three educational experts, were adopted by the Council in 1900 and have ever since been in force, were with "three important changes" re affirmed in a report of the Education Committee in 1911 Two of these suggested "important changes" are (1) the increase of the percentage of marks required for the pass, and (2) the abolition of compensation between subjects This report of the Education Committee was merely entered on the minutes of the Council

Six months later—namely, in June, 1912—precisely the same proposals were again entered on the minutes of the Council On neither of these occasions was the approval of the *Council moved* On *both occasions, on the contrary*, a motion was proposed though not carried to refer the report back to the committee

In the reports of 1911 and 1912 the Sections I and II, which refer to "the character of the examination" and "the distribution of marks," are word for word the same as the Recommendations of the year 1900, whereas Section IV as to "the Minimum Percentage of Pass" is entirely different, the pass marks [illegible] recommended [illegible] *Recommendati* [illegible] compensation when the four subjects are taken at one examination "if the candidate reach the necessary percentage in the aggregate marks of his papers as a whole provided that the required pass mark must be reached in the English paper', whereas the reports of 1911 and 1912 suggest that 'no pass should be granted in any subject when the percentage gained in the subject is less than that which is stated in Section IV of those reports"

Again, Section VII of the Recommendations of 1900, which allows *of each of the four subjects of certain senior* [illegible] passed separately, is omitted from each of [illegible] Committee [illegible] Education Committee has been engaged in obtaining the opinions of the chief examining bodies, including those of India and the colonies on the proposals of the committee, and now after nearly 12 months' interval the committee has this week submitted a third report to the Council

On comparing Sections I and II of this last report—which *sections* were adopted by the Council yesterday (May 30th)—with the corresponding sections of the

THE GENERAL MEDICAL COUNCIL AND THE PROPOSED ALTERATION IN THE STANDARD OF PRELIMINARY EXAMINATIONS

BY SIR HENRY MORRIS, BART, M A, M B LOND, F R C S ENG

WHEN in November, 1910, the General Medical Council, with the object of raising the standard of preliminary education, resolved on making certain changes which were to date from Jan 1st, 1914, it was felt by some competent critics that the time for doing so was inopportune because of the falling off in the number of students entering the profession

It may be thought however, from the statement recently made as to an increase of 165 students registered in 1912 over the number registered in 1911, and as to the total number registered in the year 1912 coinciding with the average yearly number of the preceding five years, that this objection no longer exists

But the increase is apparent, not real It is due to the fact that a large number of students, owing to recently altered regulations, were enabled to register in 1912 instead of a year or so later, and when this number is discounted the real increase for the year 1912 is only 80, and the total number of entrants is considerably below the average of the previous five years, although it exceeds the total for the year 1911

What, however, is of much greater importance than any question as to the "how" and the "when" of raising the standard of existing examinations is the urgent need of the several universities and examining bodies of the United Kingdom uniting to foster the establishment of a recognised school leaving certificate, of a certificate which, without indicating a uniformity in kind of the education received and without pretending to imply an exact identity of standard, will yet be a sufficient proof of a sound general education to admit the holders of it to any university or to the curriculum of study for any professional or scientific calling

The entrance to a university or to a profession ought not to be barred by (in the words of Huxley) 'any absolute and defined preliminary examination, the passing of which shall be an essential condition of admission to the university' The instruction of a university or that required for any professional career, ought to be accessible to everyone who is fit to take advantage of it, although he may not have been prepared at school to pass a particular "absolute and defined preliminary examination'

It is the want of a universally recognised and accepted school leaving certificate which handicaps students and is so embarrassing to school masters It is this want which has been, and is, the chief obstacle in the way of many an excellent and accomplished student taking a university degree which otherwise he was fully competent to do, or changing from a profession for which he finds himself unfitted, or to which he has taken a dislike into one for which he has developed a liking and realises an aptitude It is the difference between the educational course they have pursued and the character of the particular entrance examination which they too late discover they have to pass, and not because their education and grounding are deficient or inferior, that under present circumstances keeps the door shut against many students who are even more capable and better instructed than some of those who have been allowed to pass through the portal

The General Medical Council could not exert its influence in a better cause than in reiterating its desire that the Board of Education and the Oxford and Cambridge School Examination Board should cooperate in getting established such a certificate, in soliciting the universities, the State, and the local authorities to take steps to standardise the different inspections by making the inspection a joint matter between them, in trying to induce the head masters of all the secondary schools in the country to have their schools officially inspected, and in urging the various universities and licensing bodies to accept such a school leaving certifi-

g else

of such a certificate the

the whole profession, would go a long way towards bringing about compulsory inspection of secondary schools if they could induce the universities and examining bodies of England to admit as candidates for their examinations (except, perhaps, in certain special cases) those only who have been educated at inspected schools

But hed at home it would still b of those Indian and colonia ady are recognised, or who in future desire to be recognised by the General Medical Council, that information should be given to them as to what should be the scope, character, and standard of their preliminary examination in general education

The revision of the existing Recommendations of the Council whereby such information is at present conveyed alike to the examining bodies at home and in India and the Colonies has occupied much of the attention of the Education Committee since November, 1910 These Recommendations, which, on the joint advice of three educational experts, were adopted by the Council in 1900 and have ever since been in force, were with "three important changes" re affirmed in a report of the Education Committee in 1911 Two of these suggested "important changes" are (1) the increase of the percentage of marks required for the pass, and (2) the abolition of compensation between subjects This report of the Education Committee was merely entered on the minutes of the Council

Six months later—namely, in June, 1912—precisely the same proposals were again entered on the minutes of the Council On neither of these occasions was the approval of the Council moved On both occasions, on the contrary, a motion was proposed though not carried to refer the report back to the committee

In the reports of 1911 and 1912 the Sections I and II, which refer to "the character of the examination" and "the distribution of marks," are word for word the same as the Recommendations of the year 1900, whereas Section IV as to "the Minimum Percentage of Pass" is entirely different, the pass marks

recommended

Recommendati

compensation when the four subjects are taken at one examination "if the candidate reach the necessary percentage in the aggregate marks of his papers as a whole provided that the required pass mark must be reached in the English paper', whereas the reports of 1911 and 1912 suggest that 'no pass should be granted in any subject when the percentage gained in the subject is less than that which is stated in Section IV of those reports"

Again, Section VII of the Recommendations of 1900, which allows of each of the four subjects of certain senior separately, is omitted from each of

Committee

Education Committee has been engaged in obtaining the opinions of the chief examining bodies, including those of India and the colonies on the proposals of the committee, and now after nearly 12 months' interval the committee has this week submitted a third report to the Council

On comparing Sections I and II of this last report—which sections were adopted by the Council yesterday (May 30th)—with the corresponding sections of the

100 feet to 1° F Readings with the wet bulb thermometer showed that at depths exceeding 2000 feet the atmosphere becomes drier, and the wet bulb gradient in consequence is much greater He said that the factors which influenced the temperature of mine air were increase of rock temperature due to depth, the rate of oxidation, the increase due to compression of air in the shafts, and the cooling effect due to taking up moisture He was convinced that the capacity of a man for work was seriously impaired when the wet-bulb temperature exceeds 82° F, although this figure may be exceeded if a strong breeze is made to blow over the exposed skin surface of the miner, but 85° F (wet bulb) must be taken as the limit To obtain proper working conditions Professor Cadman said that large volumes of air must be circulated through the main arteries of the mine to be delivered in the workings in a dry condition and at a temperature below 82° F (wet bulb) No artificial watering for the purpose of allaying dust should be used, and the air must be carried in roadways which permit of the minimum amount of loss of oxygen due to oxidation The length of coal face ventilated by a single air current must be so restricted as to prevent an abnormal increase in temperature due to oxidation Brisk currents of air must also be projected into the places where men are employed By adopting these precautions there should be no difficulty in successfully working to a depth of 5000 feet

Occupational Fatigue

SIR THOMAS OLIVER in introducing the subject, said that "so tired" was the cry of thousands of men, women, and children at the end of a working day, and how to meet the complaint and remove its cause was one of the problems of the present age He said that it would seem that the stress of modern times was becoming too great and that the strain of industrial methods through improved machinery was becoming more than human strength could bear Fatigue is due to altered industrial methods changes in the food of the people, overcrowding, and other conditions incidental to town life The greater prevalence of functional disease lends support to the supposition that men and women are more readily overcome by fatigue than were our forebears In factories, where the working day is unduly protracted not only are accidents more numerous but the actual production of the last hour or two is much below the average Night work for women and children is a frequent cause of fatigue and the employment of young persons in arduous processes requiring the lifting and carrying of heavy weights beyond their strength and years is not only a cause of fatigue but of arrested physical development Sir Thomas Oliver then proceeded to deal with long hours and overtime, working in continuous processes, the influence of alcohol, noise and a dusty atmosphere, as well as poverty, as causes of fatigue In the spinning department of a large cotton mill in Lancashire, which he had visited three months ago, he found men working at a temperature of 84° F and superintending 1360 spindles The men were constantly traversing the floor between the machines and there did not appear to be a minute to rest The severity of strain in this employment was so great that after 60 years of age workmen could not be kept in that department and other work had to be found for them A glance at the industrial progress of the second half of last century shows that, while the actual physical burden imposed upon workers has in many instances been lightened, the greater use of labour saving machinery has not only induced a degree of eyestrain and of muscular monotony, but has necessitated a fixation of mental attention far beyond anything hitherto required

Dr F SHUFFLEBOTHAM (Newcastle under Lyme) said that occupational fatigue was of the greatest importance, not only from a medical but also from an economic point of view, and these two aspects should be considered side by side The tendency of modern industry was not only to accelerate the processes of manufacture, but also to speed up the human machine, with the result that fatigue was one of the principal causes of both industrial diseases and accidents He then spoke of the influence of home surroundings and personal habits as factors in the production of fatigue, and said that small and crowded rooms, badly lighted and ventilated, with unsatisfactory sanitary arrangements, easily conduced to fatigue, while excess of alcohol and tobacco produced the same result He referred to the distance at which some workers lived from their work In some parts of England miners live six, seven, and even eight miles from the mine at which they are employed, and it is easy to understand that travelling such a distance twice a day in addition to the daily work, even though it be on a bicycle is a frequent cause of fatigue and in the course of time premature old age Miners who spend their leisure time in gardening are said to be affected in the same way, and in certain districts in Belgium where gardens have been attached to the miners' cottages it has been found that the output of coal per man has been considerably reduced although the working hours have been the same Dr Shufflebotham then spoke of the influence of high temperatures, and said that the new Home Office regulations with regard to the pottery industry fixed 125° F as the maximum temperature at which potters ovens should be drawn, and in view of the laborious work of the men so employed he thought it was too high This work was conducted, however, in a dry heat, and experienced workmen did not appear to be affected so much as those who commenced this kind of employment From a pathological point of view fatigue showed itself in two ways, either as arterio sclerosis in some form or other or else in such nervous diseases as writers' cramp or miners' nystagmus, both of which could be directly attributable to fatigue

Dr W F DEARDEN (Manchester) said that a moist atmosphere was undoubtedly essential to successful weaving in the cotton trade, and that the maximum temperature for weaving sheds was by law 65° F when taken with a wet bulb thermometer He specially referred to the fatigue produced among female operatives in Lancashire engaged in working at a sewing machine driven by electricity This is a comparatively new industry but one which is fast increasing, and he said that observations should be made upon the workgirls to find out to what extent they were affected by their employment Dr Dearden recommended that a medical examination be made of boys before their employment in mines, so that those unfit for the work of mining should be eliminated from the outset

Fustian cutting and Health

Dr J FORTUNE (Newcastle under Lyme) read an exhaustive and interesting paper upon the above subject He said that fustian cutting was a growing industry, and in Lancashire, Cheshire, and North Staffordshire about 12 000 people were employed in this way In many mills the work is entirely done by female labour, and he said it was almost unique in its demands on the locomotive powers the average daily distance which an operative walks being from 15 to 24 miles The majority of female workers work 10½ hours per day, but as the work is paid by piecework they rest when they like, and as it is purely manual work there is no mental strain involved, as there is in operatives who are responsible for the effective running of machinery Dr Fortune said that he had been unable to find any cases of phthisis among this class of workers and he explains this result to the fact that the physical conditions of the work have a weeding out influence He made a systematic examination of all the workers in 22 mills, and found that, generally speaking, the operatives were exceptionally healthy He had expected to find varicose veins flat feet and muscular cramp of the right forearm, but these preconceived ideas were entirely upset Constipation was uncommon and anæmia rare The pulse rate was observed under varying conditions, and he found that 55 per cent of the female workers between the ages of 13 and 17 had a pulse rate of over 100 but with advancing age the pulse rate became lower He thought that the quickened pulse rate in young girls was due to the fact that they walked quicker than the older workers

---

ROYAL SANITARY INSTITUTE —The annual report shows satisfactory progress and development in the institute s work both in England and other parts of the Empire A new branch has been established in New Zealand, and the total members and associates on the roll of the institute amount to 4257 An epitome of the three years' work since the institute was established in its new premises in Buckingham Palace-road is appended to the report, and shows that the change of premises was in every way satisfactory The new buildings have been paid for out of the accumulated fund, and the growth in the income has more than overtaken the increased expenses involved by the larger buildings

100 feet to 1° F Readings with the wet bulb thermometer showed that at depths exceeding 2000 feet the atmosphere becomes drier, and the wet bulb gradient in consequence is much greater He said that the factors which influenced the temperature of mine air were increase of rock temperature due to depth, the rate of oxidation, the increase due to compression of air in the shafts, and the cooling effect due to taking up moisture He was convinced that the capacity of a man for work was seriously impaired when the wet-bulb temperature exceeds 82° F, although this figure may be exceeded if a strong breeze is made to blow over the exposed skin surface of the miner, but 85° F (wet bulb) must be taken as the limit To obtain proper working conditions Professor Cadman said that large volumes of air must be circulated through the main arteries of the mine to be delivered in the workings in a dry condition and at a temperature below 82° F (wet bulb) No artificial watering for the purpose of allaying dust should be used, and the air must be carried in roadways which permit of the minimum amount of loss of oxygen due to oxidation The length of coal face ventilated by a single air current must be so restricted as to prevent an abnormal increase in temperature due to oxidation Brisk currents of air must also be projected into the places where men are employed By adopting these precautions there should be no difficulty in successfully working to a depth of 5000 feet

Occupational Fatigue

Dr J FORTUNE (Newcastle under Lyme) read an exhaustive and interesting paper upon the above subject He said that fustian cutting was a growing industry, and in Lancashire, Cheshire, and North Staffordshire about 12 000 people were employed in this way In many mills the work is entirely done by female labour, and he said it was almost unique in its demands on the locomotive powers the average daily distance which an operative walks being from 15 to 24 miles The majority of female workers work 10½ hours per day, but as the work is paid by piecework they rest when they like, and as it is purely manual work there is no mental strain involved, as there is in operatives who are responsible for the effective running of machinery Dr Fortune said that he had been unable to find any cases of phthisis among this class of workers and he explains this result to the fact that the physical conditions of the work have a weeding out influence He made a systematic examination of all the workers in 22 mills, and found that, generally speaking, the operatives were exceptionally healthy He had expected to find varicose veins flat feet and muscular cramp of the right forearm, but these preconceived ideas were entirely upset Constipation was uncommon and anæmia rare The pulse rate was observed under varying conditions, and he found that 55 per cent of the female workers between the ages of 13 and 17 had a pulse rate of over 100 but with advancing age the pulse rate became lower He thought that the quickened pulse rate in young girls was due to the fact that they walked quicker than the older workers

ROYAL SANITARY INSTITUTE —The annual report shows satisfactory progress and development in the institute's work both in England and other parts of the Empire A new branch has been established in New Zealand, and the total members and associates on the roll of the institute amount to 4257 An epitome of the three years' work since the institute was established in its new premises in Buckingham Palace-road is appended to the report, and shows that the change of premises was in every way satisfactory The new buildings have been paid for out of the accumulated fund, and the growth in the income has more than overtaken the increased expenses involved by the larger buildings decide if occasion arises all differences of opinion between the head of a department and such assessors

Constituent Colleges and University Departments.—The constituent colleges are to be educational institutions, either established by the University or strong enough in one faculty or more faculties to comply with the conditions for incorporation, and which transfer to the University the financial and educational control of their work in those faculties. A constituent college must be able to provide a full course for the first and higher degrees awarded in its faculty. The university departments will be departments dealing with a single subject of study, or with a group of studies of less range than a faculty, whether established by the University or placed under its financial and educational control. Each constituent college or university department is to be managed by a delegacy similar to those already appointed for University and King's Colleges, and will have a departmental organisation according to subjects of study. The head of each department will be either a professor or a reader. Classes and laboratory work will be confined to students of the University, and other students, though admitted to the general lectures, must be provided for separately. Royal scholarships and free studentships, tenable at the Imperial College, are to be confined to candidates qualified as undergraduates of the University.

The following is the Commissioners' summary of their recommendations in respect of the

Faculty of Medicine.

A Faculty of Medicine will be constituted when funds are available [illegible]

[illegible] of members of the medical profession who are not teachers of the [illegible] [illegible]r and mode of [illegible]

[illegible] ction will be [illegible] lifications and [illegible] niversity, but [illegible]

[illegible] ospital unit" will be [illegible] secure the coopera [illegible] the training of the [illegible]

[illegible] y, and biology will [illegible] Faculty of Medicine [illegible] subjects in the last [illegible] and be included in the higher [illegible] been taken at school, either [illegible] ing of the right standard or [illegible] on had followed other lines, [illegible] *nce laboratories of the Uni* [illegible] University for the purpose, [illegible] Medicine till [illegible]

[illegible] nd pharmaco [illegible] gy—including [illegible] nistry—will be [illegible] itals in which [illegible]

[illegible] cine will not [illegible] edical College, [illegible] *le, be brought* [illegible]

[illegible] ed when funds [illegible] y and mental [illegible] h the new hos [illegible]

[illegible] ablished, will [illegible] versity should [illegible] in dentistry to [illegible]

[illegible] nedical college [illegible] ication grants, [illegible] ry in order to [illegible] of university [illegible]

The First Constituent Colleges and University Departments

The following are recommended as the first constituent colleges and university departments, subject to the fulfilment in each case of certain conditions and in respect of certain faculties: The Imperial College of Science and Technology, the London School of Economics, University College, King's College, King's College for Women, Bedford College, London Day Training College, Royal Veterinary College, and Brown Animal Sanatory Institution.

Additional Income Needed.

In order to qualify the foregoing constituent colleges and university departments to take their place within the University, to establish an evening constituent college in the Faculties of Arts and Science at the Birkbeck College, to establish a University Department of Oriental Studies at the London Institution, and to maintain three constituent colleges in medicine attached to hospitals (as recommended above), the University will need additional income for—(*a*) professorships, readerships, and the maintenance of libraries and laboratories amounting to £85,500; and (*b*) reduction of fees to University students to £15 per annum for arts, £20 per annum for science, £30 per annum for technology—£13,500—making a total further income needed of £99,000 a year.

Area of the University for Constituent Colleges and University Departments.

The area of the University for the admission of constituent colleges and university departments is recommended to be that of the Administrative County of London, although the Commissioners look favourably upon certain logical extensions of that area suggested by Mr Sidney Webb

Site of University Quarter and Central University Buildings.

The constituent colleges and university departments of the University are to be concentrated as far as possible in Bloomsbury, and to this end King's College, and if possible the University Department of Household and Social Science and the Brown Animal Sanatory Institution, should be moved to Bloomsbury. The central University buildings, also in Bloomsbury, will include—(*a*) A great hall for University ceremonies and large educational gatherings. (*b*) Accommodation for the Senate, for committees, for the principal, and for the headquarters staff (*c*) Accommodation for the meetings of Convocation and for its officers. (*d*) A club house for the union societies, headquarters for the Officers' Training Corps, and rooms for professors, graduates, and students (*e*) A central university library supplementing the libraries in the constituent colleges, university departments, and schools Examination halls, in so far as they are required, are to be built in some accessible part of London where land is cheaper than in Bloomsbury.

Schools of the University.

Those public educational institutions or groups of departments in larger educational institutions which are not under the educational and financial control of the University will be schools of the University in compliance with the necessary conditions In the case of a hospital medical school the governing body is to appoint a committee of its own members, with the addition of University representatives and representatives of the teachers to conduct the business, and to this committee a board of teachers is to report. For every hospital medical school there is to be a group of teachers, each qualified by his attainments, his remuneration, and the conditions of his work, for university teaching and for the work entrusted to him; and the group must be collectively adequate to give instruction covering all the non-clinical subjects of the course for a degree in medicine which fall within the purview of the school In the case of schools which have transferred the teaching of the intermediate subjects to the University, only the later non-clinical subjects for which the school is responsible will fall within their purview

All institutions to be connected with the University (other than constituent colleges and university departments) will be schools of the University, and the present system of recognising teachers in institutions otherwise unconnected with the University will cease. Thus the teaching of mental diseases to university students in medical schools, not being constituent colleges, will be given by men who have received appointments in the medical school itself, and not by teachers individually recognised by the University at institutions which are not schools of the University. The statutory distinction between internal and external students will disappear, but a student graduating from a constituent college will place the name of his college after his degree, and a student graduating from a school that of his school

The following institutions which are at present schools of the University will be the first schools in medicine of the reconstituted University, provided they comply with the foregoing conditions.—The Medical School of St. Bartholomew's Hospital, the Medical College of the London Hospital, the Medical School of Guy's Hospital, the Medical School of St. Thomas's Hospital the Medical School of St George's Hospital, the Medical School of King's College Hospital, the Medical School of the Middlesex Hospital, the Medical School of St Mary's Hospital, the Medical School of Charing decide if occasion arises all differences of opinion between the head of a department and such assessors

A Garnishee Order in Respect of Medical Fees under the National Insurance Act.

An important legal question affecting medical men upon panels under the Insurance Act was recently raised at the Lambeth county court before his honour Judge Parry, who delivered a considered judgment. The matter arose out of the indebtedness of a medical practitioner to the plaintiff under an order for costs made recently against him in the High Court. The defendant being on the panel under the Insurance Act, was owed by the London Insurance Committee £33 for his services to insured patients. The plaintiff obtained a "garnishee" order under which the above sum was paid into the county court and a summons issued against the defendant, calling upon him to show cause why the money should not be paid out to the plaintiff. It may be mentioned that a garnishee order is in effect a warning to a person who owes money to another not to pay it over to him because it is claimed by the person who takes out the garnishee order. The money is then said to be "garnisheed," or, by old fashioned lawyers, "garnished," and the court takes charge of it, thus relieving the person who has it of the risk of paying it to the wrong person, in which event he might have to make it good to the right one. The novelty of the case as arising out of the Insurance Act was due no doubt to the obvious practical impossibility of garnishing fees paid, perhaps in very small sums, by a large number of patients to a medical practitioner. When the money is collected in one amount in the hands of an Insurance Committee the position is at once altered. The serious importance of the matter to a medical man whose patients may be wholly, or nearly so, insured persons arises out of the possibility that he may be deprived all at once of his income for a considerable period, in respect of a debt which otherwise he may arrange to pay by instalments. The question of the power to arrest a medical man's fees under the Insurance Act was at once raised by Judge Parry on the application to pay out the money in court being made before him, and he showed a sympathetic appreciation towards the possible hardships arising in such a matter throughout the argument, referring to the medical man's work under the Act as a public service which could only be rendered by one having the money to buy the necessaries of life. There was not, however, apparently any authority against the employment of the garnishee order in the circumstances described, and the learned county court judge adjourned the case after hearing argument in order that he might give the point further consideration. At a later date, in delivering his judgment, he said that the cases decided in the High Court laid down that a county court judge had full discretion as to the course that he should adopt in making an order for the payment of money out of court upon such an application as that before him. It was his duty to "temper the wind to the shorn lamb." He, therefore, proposed to follow the course that he was in the habit of following in making orders against judgment debtors. Upon this it was stated on behalf of the plaintiff that the defendant had 833 patients on his list and, on the other hand the defendant protested that he had no other patients from whom he could derive fees. His honour, in conclusion, made an order for the payment of £10 with costs to the plaintiff, the balance to be paid to the defendant. The point is one of interest to creditors and debtors, and the result of its submission to High Court, if the appeal takes place will be awaited with interest.

ASYLUM WORKERS' ASSOCIATION.—This association, the objects of which are to raise the status of asylum workers and to help them in times of need held its annual meeting in the rooms of the Medical Society, Chandos street London, W., on May 28th. Sir John Jardine M.P., presided. The annual report showed for the first time in several years a falling off in membership, though it is hoped that this backward movement is only a temporary one. Of life associate, and ordinary members there were 5860 in 1911, as compared with 4310 in 1912 the ordinary members for the same yea t the end of 1912 the the association, the

THE SEVENTEENTH INTERNATIONAL CONGRESS OF MEDICINE (1913)

INTERPRETERS WANTED.

IT is hoped that members of the Congress who speak foreign languages will be willing to wear a small badge denoting the language or languages which they can speak. Such an arrangement will be a great convenience to foreign visitors, and it is requested that those who will thus act as voluntary interpreters will communicate with the general secretary, 40 Wimpole street, W. He will be very grateful for their assistance.

SECTION OF RADIOLOGY.

This is the first time there has been a Section of Radiology included in the International Congress of Medicine, and every effort is being made to show that the advance in this branch of medical science fully justifies the formation of a separate section.

The section of which Sir James Mackenzie Davidson is President, deals with X ray work in all its branches and with radium therapy, but does not include electrotherapeutics. This subject is dealt with, as before, under the heading of Physiotherapy, a subsection of the Section of Therapeutics. Some little irritation is apparently felt on the continent at the non inclusion of electrotherapeutics. The formation of a separate Section of Radiology has, however, been entirely due to the energetic action of radiologists. There has been no special effort on the part of electrotherapeutists either to obtain a section for themselves or to be included in the Section of Radiology until too late, and therefore it behoves workers in this branch of medicine to see that they are more adequately represented at the next Congress.

With regard to the programme, the mornings are to be devoted to discussions of special interest and the afternoons to the reading of papers. A good lecture theatre has been secured in the new School of Mines at South Kensington, which can be completely darkened, and will be provided with a lantern for the demonstration of lantern slides; provision will also be made for the illumination of original negatives where this is considered necessary. In the museum a room will be set aside for the exhibition of transparencies, and adjoining this there will be a continuation of the department of radiology in which apparatus skiagrams and other daylight exhibits can be shown. Members wishing to exhibit should communicate direct with Mr. H. W. Armit, honorary secretary of the Museum Committee.

The following is the list of the discussions, together with the reporters selected for each. The Radiography of the Stomach and Intestines (Dr. Holzknecht and Dr. Leonard), that of the Chest (Dr. Hugh Walsham and Professor Wenckebach), the Radiotherapy of Malignant Disease (Dr. Abbé and Dr. Kienbock), Roentgen and Radium Therapy in Gynæcology, a joint discussion with the Section of Obstetrics and Gynæcology (Dr. Albers Schonberg, Dr. Foveau de Courmelles and Professor Kronig), the Radiography of Bones and Joints and its Value in Orthopædic Surgery, another joint discussion, this time with the Subsection of Orthopædics (Dr. Fedor Haenisch, Dr. Nové Josserand, and Dr. P. Redard).

Many offers of papers have been received, but the final selection of these has not yet been made. Preference will be given to papers received before April 30th, and no paper can be considered unless the title has been received by the secretary before July 1st. Any members wishing to read papers, who have not yet made application should communicate at once with Dr. G. Harrison Orton, honorary secretary, 67 Upper Berkeley street, Portman-square, London, W.

Everything possible is being done in the direction of the entertainment of foreign guests. A dinner will be held probably on August 8th, to which members may bring their lady friends, and the Electrotherapeutic Section of the Royal Society of Medicine and the Roentgen Society are ... nt to take place

tainment of foreign ladies but the ... present necessarily incomplete.

person who is asked to be bound by it can reject or accept it as he pleases

tainment of foreign ladies but the present necessarily incomplete six preceding weeks, had slightly declined to 1430 on Saturday last, 177 new cases were admitted during the week, against 206, 171, and 193 in the three preceding weeks These hospitals also contained on Saturday last 808 cases of diphtheria, 530 of measles, 299 of whooping cough, and 41 of enteric fever, but not 1 of small pox The 1116 deaths from all causes in London were 40 fewer than the number in the previous week, and were equal to an annual death rate of 12 9 per 1000 The deaths referred to diseases of the respiratory system, which had declined *from 255 to 186 in the four preceding weeks, further fell to* 162 last week, but were 19 in excess of the number recorded in the corresponding week of last year

Of the 4623 deaths from all causes in the 96 towns, 172 resulted from various forms of violence and 350 were the subject of coroners' inquests The causes of 24 or 0 5 per cent, of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest *All the causes of death were duly certified in* London and in 13 of its 14 suburban districts in Sheffield, Leeds Bristol, Bradford Hull Newcastle on Tyne, and in 60 other smaller towns The 24 uncertified causes of death last week included 4 in Birmingham, 3 in Liverpool 2 in Portsmouth, 2 in Stoke on Trent, and 2 in Sunderland

HEALTH OF SCOTCH TOWNS

In the 16 largest Scotch towns with an aggregate population estimated at 2 259 600 persons at the middle of this year, 1223 births and 724 deaths were registered during the week ended Saturday, May 31st The annual rate of mortality in these towns which had steadily declined from 17 7 to 16 3 per 1000 in the six preceding weeks, rose to 16 7 per 1000 in the week under notice During the *first nine weeks of the current quarter the mean annual* death rate in these Scotch towns averaged 17 0 against 14 4 per 1000 in the 96 large English towns Among the several towns the annual death rate last week ranged from 3 0 in Kilmarnock 6 1 in Ayr and 8 8 in Falkirk to 18 9 in Paisley and in Hamilton 20 1 in Greenock, and 24 7 in Aberdeen

The 724 deaths from all causes were 19 in excess of the number in the previous week, and included 107 which were referred to the principal epidemic diseases against 89 and 93 in the two preceding weeks Of these 107 deaths 40 resulted from whooping cough 33 from measles, 16 from infantile *diarrhœal diseases 7 from scarlet fever, 6 from* diphtheria, and 5 from enteric fever but not one from small pox These 107 deaths from the principal epidemic diseases were *equal to an annual death rate* of 2 5, against 1 1 per 1000 in the 96 large English towns The deaths attributed to whooping cough, which had been 45, *32* and *30* in the three preceding weeks rose to 40 last week and included 20 in Glasgow, 4 in Edinburgh, 3 in Aberdeen 3 in Leith, and 2 each in Paisley, in Greenock, and in Motherwell The deaths referred to measles which had been 30 33 and 40 in the three preceding weeks, declined to 33 last week, of this number 19 occurred in Glasgow, 12 in Aberdeen, and 2 in Dundee The fatal cases of diarrhœa and enteritis (among infants under 2 years of age) which had been 18 12 and 11 in the three preceding weeks, rose to 16 last week, 6 deaths were recorded in Glasgow, 3 in Dundee and 2 in Ab

1st East Anglian Field Ambulance, Royal Army Medical Corps: Captain Ernest V. Gostling to be Major (dated March 13th, 1913).

2nd East Anglian Field Ambulance, Royal Army Medical Corps: Thomas Aloysius Flynn to be Lieutenant (dated May 5th, 1913).

3rd Home Counties Field Ambulance, Royal Army Medical Corps: Alexander Hampton Brewer to be Lieutenant (dated May 2nd, 1913).

1st Wessex Field Ambulance, Royal Army Medical Corps: Frank Arthur Roper to be Lieutenant (dated April 22nd, 1913).

1st Southern General Hospital, Royal Army Medical Corps: Captain Walter J. Clarke resigns his commission (dated June 4th, 1913).

6th Battalion, The South Staffordshire Regiment: Surgeon-Captain Frederick Edge resigns his commission, and is granted permission to retain his rank and to wear the prescribed uniform (dated June 4th, 1913).

Attached to Units other than Medical Units.—Lieutenant Cecil Johnson to be Captain (dated Dec. 4th, 1912).

For attachment to Units other than Medical Units.—James Henry Crane to be Lieutenant (dated Jan. 22nd, 1913). Ernest Stanley Stork to be Lieutenant (dated April 23rd, 1913). Major James Stratton Warrack, from the 1st Home Counties Field Ambulance, Royal Army Medical Corps, to be Major (dated June 4th, 1913).

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

The under-mentioned Lieutenants to be Captains: William H. L. McCarthy (dated May 17th, 1913) and John Inkster (dated May 24th, 1913).

THE JAPANESE NAVAL MEDICAL DEPARTMENT IN THE RUSSO-JAPANESE WAR.

In the *Archives de Médecine et Pharmacie Navales* for March Médecin de 1re classe (Staff-Surgeon) Dr. Chemin presents a seventh, and, it is said, a final, instalment of his interesting translation of the official medical history of the Japanese Navy in the Russo-Japanese war. The war lasted from Feb. 9th, 1904, to Oct. 16th, 1905, and the average daily strength of the navy was 42,500, of whom there were in all killed or wounded 3692.

	Total.	Per 1000.
Killed	1883	44 7
Died from wounds	127	2·8
Invalided	153	3 5
Recovered	1529	35·8
	3692	86·8

The table speaks volumes for the efficiency of the Japanese surgeons. Included in these totals are the 1080 men drowned and 143 injured in the sinking of their ships. Of those actually damaged in battle half were injured in one or other of the three great battles, and their disposal was as follows:—

Casualties in the Fleet Actions per 1000 Injured or Killed.

	Russo-Japanese war.	In our French wars about 1800.
Killed in the three great battles	165	250
Died from wounds...	55	75
Invalided...	75	95
Recovered and went to duty ...	705	580
	1000	1000

Killed means people who died without having their wounds dressed even once; they were more numerous formerly, the ligature being scarcely known. The ships that lost most heavily were the *Yoshino* class, who had 37 per cent. casualties; the marine artillery at the siege of Port Arthur lost 35 per cent.; and the battleships 27 per cent., as did the torpedo flotillas. Admiral Togo's proud flagship *Mikasa* lost in battle more heavily than any other ship, 28 per cent., but 86 per cent. of the *Hatsuse's* crew were drowned when she foundered. Officers lost 17 per 1000; the navigating staff, always on the bridge (perhaps that is why), lost far more than any other group. The engine room staff had few wounds, but many deaths from drowning. The painstaking Japanese have divided the injuries into two groups, 2840 the direct result of the war (shells, fragments of ship, bullets and drowning) and 852 indirectly due to the war—rupture of membrana tympani or crush of hand by the mechanism of one's own gun. There are very neat and elaborate tables which will be useful to historians, and the medical profession should be grateful to the Japanese surgeons for so carefully putting so many interesting facts on record.

THE OLIVER-SHARPEY LECTURES.

To the Editor of THE LANCET.

SIR,—In common, I feel sure, with all who are interested in cardio-vascular physiology and pathology, I have read with pleasure and instruction Dr. A. D. Waller's Oliver-Sharpey Lectures on the Electrical Action of the Human Heart, reported in your issues of May 24th and 31st.

I shall not presume to offer any remarks on the purely physical section of his lectures, in which he has almost succeeded in rendering mathematics tolerable to the uncalculating mind, which is relieved when it discovers that the learned lecturer appears to have borrowed his phonetic symbol for the cantering rhythm from the Bucolics of Virgil, for I venture to think that Dr. Waller could complete the melodious line in which "*tegmine*" is the ultimate dactyl.

It is, indeed, upon this canter that I chiefly desire to comment, only premising my remarks on this subject by stating that I have also read with much interest Dr. Waller's account of auriculo-ventricular dissociation on pp. 1515–16, and merely remark in this connexion that I do not think the anatomy of the auriculo-ventricular bundle is yet sufficiently determined to be assumed to be common knowledge, nor, such as it is, a final conception of that structure.

The cantering rhythm is, as we know, a very common phenomenon met with at all ages and in hearts both with and without organic valvular disease. Explanations of the canter—that is, of the so-called "third sound"—which have hitherto been given have not been generally accepted. A year ago I asked an expert electrocardiographer what Einthoven's instrument had to say to the matter, but he confessed he had not noted the sign specially. It was with much pleasure, therefore, that I observed that Dr. Waller had dealt so fully with this sign, so well known to clinicians. His term "hemitachycardia" is, I think, likely to become current, and it is certainly to be preferred to "cantering," "galloping," or any other sesquipedalian word. One occasionally has the good fortune to meet with cases which in themselves reveal the whole gamut of cardiac irregularity, and are in themselves an epitome of variations in cardiac motion.

THE LANCET of Oct. 8th, 1910, contains a minute study of such a case which was under my care at the Great Northern Central Hospital, under the title "The Meaning of the Audible Signs in Mitral Stenosis." This case exhibited tachycardia, bradycardia, cantering rhythm, complete ventricular irregularity (auricular fibrillation), and the normal rhythm with which it was discharged from hospital. The only part of this paper to which I shall refer is my explanation of the cantering, or, as I called it, the triple rhythm, for which *tegmine* with a long and soft final vowel is certainly a more euphonious symbol than the "lup-lup-dup" which I employed. Dr. Waller makes the final vowel short, which distinguishes a quick from a slow canter, although the canter cannot be quickened much without being abolished and giving place to the ordinary first and second sounds of the heart, a condition which is constantly induced by making a patient evincing the canter in the recumbent position sit up in bed, when, with the acceleration and augmentation dependent upon movement, the added sound frequently disappears. In the paper which you published, and which was originally

In the paper which you published, and which was originally

Owing to want of space it is impossible to make adequate provision for our nurses, and most of the bedrooms are shared by two or three The question of the proper housing of the nursing staff was one in which the late Duke took the greatest personal interest, and in the hope of improving matters an appeal was made under his direction which resulted in some £2000 being subscribed towards a new " Home "

A further £10 000 is required to carry out the work, and it is earnestly hoped that sufficient help will be forthcoming to enable the late President s wish to be realised, and at the same time afford an opportunity for the board to associate his name for ever with a work which he had so much at heart

Contributions however small, will be very gratefully received and may be addressed to us at the hospital

We are, Sir, yours faithfully,
ARTHUR HILL
Chairman " Abercorn Memorial
Executive Committee
GEO F MARSHALL
June 3rd 1913 Chairman West London Hospital

PS —Up to the present a total sum of £3200 has been received

THE LATE MR JORDAN LLOYD

To the Editor of THE LANCET

SIR,—It has been decided to commemorate the work of the late Mr Jordan Lloyd by naming one of the surgical wards at Queen's Hospital after him

The medical staff are anxious to appeal, through your courtesy, to members of the profession in Birmingham and the Midlands to aid in the endowment of this ward They feel that those with whom Mr Jordan Lloyd worked for so many years, and many of whom owe so much to him as a teacher, would wish to be associated in contributing to the Memorial Fund

Cheques should be made payable to the Queen s Hospital (Jordan Lloyd Memorial Fund) and forwarded to Mr H F Keep, Queen's Hospital, Birmingham

I am, Sir, yours faithfully
DOUGLAS STANLEY,
Chairman of the Medical Committee
Queen s Hospital Birmingham June 3rd 1913

PROGERIA AND ATELEIOSIS

To the Editor of THE LANCET

SIR,—I should be obliged if you could afford space in THE LANCET for the following communication although it arrives so late upon the scene (Reasons for this will, I think be obvious)

In THE LANCET of Feb 1st of this year was a paper by Professor A Keith upon the subject of progeria and ateleiosis It is obvious in the case of ateleiosis that there is urgent need of post mortem examinations Such cases as that described by Rennie,[1] the condition of the sella turcica in Paltauf s case,[2] and the recent experimental work of the Italian school upon dogs (removal of the pituitary gland in young puppies), indicate that it is to the pituitary body that attention should be directed in the main But all recorded post mortem accounts are silent as to the condition of this structure in the cases examined

I wish to indicate (in case the fact should not be known already) to Mr Hastings Gilford, Professor Keith, and other readers of THE LANCET who are interested in this subject that there are the following cases of this condition (amongst many others) touring about Europe or America in " shows " and to submit that it would be deplorable if any of them were permitted to die without necropsy, for it would be a great waste of opportunity I may say that I have myself endeavoured to make arrangements for this to be done, but without any success and I have come to realise that only the great can bring this to pass, and that the efforts in this direction of such as myself will be as they have been, unavailing

There are the following cases of Mr Hastings Gilford s second group 1 The two brothers Magri (Primo and Ernesto—known as " Baron ' Magri) from Tuscany These have been described by Veratti Aged about 60 to 65 years It may be presumed that one or other may die before very long 2 The two brothers Heinrich and Bruno Glauer, from Innsbruck, Tyrol Aged about 26 and 22 years 3 Smaun Sing H Poo, from Burma, aged about 26 years He has been described by Virchow (There was another case in this family which died very young) This case is at present in Australia touring in a "freak" show 4 Ludwig Alpts, aged about 20 years, smaller than any of the others His mother, an aunt, and a female cousin are achondroplasic, while his reputed father was ateleiotic 5 A Turkish case of between 50 and 60 years of age, the name of which I forget

I hope, Sir, I shall be pardoned for writing as above It appears to be very important that as many of these cases as possible should be examined post mortem by one or other of the readers of THE LANCET I wish to call attention to their existence in case this is not generally known, in the hope that adequate examination may be made for one or more may die before very long in any part of the world

I am, Sir yours faithfully

ROBERT LISTON'S ANEURYSM

To the Editor of THE LANCET

SIR —Can any of your readers tell me where is the preparation of the aortic aneurysm taken from Robert Liston in 1847 ? It is not at University College, the Royal College of Surgeons, London or Edinburgh, Cambridge, or Norwich There is a persistent tradition that it is still in existence but I have not been able to locate it In all probability the preparation was put up by the late William Cadge who made the post mortem examination

I am, Sir, yours faithfully,
F WILLIAM COCK, M D Durh , F S A
1 Porchester Houses Porchester-square W May 29th 1913

SCARLET FEVER AND ITS CONGENERS

To the Editor of THE LANCET

SIR —In THE LANCET of Oct 13th 1894 there is an annotation on " some cases which recently happened in that parish (Fulham) and which simulated scarlet fever ' It seems as if the outbreak in Cheltenham and some other places of the malady described in the lay press is the same as that referred to in THE LANCET nearly 20 years ago A letter of the late Sir Samuel Wilks which was published in the *British Medical Journal* was certainly of interest, for in his opinion, ' If all these infectious diseases are due to morbific germs, I suppose fresh ones might appear, and others depart just as the different blights affecting the vegetable world ' I am, Sir, yours faithfully,

West Drayton June 3rd 1913 ROBERT LEE

RETRACTION RING AND OBSTRUCTION IN LABOUR

To the Editor of THE LANCET

SIR —In the report of my remarks in replying to the criticisms on my paper on the Retraction Ring which appears on p 1532 of THE LANCET of this date, it is stated He would *not* do Cæsarean section ' The *not* should be left out I am, Sir, yours faithfully,

Glasgow May 31st 1913 ROBERT JARDINE

THE CHADWICK PUBLIC LECTURES —These lectures (illustrated by lantern slides) are being given by Dr F W Mott in the lecture room of the Royal Society of Arts John street Adelphi, W C The first lecture is delivered to day, Friday, June 6th The second and third will be given on June 13th and 20th respectively The subject is—Nature and Nurture in Mental Development thus subdivided (*a*) Structure and Development of the Brain , (*b*) Inborn Potentialities of the Brain of the Child , (*c*) Influence of Education and Nutrition Admission is free, and information may be obtained of the secretary, Mrs Aubrey Richardson at the offices of the Trust, 8, Dartmouth street, Westminster

Owing to want of space it is impossible to make adequate provision for our nurses, and most of the bedrooms are shared by two or three The question of the proper housing of the nursing staff was one in which the late Duke took the greatest personal interest, and in the hope of improving matters an appeal was made under his direction which resulted in some £2000 being subscribed towards a new " Home "

A further £10 000 is required to carry out the work, and it is earnestly hoped that sufficient help will be forthcoming to enable the late President s wish to be realised, and at the same time afford an opportunity for the board to associate his name for ever with a work which he had so much at heart

Contributions however small, will be very gratefully received and may be addressed to us at the hospital

We are, Sir, yours faithfully,
ARTHUR HILL
Chairman " Abercorn Memorial
Executive Committee
GEO F MARSHALL
June 3rd 1913 Chairman West London Hospital

PS —Up to the present a total sum of £3200 has been received

THE LATE MR JORDAN LLOYD

To the Editor of THE LANCET

SIR,—It has been decided to commemorate the work of the late Mr Jordan Lloyd by naming one of the surgical wards at Queen's Hospital after him

The medical staff are anxious to appeal, through your courtesy, to members of the profession in Birmingham and the Midlands to aid in the endowment of this ward They feel that those with whom Mr Jordan Lloyd worked for so many years, and many of whom owe so much to him as a teacher, would wish to be associated in contributing to the Memorial Fund

Cheques should be made payable to the Queen s Hospital (Jordan Lloyd Memorial Fund) and forwarded to Mr H F Keep, Queen's Hospital, Birmingham

I am, Sir, yours faithfully
DOUGLAS STANLEY,
Chairman of the Medical Committee
Queen s Hospital Birmingham June 3rd 1913

PROGERIA AND ATELEIOSIS

To the Editor of THE LANCET

SIR,—I should be obliged if you could afford space in THE LANCET for the following communication although it arrives so late upon the scene (Reasons for this will, I think be obvious)

In THE LANCET of Feb 1st of this year was a paper by Professor A Keith upon the subject of progeria and ateleiosis It is obvious in the case of ateleiosis that there is urgent need of post mortem examinations Such cases as that described by Rennie,[1] the condition of the sella turcica in Paltauf s case,[2] and the recent experimental work of the Italian school upon dogs (removal of the pituitary gland in young puppies), indicate that it is to the pituitary body that attention should be directed in the main But all recorded post mortem accounts are silent as to the condition of this structure in the cases examined

I wish to indicate (in case the fact should not be known already) to Mr Hastings Gilford, Professor Keith, and other readers of THE LANCET who are interested in this subject that there are the following cases of this condition (amongst many others) touring about Europe or America in " shows " and to submit that it would be deplorable if any of them were permitted to die without necropsy, *for it would be a* great waste of opportunity I may say that I have myself endeavoured to make arrangements for this to be done, but without any success and I have come to realise that only the great can bring this to pass, and that the efforts in this direction of such as myself will be as they have been, unavailing

There are the following cases of Mr Hastings Gilford s second group 1 The two brothers Magri (Primo and Ernesto—known as " Baron ' Magri) *from Tuscany* These have been described by Veratti Aged about 60 to 65 years It may be presumed that one or other may die before very long 2 The two brothers Heinrich and Bruno Glauer, from Innsbruck, Tyrol Aged about 26 and 22 years 3 Smaun Sing H Poo, from Burma, aged about 26 years He has been described by Virchow (There was another case in this family which died very young) This case is at present in Australia touring in a " freak" show 4 Ludwig Alpts, aged about 20 years, smaller than any of the others His mother, an aunt, and a female cousin are achondroplasic, while his reputed father was ateleiotic 5 A Turkish case of between 50 and 60 years of age, the name of which I forget

MANCHESTER

(FROM OUR OWN CORRESPONDENT)

The University of Manchester

FROM the annual statement of the Vice Chancellor we find that altogether there were 1663 students attending the University during 1912-13, and of these 372 are medical students, including 32 women students Of these, 134 are preparing for degrees of the University, 7 for the University of London, 10 for other universities, 2 for F R C S , 29 for Conjoint Board, 3 for the Triple qualification, 3 for the Diploma in Psychological Medicine, 3 for B D S , 48 for L D S Manch , 15 for L D S Eng , and 41 are working in special departments—viz , medical, 5 , pharmaceutical, 5 , and public health, 31 —In the dental department an arrangement, which has been approved by the Board of Education, has been made with the Manchester Dental Hospital In view of this arrangement the Board now makes a substantial grant in respect of the clinical instruction given in the Dental Hospital to students reading for the degree or diploma in dentistry A substantial sum will thus become available annually for the maintenance and improvement of clinical instruction and for providing facilities for students in the dental department — Some time ago the University formulated a scheme for a Diploma in Ophthalmology somewhat on the lines of the diplomas in this subject in other universities This scheme received the approval of Senate and Council At a meeting of Convocation held on May 23rd this body, by a majority, passed a resolution that "in the opinion of Convocation the institution of a Diploma in Ophthalmology is not to be desired " This resolution was forwarded to the Court which met on May 28th when the question was referred back for further consideration At the same meeting of the Court, Lord Morley presiding, a letter was read from the Vice Chancellor, Sir Alfred Hopkinson, tendering his resignation of the office of Vice Chancellor A unanimous resolution was passed asking the Vice Chancellor to reconsider his decision "in the interests of the University '

Virtues of Gas and Gas Fires Manchester s Smoky Atmosphere

The Manchester and Salford Sanitary Association held its annual meeting last week, when it was reported that a committee had undertaken an inquiry into the question of gas fires and their wholesomeness The results of the inquiry will, it is hoped, lead to the improvement of gas fires, and probably help to promote their extended usefulness An address was given by Mr William Thomson on Gas Fires their Proper Construction, Economic Use and Hygienic Advantages The subject was treated rather from the point of view of the chemist than from that of the engineer Mr Thomson ridiculed the notion that a basin of water placed near a gas fire tended to moisten the atmosphere A strong appeal was made for cheapening the charge for gas, so as to encourage the general use of gas fires A great advantage through the burning of gas in houses and offices would be the keeping of the air of the town purer, thereby obviating the enormous injury caused to decorations and the great cost of washing and cleaning entailed by "the present barbarous method of burning raw coal The speaker mentioned a weaving shed with an area of 11 000 square yards from which was taken 40 tons of sludge this having accumulated in three years and this amount, he contended, was due entirely to the dirty atmosphere of the city Another speaker went further, and stated that every foreigner who came to Manchester spoke of the filthiness of the working class house It is claimed that the gas fires recently placed on the market show a great improvement over the gas fires previously available even four or five years ago, and that they give about 50 per cent of their heat by means of radiation and only about 25 per cent by means of convection the remaining 25 per cent being utilised to ventilate the room and carry off the products of combustion The most hygienic source of heat is the sun The heat rays from such a radiant body do not heat the air through which they pass In this connexion reference may be made to the paper contributed by Professor Leonard Hill and Mr F F Muecke to THE LANCET of May 10th on "Colds in the Head " The heat given out by a modern gas fire causes the nose to be less susceptible to infection than convection heat An all essential point regarding the modern gas fire is that it should be most carefully fixed, so that none of the products of combustion reach the atmosphere of the living room

Lancashire Education Committee s Report on Defects in School Children

Last year, out of 51,356 school children examined by the Lancashire education committee s medical inspectors, no fewer than 24 901 were found to have physical defects The number of children on the roll was 153,711, and the average attendance was 131 584, 5188 being half timers The most common ailments were skin diseases 7369 , enlarged tonsils, 3787 , adenoids, 1570 , while 5339 had very bad teeth The total number of actual eye diseases was 2221, and there were 1121 cases of squint Heart disease was found in 278 diseases of the lungs in 499, rickets in 942, and 418 were under nourished

A Unique Case Double Maternity Benefit under the National Insurance Act

Some weeks ago at Barrow, near Clitheroe, the mother gave birth to a second child five weeks after the first child was born The father made application for maternity benefit in respect of the second child The Commissioners have decided that it was a separate birth thus entitling the parents to the double benefit

Ptomaine Outbreak at Northwich

Between May 30th and June 1st no fewer than 14 persons at Northwich were medically certified to be suffering from ptomaine poisoning, several of the cases being acute and dangerous The outbreak is attributed to pressed beef Samples have been sent to the Public Health Laboratory, Manchester, for analysis

NEWCASTLE-ON-TYNE

(FROM OUR OWN CORRESPONDENT)

Royal Victoria Infirmary Presentations to Dr David Drummond and Sir Thomas Oliver

A quarterly court of governors of this charity was held on May 29th in the infirmary, Sir Riley Lord presiding over a large attendance Apart from pure business the main feature of the meeting was the presentation of illuminated addresses to Dr David Drummond and Sir Thomas Oliver, M D , on the occasion of their retirement from the active staff of the institution the statutory age limit being attained In presenting the address to Dr Drummond Sir Riley Lord *expressed the great regret of the governors* that the time had arrived for his retirement Dr Drummond had been an honorary physician for 34 years, a period which had only been exceeded on one previous occasion, by the late Dr Thomas Emerson Headlam, who was physician for 38 years Dr Drummond s association with the infirmary had been a notable one, distinguished by faithful attention to duty and careful observance of official responsibility By his distinctive ability and diagnostic acumen he had attained to a position of eminence and fame in his profession and as a professor of clinical medicine he had maintained the traditions of the infirmary The address, which Sir Riley Lord then presented to Sir Thomas Oliver, pointed out that the recipient had been a physician on the staff for 33 years and paid a tribute to his high even international, reputation as a scientific physician and a practical physiologist It commented on the effects of his investigations on trade conditions and their relation to the public health, and pointed out the resulting benefactions to the industrial community

Voluntary Hospitals and Workmen s Contributions

At the same quarterly court the following motion in the name of the Chopwell Miners Lodge was considered :—

That employers of labour limited liability companies industrial concerns and business men be asked to contribute to the funds of the of long duration and to obtain anthropogenous antitoxin of high value The preparation is given only under the above conditions and to hospitals where the examinations required can be performed

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Scottish Medical Insurance Council.

THE Scottish Committee of the British Medical Association has withdrawn from the Medical Insurance Council, a step which appears to lead to the dissolution of that Council.

Causes of Abnormally Defective Eyesight at Kilsyth.

Dr. J. B. Stewart, at the request of the Kilsyth burgh school board, has prepared a report on the causes of the abnormal extent of defective eyesight which he found when examining the Kilsyth school children compared with others. He points out that heredity plays an important part in the cause of defective vision. Kilsyth is a mining area and coal mining has a very trying effect on the miners' eyes. If there was any defect present when a young man began his career in the mines it was certainly not improved by his subsequent work there. This going on for several generations accounted in a large measure for the present condition of the eyes of Kilsyth children.

Infant Mortality in Paisley.

The work being done in Paisley by the burgh local authority and private agencies with the view of minimising the mortality of infants under one year of age has been summarised by the medical officer of health for the burgh. Last year the number of infants under one year who died was 209, which gave an infantile mortality rate of 92.15 per 1000 births, being 33 deaths less than the previous year, when the rate was 111.72 per 1000 births. It is only right to point out, however, that there were during the past year exceptional circumstances which conduced to this result. Work was more plentiful, and the conditions which affect very young children in times of unemployment were absent. The medical officer of health in his report drew attention to the question of hospital accommodation for children. In this respect Paisley compares badly with other towns. The Royal Alexandra Infirmary admits young children but these are accommodated along with the adults, and the number of admissions is, in the circumstances, limited. Although for a general hospital the percentage of children is high, in other towns the children's hospital does away with the necessity for many admissions to the general hospital. The local authority during the past year has been in communication with the infirmary directors regarding this matter, but it is understood that the directors for financial reasons are meanwhile unable to do anything further.

Insurance Medical Benefit for Temporary Residents.

At a special meeting of the Aberdeen Borough Health Insurance Committee held on May 30th the clerk read a letter from the Commissioners regarding the provision of medical benefit to temporary residents, with a view to eliciting the views of the committee on the two alternative schemes. The chairman explained these alternatives and the unsatisfactory nature of the present arrangement whereby a person going out of his own insurance district had to give notice to the committee in whose district he was to be temporarily resident. The difficulty of getting insured persons to do so was, he said, very great. A separate memorandum had been issued with regard to fish workers requesting employers to give notice to all the workers who were removing from one district to another in order that special provision might be made for them in regard to medical benefit. The method suggested by the Commissioners was that the doctor should be paid for those workers on a basis of attendance. With regard to the two methods suggested by the Commissioners for the provision of medical benefit to temporary residents, the first—namely, that a central fund be formed on the basis of a case value contribution, which meant that if in Aberdeen each case cost 10*s.* and in Aberdeenshire 6*s.*, if any person from Aberdeen went into the county and required medical attendance the city committee would be charged 10*s.*, and if someone from the county came into the town of Aberdeen and required medical attendance the county committee would be charged 6*s.*—was the one generally preferred by the Medical Committee. Generally speaking, however, the Medical Committee were of opinion that a much better system would have been to have had the central fund contributed by Parliament. There did not seem to be any likelihood of either alternative being generally accepted by the profession; in fact, the medical men in the county had refused to do so. Eventually it was agreed that the scheme could not be brought into operation for the present year, but cognisance was taken of the fact that the local committee had unanimously preferred the case value system.

Insurance Act Grievances in Dundee.

Owing to the fact that there are 95 deposit contributors resident in Dundee who had not a sufficient sum at the credit of their accounts as at Jan. 13th last, to permit of their continuing to receive medical benefit after April 30th, a special committee has been appointed to give consideration to the matter and bring forward recommendations. The clerk to the Dundee Insurance Committee had sent out intimations to the deposit contributors, and a large proportion of these had been returned by the Post Office "Not found." It was remarked at a meeting of the Insurance Committee that some of the persons concerned might not get entry into any Approved Society, and if that sort of thing happened periodically a serious defect in the Act would be revealed.

Insurance Act Difficulty in Orkney.

It was reported at a meeting of the Orkney Insurance Committee held on May 30th that doctors in the herring fishing districts had agreed, on certain conditions, to treat insured persons who had come to the county for the fishing season, but that an answer had not been received from the Insurance Commissioners to communications sent to them on the matter. Certain proposals were made to overcome the difficulty of change of address not being intimated by the fishing population. The only doctor in Stronsay, the chief herring fishing port in Orkney, had intimated that he was willing to give his services if a reasonable capitation grant were accorded, but he would not agree to payment on an attendance basis, on account of the amount of clerical work involved. The matter was left in the hands of the Medical Benefits Committee. It is understood that the position of affairs was made known to the Insurance Commissioners last autumn, but it was only within a week or two of the commencement of the fishing that the local committee was consulted.

June 2nd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Birthday Honours.

KNIGHTHOODS have been conferred on Mr. Andrew J. Horne and Mr. Robert H. Woods. Sir Andrew Horne was President

and is the pres of Medicine in Ireland. Sir Robert the Royal Academy of the Royal College of Surgeons in Woods was President and is at present President of the Ireland from 1910 to 1912, and chairman of the conjoint Irish Medical Association and the British Medical committee of this association. A well known laryngologist he has been Association. President of the British Laryngological Association.

Royal College of Surgeons in Ireland: Election of Officers.

The annual election for the President, Vice-President, Secretary, and Council was held on Monday last and the following were elected for the ensuing year:—President: Mr. Richard D. Purefoy. Vice-President: Mr. F. Conway Dwyer. Secretary: Sir Charles A. Cameron. Council: Mr. William Stoker, Sir Charles A. Cameron, Sir Lambert H. Ormsby, Mr. Henry Gregg Sherlock, Sir Charles B. Ball, Mr. John B. Story, Sir Thomas Myles, Sir John Lentaigne, Sir Arthur Chance, Mr. F. T. Porter Newell, Mr. Shepherd McCormick Boyd, Sir Robert H. Woods, Mr. Richard Lane Joynt, Mr. R. Bolton McCausland, Mr. Edward H. Taylor, Mr. William Taylor, Mr. R. Charles B. Maunsell, Mr. Trevor N. Smith, and Mr. W. Ireland de Courcy Wheeler. The result of the elections to the Council gave rise to some surprise by reason of its omissions.

THE Scottish Committee of the British Medical Association has withdrawn from the Medical Insurance Council, a step which appears to lead to the dissolution of that Council

Causes of Abnormally Defective Eyesight at Kilsyth

Dr J B Stewart, at the request of the Kilsyth burgh school board, has prepared a report on the causes of the abnormal extent of defective eyesight which he found when examining the Kilsyth school children compared with others He points out that heredity plays an important part in the cause of defective vision Kilsyth is a mining area and coal mining has a very trying effect on the miners' eyes If there was any defect present when a young man began his career in the mines it was certainly not improved by his subsequent work there This going on for several generations accounted in a large measure for the present condition of the eyes of Kilsyth children

Infant Mortality in Paisley

The work being done in Paisley by the burgh local authority and private agencies with the view of minimising the mortality of infants under one year of age has been summarised by the medical officer of health for the burgh Last year the number of infants under one year who died was 209, which gave an infantile mortality rate of 92 15 per 1000 births, being 33 deaths less than the previous year, when the rate was 111 72 per 1000 births It is only right to point out, however, that there were during the past year exceptional circumstances which conduced to this result Work was more plentiful, and the conditions which affect very young children in times of unemployment were absent The medical officer of health in his report drew attention to the question of hospital accommodation for children In this respect Paisley compares badly with other towns The Royal Alexandra Infirmary admits young children but these are accommodated along with the adults, and the number of admissions is, in the circumstances limited Although for a general hospital the percentage of children is high, in other towns the children's hospital does away with the necessity for many admissions to the general hospital The local authority during the past year has been in communication with the infirmary directors regarding this matter, but it is understood that the directors for financial reasons are meanwhile unable to do anything further

Insurance Medical Benefit for Temporary Residents

At a special meeting of the Aberdeen Borough Health Insurance Committee held on May 30th the clerk read a letter from the Commissioners regarding the provision of medical benefit to temporary residents, with a view to eliciting the views of the committee on the two alternative schemes The chairman explained these alternatives and the unsatisfactory nature of the present arrangement whereby a person going out of his own insurance district had to give notice to the committee in whose district he was to be temporarily resident The difficulty of getting insured persons to do so was he said, very great A separate memorandum had been issued with regard to fish workers requesting employers to give notice to all the workers who were removing from one district to another in order that special provision might be made for them in regard to medical benefit The method suggested by the Commissioners was that the doctor should be paid for those workers on a basis of attendance With regard to the two methods suggested by the Commissioners for the provision of medical benefit to temporary residents, the first—namely, that a central fund be formed on the basis of a case value contribution, which meant that if in Aberdeen each case cost 10*s* and in Aberdeenshire 6*s*, if any person from Aberdeen went into the county and required medical attendance the city committee would be charged 10*s*, and if someone from the county came into the town of Aberdeen and required medical attendance the county committee would be charged 6*s* —was the one generally preferred by the Medical Committee Generally speaking, however the Medical Committee were of opinion that a much better system would have been to have had the central fund contributed by Parliament There did not seem to be any likelihood of either alternative being generally accepted by the profession, in fact, the medical men in the county had refused to do so Eventually it was agreed that the scheme could not be brought into operation for the present year, but cognisance was taken of the fact that the local committee had unanimously preferred the case value system

Insurance Act Grievances in Dundee

Owing to the fact that there are 95 deposit contributors resident in Dundee who had not a sufficient sum at the credit of their accounts as at Jan 13th last, to permit of their continuing to receive medical benefit after April 30th, a special committee has been appointed to give consideration to the matter and bring forward recommendations The clerk to the Dundee Insurance Committee had sent out intimations to the deposit contributors, and a large proportion of these had been returned by the Post Office "Not found" It was remarked at a meeting of the Insurance Committee that some of the persons concerned might not get entry into any Approved Society, and if that sort of thing happened periodically a serious defect in the Act would be revealed

Insurance Act Difficulty in Orkney

It was reported at a meeting of the Orkney Insurance Committee held on May 30th that doctors in the herring fishing districts had agreed, on certain conditions, to treat insured persons who had come to the county for the fishing season, but that an answer had not been received from the Insurance Commissioners to communications sent to them on the matter Certain proposals were made to overcome the difficulty of change of address not being intimated by the fishing population The only doctor in Stronsay, the chief herring fishing port in Orkney, had intimated that he was willing to give his services if a reasonable capitation grant were accorded, but he would not agree to payment on an attendance basis, on account of the amount of clerical work involved The matter was left in the hands of the Medical Benefits Committee It is understood that the position of affairs was made known to the Insurance Commissioners last autumn, but it was only within a week or two of the commencement of the fishing that the local committee was consulted

June 2nd

IRELAND

(FROM OUR OWN CORRESPONDENTS)

Birthday Honours

KNIGHTHOODS have been conferred on Mr Andrew J Horne and Mr Robert H Woods Sir Andrew Horne was President [illegible] and is the present [illegible] the Royal Academy of Medicine in Ireland Sir Robert Woods was President of the Royal College of Surgeons in Ireland from 1910 to 1912 and is at present President of the Irish Medical Association and chairman of the conjoint committee of this association and the British Medical Association A well known laryngologist he has been President of the British Laryngological Association

Royal College of Surgeons in Ireland Election of Officers

The annual election for the President, Vice President, Secretary, and Council was held on Monday last and the following were elected for the ensuing year —President Mr Richard D Parefoy Vice President Mr F Conway Dwyer Secretary Sir Charles A Cameron Council Mr William Stoker, Sir Charles A Cameron, Sir Lambert H Ormsby Mr Henry Gregg Sherlock, Sir Charles B Ball, Mr John B Story, Sir Thomas Myles Sir John Lentaigne Sir Arthur Chance, Mr F I Porter Newell Mr Shepherd McCormick Boyd, Sir Robert H Woods, Mr Richard Lane Joynt, Mr R Bolton McCausland Mr Edward H. Taylor, Mr William Taylor Mr R Charles B Maunsell, Mr Trevor N Smith, and Mr W Ireland de Courcy Wheeler The result of the elections to the Council gave rise to some surprise by reason of its omissions held in honour of this congress, the Society of Legal Medicine was attended by most of the members of the Congress. The programme included the means of checking the use of narcotic drugs (opium, morphine, cocaine, ether, haschisch) which now constitutes a social danger. Maitre Rocher and M. Régis, M. Vallon, and M. Lacassagne spoke, after which M. Bertillon demonstrated the latest advances in judicial photographometry, and M. Ménard discussed errors of interpretation in radiography.

The Prophylaxis of Gastro-enteritis in Sucklings.

M. Gallois related at the Société de Thérapeutique on May 14th the results of a personal observation. During a very hot summer 12 out of 14 children died on the same day in the crèche of the Hôpital Hérold. Much moved by the waste of life, M. Gallois conceived the idea of having the rooms cooled with large blocks of ice, and this fearful mortality did not recur. Now that this idea has been taken up by other medical men M. Gallois recalled his former experiences.

"*Murderous Measles.*"

If of old time—that is, before the discovery of antidiphtheritic serum—diphtheria was the greatest enemy of children in France, a disease formerly considered benign—viz., measles—replaces it nowadays in fatality, causing at least as many deaths as, if not more than, diphtheria caused before the discovery of antitoxin. Municipal statistics show in Paris about 30 to 40 deaths a week from measles. In the past six weeks the figures have varied between 21 and 45 deaths, the annual rate oscillating about 900. In 1910 there were 860 deaths in children, in 1911 808 deaths from this cause. An inquiry in the Paris hospitals shows that the death toll of measles varies between 15 and 20 per cent. In two hospitals alone—Saint Joseph and the Hôpital Pasteur—the mortality has not risen above 4 or 5 per cent. This marked difference may be due to the fact that cubicular isolation is practised in these two hospitals. The cause of the increased fatality is to be found principally in the fact that the compulsory notification of measles is followed by no prophylactic measures. It is true that disinfection is of little use, for the microbe dies as soon as desiccation is established. But what would be useful is that hygienic precautions should be taken in the schools attended by children with measles. There is no coöperation between the prefecture of police and the sanitary services of the Ministry of the Interior and of the Ministry of Public Instruction. The lycées are even less defended against an epidemic of measles than are the communal schools, in which a medical service is in operation. If in the hospitals measles kills from 15 to 20 per cent. of sick children it is because they are not isolated. Measles is a benign disease, but the secondary complications, especially broncho-pneumonia and diphtheria, which so frequently follow thereon, cause the greater part of the deaths.

Perforating Nasal Ulcers in Gunpowder Factory Workers.

At the Congrès Français d'Otorhinolaryngologie M. Robert Leroux drew attention recently to the perforating nasal ulcer that occurs in powder workers This ulcer is found on the cartilaginous portion of the septum in many workers in powder factories. The author noted two kinds of ulcers—one caused by black powder, composed of saltpetre, carbon, and sulphur; the other by the pyroxyline powder of type J, made of gun-cotton with 17 per cent. of the bichromates of ammonium and potassium. The first acts after the fashion of common powders with carbon and saltpetre—viz., by inflicting microscopic traumatisms, but on a mucosa previously irritated by sulphurous compounds; the other, by the action of the chromates, produces an ulcer through nerve injury. The evolution of the perforating ulcer of powder workers occurs in three stages: the formation of xanthosis, a dirty, yellow state of the mucosa from internal hæmorrhages, formation of an ulcer; and perforation. The perforation due to black powder requires many months for completion, while that due to powder J may be complete in eight days. A few crusts and blood-clots are rarely taken notice of. The perforating ulcer is painless, and must be intentionally looked for. The preventive measures recommended are the wearing of a mask and the limitation of working hours. Treatment lies in neutralising the chromic salts.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

Quinine in Scarlet Fever.

AT the meeting of the Royal Academy of Medical Sciences of Palérmo on April 26th some interesting observations on this subject were brought forward. During the antimalarial campaign of the Croce Rossa in Sicily last autumn there was an epidemic of scarlet fever in the neighbourhood of Marsala. It was observed that the districts under the care of the officers of the Croce Rossa were exempt from this epidemic, though they only differed from the surrounding districts in the fact that their population was under the influence of quinine administered regularly for prophylaxis against malaria In view of the theory of the protozoal origin of the infection of scarlet fever, during another epidemic in the spring of this year at Palermo, a certain number of cases were treated by injections of bichloride of quinine in large doses. The cases were few in number, but for the most part of a certain gravity, and in all of them the injections seemed to cut short the disease. The fever yielded to the second or third injection, desquamation appeared quickly, and the patients were very soon well.

A New Tuberculosis Cure.

Professor Alessandro Bruschettini, of Geneva, presented a communication to the University of Parma in the amphitheatre of the Clinica Medica on May 17th on the subject of a new cure for tuberculosis. This is a so-called "vaccino serum," of which he described the method of preparation. He claims to have obtained such wonderful results in the cure of hundreds of cases of the various forms of tuberculosis that it may be fairly considered a sure and specific cure. He proposes to make an announcement on the subject at the forthcoming International Congress of Medicine in London.

A Professor of Pathology and the Waters of Lourdes.

Professional circles in Genoa have recently been agitated by the publication in the "Journal of the Grotto" of Lourdes of a testimonial written by a member of their University. Dr. Luigi della Valle, professor of surgical pathology in the University of Genoa and surgeon to the hospital, accompanied his wife, whose illness professional skill had failed to cure, to Lourdes last autumn. The effects of the waters corresponded promptly to the lady's hopes and prayers, and in recognition of this her husband was persuaded to sign the following declaration: "I, the undersigned, certify that in the month of September, 1912, my wife, who was seriously ill in consequence of a typhoid infection, complicated by intestinal obstruction, refractory to ordinary therapeutic measures, was in danger of imminent death. She experienced the first symptom of improvement immediately after swallowing a few draughts of the miraculous water of Our Lady of Lourdes, this act of faith being accompanied by the prayers of the patient and of the members of her family. I make this attestation in token of gratitude towards Our Lady of Lourdes." The declaration appears in the *Journal de la Grotte* of May 4th, with the doctor's signature and academic titles, though the doctor had signed it merely as doctor of medicine, and had been under the impression that the declaration would remain private. In Italy, where the antagonism between science and superstition is more bitter possibly than anywhere else in Europe, it is natural that the publication of this document should have aroused much resentment in the scientific circles affected.

May 30th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Vienna Volunteer First-aid Association.

THE First-aid Congress to be held in this city next September has been organised chiefly by the exertions of the well-known Vienna Volunteer First-aid Association, called here the Freiwillige Rettungsgesellschaft, the annual report of which for the year 1912 has just been published. During that year a very great amount of work was accomplished. The number of cases which received attention amounted to held in honour of this congress, the Society of Legal Medicine was attended by most of the members of the Congress. The programme included the means of checking the use of narcotic drugs (opium, morphine, cocaine, ether, haschisch) which now constitutes a social danger. Maître Rocher and M. Régis, M. Vallon, and M. Lacassagne spoke, after which M. Bertillon demonstrated the latest advances in judicial photographometry, and M. Ménard discussed errors of interpretation in radiography.

The Vienna Volunteer First-aid Association.

THE First-aid Congress to be held in this city next September has been organised chiefly by the exertions of the well-known Vienna Volunteer First-aid Association, called here the Freiwillige Rettungsgesellschaft, the annual report of which for the year 1912 has just been published. During that year a very great amount of work was accomplished. The number of cases which received attention amounted to

Sanitary Association and have the necessary approval of the Government of Bombay, who are large contributors to the cost of the new institute Some £1400 is still required if the work of building is to be started free of debt, but the association confidently anticipate that this will speedily be forthcoming, and it is hoped that the foundation stone of the building will be laid by His Excellency the Governor at an early date

Fifty Lakhs for Charity

It is announced in Bombay that a Parsi gentleman, whose name is not disclosed, is arranging to make a charity trust of 50 lakhs of rupees It is stated that he will give effect to his wishes in a short time, and that the administration of the charity will remain under his supervision during his lifetime

The Vicereine and Indian Hospitals

Her Excellency the Lady Hardinge has decided to devote the money that has been placed at her disposal as a thank offering for the Viceroy s recovery to giving an annual treat to children in hospitals on the Viceroy s birthday June 20th will therefore be kept as a "Children's Day" throughout our Indian hospitals Lady Hardinge has also been making a round of the Simla hospitals A few days ago Her Excellency visited the Station Hospital and Station Family Hospital at the important military suburb at Jutogh The Viceregal party were conducted round the hospitals by the senior medical officer, Major R J Blackham, V H S Her Excellency was much interested in what she saw, and promised her assistance in carrying out various projected improvements

Combating Disease in Mysore

The Government of Mysore has just issued an order prohibiting the erection of temporary sheds and huts on Government agricultural land near railway stations with a view to preventing the spread of epidemic diseases, and directing the removal of such sheds or huts on private land where necessary

Rice Cultivation Prohibited

It is notified in the current *Punjab Gazette* that the cultivation of rice crops is prohibited in the neighbourhood of Muzzafagarh, as being injurious to the health of persons dwelling in the neighbourhood, and as being likely to contaminate the water-supply of the municipality

The Sanitation of Madras

Owing to the defective sanitary arrangements in Madras the death rate is said to have been steadily increasing during the last 40 years The existing drainage system consists of open side drains, masonry drains, and pipe drains The open drains are insanitary, the masonry drains are leaky and defective and the pipe drains are inefficient, rendering the whole system a menace to the inhabitants

The Mysteries of Plague

A Bombay newspaper says that one of the mysteries of plague has always been the reason why the incidence of epidemics is so much heavier in some places than in others In the last two years the special point of inquiry has been why the United Provinces should suffer as severely as they do, and particularly so at a time when other parts of India are feeling a general lightening of the burden Madras has always escaped easily One theory put forward regarding Madras was that the mongoose was very prevalent there and kept down the numbers of the plague rat Madras sanitarians, of course, attach much credit to their special passport system of guarding against imported contagion The advisory committee in India have recently published a report of a special inquiry made in Madras on the subject The document may fairly be summed up as saying that Madras has the conditions that go to make a bad plague centre, but that why the ordinary results do not follow is more than the experts can say The inquiry is now to be pursued outside Madras city into various parts of the Presidency, where the same comparative freedom from plague exists but is equally difficult to explain

DONATIONS AND BEQUESTS —The late Mr. Augustine Knocker, of Clifton, left £100 to each of the following institutions Bristol General Hospital, Royal Infirmary, Children's Hospital, Eye Hospital, and Blind an attractive feature for medical men. The Red Cross Society hospital, near the West Kensington entrance, contains much of interest and was very near completion—opposite to it, on a railway siding, was a hospital train, equipped with spring cots (fixe[illegible] accommodation for the staff. [illegible] until the medical portion [illegible] advanced and the various stalls and displays of drill and so forth can be described.

FOURTH INTERNATIONAL CONGRESS ON SCHOOL HYGIENE.—This Congress will be held at Buffalo, U.S A., next August. The organising committee for Great Britain and Ireland is under the presidency of Sir Lauder Brunton. The honorary secretaries are Dr. James Kerr and Mr. E. White Wallis, to whom communications may be addressed at 90, Buckingham Palace-road, London, S W. The Congress will last from August 25th to 30th. It will be under the patronage of the President of the United States, Dr. Woodrow Wilson.

INTERNATIONAL COMMITTEE FOR POST-GRADUATE MEDICAL EDUCATION.—A series of lecture courses on the Progress of Practical Medicine will be given in Berlin by the Lecturers' Association for Medical Vacation Courses from June 19th to 28th, in collaboration with the Central Committee for Medical Post-Graduate Education in Prussia. Foreign practitioners are also entitled to participate. Applications should be sent to the Bureau of the Lecturers' Organisation for Medical Vacation Courses (Mr. H. Melzer, Berlin N.24, Ziegelstr. 10/11). Inquiries will be answered by the Bureau of the Lecturers' Organisation and by the Medical Information Bureau of the Kaiserin Friedrich-Haus (Berlin N.W. 6, Luisenplatz 2-4).

THE RANKING MEMORIAL.—It has been decided that the memorial to Dr. J. E. Ranking, who did so much towards the relief of the sick and suffering poor of Tunbridge Wells, shall take the form of the endowment of a bed in the General Hospital at Tunbridge Wells, in which Dr. Ranking was specially interested and of which he was senior physician. The public appeal for subscriptions to provide some suitable memorial met with such a ready and willing response that a sum of £1273 15*s.* 8*d.* was collected in amounts varying from ¼*d.* to 100 guineas. The sum of £1000 has been set aside for the endowment of the bed, and the balance will be devoted to providing a medallion at the hospital, to be placed over the bed, the sum then remaining to be given to the Samaritan Fund.

CENTRAL MIDWIVES BOARD.—A meeting of the Central Midwives Board was held at Caxton House, Westminster, on May 22nd, with Sir Francis H. Champneys in the chair. A letter was considered from the clerk of the Bedfordshire county council suggesting that the rules should be amended so as to entail an obligation on the midwife to advise medical assistance in any case in which the patient's temperature rises to above 100° F. in the morning on two successive days The Board directed that the clerk of the Bedfordshire county council be informed that his suggestion will be noted for consideration at the next revision of the rules. A letter was considered from the medical officer of health for the county of Durham asking the opinion of the Board as to whether an uncertified person attending a woman in her confinement in company with a registered medical practitioner, and afterwards alone attending the mother for ten days without supervision from the medical practitioner, is guilty of an offence under Section 1 (2) of the Midwives Act, 1902. The Board decided that the medical officer of health for the county of Durham be informed that under the circumstances described by him the uncertified woman appears to have acted as a monthly nurse and not as a midwife. A letter was considered from the clerk of the Hants county council calling the attention of the Board to the system adopted by a midwife approved by the Board for training pupils in sending a pupil to act as her substitute in nursing a patient after her confinement. The Board directed that the clerk of the Hants county council be informed that the Board has carefully considered the facts as stated in his letter, but it does not think that they prove that the midwife did not exercise adequate supervision, nor that the pupil was acting as an uncertified midwife.

NOTES ON CURRENT TOPICS.

Liverpool Corporation Bill.

SEVERAL important clauses rel[illegible] Liverpool Corporation Bill have [illegible] Committee of the House of Com[illegible] of health, gave evidence supporting these provisions. One of the clauses accepted by the committee extended the powers of the officers of the health committee to take samples of food in storage, and another prohibited the sale of inedible fats as foods. A proposal which the committee passed related to the removal of persons suffering from pulmonary tuberculosis to hospital if the lodging or accommodation available for them was such that proper precautions could not be taken to prevent the spread of infection. The removal could only be made on the order of a court of summary jurisdiction, and the clause was to remain in force for three years. Dr. HOPE remarked that its object was to deal with homeless wanderers. Under another clause it was forbidden to bring live rats ashore from ships except for the purposes of examination by the city bacteriologist. This step was taken to safeguard the port from the infection of plague, which rats conveyed. At the suggestion of the Home Office a new clause was submitted prohibiting the keepers of common lodging-houses from receiving persons suffering from trachoma or other contagious disease of the eye. Subject to the report of the Local Government Board the committee intimated that it would accept this proposal.

Amendment of the National Insurance Act.

Details of the Bill which the Government will introduce to amend the National Insurance Act are in the meantime strictly withheld. However, it is stated that the measure will be of wider scope than was contemplated some time ago, and that its discussion is likely to cover three or four Parliamentary weeks.

Petitions of the Royal Sanitary Institute.

Petitions to the House of Commons have been presented by the Royal Sanitary Institute in favour of the Daylight Saving Bill, the Death Registration and Burials Bill, the Elementary Education (Defective and Epileptic Children) Bill, the Mental Deficiency Bill, the Milk and Dairies Bill, and the Milk and Dairies (Scotland) Bill.

Voluntary Contributions under the National Insurance Act.

It is stated by Mr. MASTERMAN that the number of voluntary contributions under the Insurance Act is only 20,500 [illegible]

Notes, Short Comments, and Answers to Correspondents.

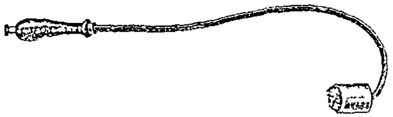
THE PRUSSIAN PANEL DOCTOR.

IN the course of a discussion which has been *going on in the correspondence* columns of the Berlin newspapers on the strained relations existing between the medical profession and the insurance committees, the Prussian Government is said to have in view a proposal for engaging 3000 medical practitioners and thus forming a State Medical Service. It is thought by many, however, that the mention of this scheme is only for the purpose of finding out how far it would meet with general acceptance The present state of things is most disquieting to the authorities.

ELECTRODE FOR NAPE OF NECK.

To the Editor of THE LANCET

SIR,—In these days of ionic medication and the more extensive use of electricity generally, especially of galvanism, the electrode shown below, which I devised many years ago, and which I have used constantly ever since, may be of interest. When it is desired to hold one pole to the nape of the neck, as is often the case when applying electricity to the face, for instance (or to the eyes, *as in my own practice*), the straight handle usually supplied by the makers is not a very convenient tool. By bending the brass rod which carries the applicator (sponge, carbon, or metal plate) into a curve something like a note of interrogation the patient can himself keep the pole at the desired spot without any trouble or fatigue.—I am, Sir, yours faithfully,



A. ST. CLAIR BUXTON, F.R.C.S. Edin.,
Consulting Surgeon to the Western Ophthalmic Hospital.
Weymouth-street, W , May 28th, 1913

THE INTERNATIONAL FEDERATION FOR THE ABOLITION OF STATE REGULATION OF VICE.

To the Editor of THE LANCET.

SIR,—Your attention is very specially directed to the Congress of the International Federation for the Abolition of State Regulation of Vice to be held in Paris at the Musée Sociale, June 8th to 12th.

This Congress ought to be of quite exceptional interest. Paris has for long been the home of the regulation system; both in England and America *to-day a very large number of people believe it would be much* better if "puritanical fanatics" would allow it to be adopted elsewhere. It will be deeply interesting to hear physicians, lawyers, and statesmen exposing in Paris itself the iniquities of this "French system," which is supported, not by public opinion, but by a combination of vested interests and political cowardice and public apathy.

The speakers from this country include Dr. Helen Wilson and Sir Victor Horsley.

Tickets can be obtained from *M. Otto Pierson, 97, Rue de Courcelles*, Paris.

I am, Sir, yours faithfully,
F. M. MCNEILL,
Acting Secretary of the British Committee.
19, Tothill street, Westminster, S.W., June 2nd, 1913.

MALINGERING. AN EXPLANATION.

To the Editor of THE LANCET.

SIR,—In a recent address on "Malingering, Valetudinarianism, and their Prevention," delivered before the Pathological Society of Manchester, and published in the *British Medical Journal* of April 19th, 1913, Dr. Byrom Bramwell referred to some misleading statements which he said had been made at the last meeting of the British Medical Association in the course of discussion on medical *training for the* detection of malingering, with regard to the reaction of degeneration and the electrical testing generally of muscles. In the course of his lecture he said. "In a recently published book on malingering equally erroneous statements as to the effect of electricity in cases of paralysis and of the value of electrical testing in the diagnosis of malingering are made."

I have been in communication with Dr Byrom Bramwell, and I have his authority for stating that his criticisms did not refer to my book on malingering, but to an entirely different work.

I am, Sir, yours faithfully,
JOHN COLLIE.
Porchester-terrace, W. May 28th, 1913

nt House Surgeon.
d washing.
House Surgeon for
m, with board and
residence. Also Clinical Assistants.

ROYAL FREE HOSPITAL, Gray's Inn road, W.C.—Female Assistant to
t Anæsthetist. Salary

r, City-road, London.
ths. Salary at rate of

Births, Marriages, and Deaths.

BIRTHS.

MACNAUGHTON-JONES.—On May 30th, at Fontenoy, Finchley-road, N.W., to Dr. and Mrs. Macnaughton-Jones, a son.

ford, Chantry-lane, Grimsby, to
, a daughter.
the wife of William Lochhead
Scott, M.D., of a son.

MARRIAGES.

Parish Church, by the

and Lady Whittaker.

NEEDHAM—NEWMAN.—On May 31st, at St. George's Church, Campden Hill, Frederick Needham, M.D., to Helen Millicent Sherwood Newman, daughter of the late William L. Newman, of York.

DEATHS.

TARGETT.—On May 26th, James Henry Targett, Senior Obstetric Physician to Guy's Hospital, in his 51st year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

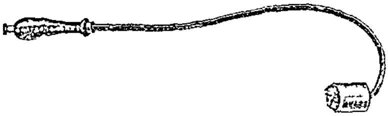
THE PRUSSIAN PANEL DOCTOR.

IN the course of a discussion which has been going on in the correspondence columns of the Berlin newspapers on the strained relations existing between the medical profession and the insurance committees, the Prussian Government is said to have in view a proposal for engaging 3000 medical practitioners and thus forming a State Medical Service. It is thought by many, however, that the mention of this scheme is only for the purpose of finding out how far it would meet with general acceptance The present state of things is most disquieting to the authorities.

ELECTRODE FOR NAPE OF NECK.

To the Editor of THE LANCET

SIR,—In these days of ionic medication and the more extensive use of electricity generally, especially of galvanism, the electrode shown below, which I devised many years ago, and which I have used constantly ever since, may be of interest. When it is desired to hold one pole to the nape of the neck, as is often the case when applying electricity to the face, for instance (or to the eyes, as in my own practice), the straight handle usually supplied by the makers is not a very convenient tool. By bending the brass rod which carries the applicator (sponge, carbon, or metal plate) into a curve something like a note of interrogation the patient can himself keep the pole at the desired spot without any trouble or fatigue.—I am, Sir, yours faithfully,



A. ST. CLAIR BUXTON, F.R.C.S. Edin.,
Consulting Surgeon to the Western Ophthalmic Hospital.
Weymouth-street, W., May 28th, 1913

THE INTERNATIONAL FEDERATION FOR THE ABOLITION OF STATE REGULATION OF VICE.

To the Editor of THE LANCET.

SIR,—Your attention is very specially directed to the Congress of the International Federation for the Abolition of State Regulation of Vice to be held in Paris at the Musée Sociale, June 8th to 12th.

This Congress ought to be of quite exceptional interest. Paris has for long been the home of the regulation system; both in England and America to-day a very large number of people believe it would be much better if "puritanical fanatics" would allow it to be adopted elsewhere. It will be deeply interesting to hear physicians, lawyers, and statesmen exposing in Paris itself the iniquities of this "French system," which is supported, not by public opinion, but by a combination of vested interests and political cowardice and public apathy.

The speakers from this country include Dr. Helen Wilson and Sir Victor Horsley.

Tickets can be obtained from *M. Otto Pierson, 97, Rue de Courcelles,* Paris.

I am, Sir, yours faithfully,
F. M. MCNEILL,
Acting Secretary of the British Committee.
19, Tothill street, Westminster, S.W., June 2nd, 1913.

MALINGERING. AN EXPLANATION.

To the Editor of THE LANCET.

SIR,—In a recent address on "Malingering, Valetudinarianism, and their Prevention," delivered before the Pathological Society of Manchester, and published in the *British Medical Journal* of April 19th, 1913, Dr. Byrom Bramwell referred to some misleading statements which he said had been made at the last meeting of the British Medical Association in the course of discussion on medical training for the detection of malingering, with regard to the reaction of degeneration and the electrical testing generally of muscles. In the course of his lecture he said. "In a recently published book on malingering equally erroneous statements as to the effect of electricity in cases of paralysis and of the value of electrical testing in the diagnosis of malingering are made."

I have been in communication with Dr Byrom Bramwell, and I have his authority for stating that his criticisms did not refer to my book on malingering, but to an entirely different work.

I am, Sir, yours faithfully,
JOHN COLLIE.
Porchester-terrace, W. May 28th, 1913

ANCOATS HOSPITAL, Manchester.

THURSDAY.—4.15 P.M., Mr. W. H. Hey: Surgical Cases for Diagnosis. (Post-Graduate Clinic.)

ROTUNDA HOSPITAL POST-GRADUATE COURSES, Dublin.

MONDAY.—10 A.M., Obstetrical Lecture: Obstetrical Diagnosis (continued). 11 A.M., Examination of Patients and Minor [illegible] 4 P.M., Class in Gynæco- [illegible] ture. Pelvimetry. 11 A.M., Operations.

FRI[illegible] Uterine Displacements. [illegible] d Minor Operations. [illegible]

For further particulars of the above Lectures, &c., see Advertisement Pages.

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced:—

April 26th-Nov. 5th (Ghent).—International Exhibition.
May 22nd-June 7th (London, Olympia).—Royal Naval and Military Tournament.
„ 31st to October (London, Earl's Court).—Imperial Services Exhibition.
May-October (Leipzig).—First International Building Exhibition.
June 11th (open) (London, Crystal Palace).—Anglo-German Exhibition.
„ 16th and 17th (Minneapolis).—Fifteenth Annual Meeting of the American Proctologic Society.
„ [illegible]
„ [illegible] (Or- [illegible]
„ [illegible] tion.
„ 26th-28th (Oxford).—Fourth Annual Conference of the British Hospitals Association.
„ 27th (L[illegible] Pure [illegible]
„ 30th a[illegible] Diet, [illegible] and [illegible] Institutions.
July [illegible] Congress of the Royal [illegible]
„ [illegible]) —Oxford Ophthalmo- [illegible]
„ [illegible] Transport Conference.
„ 21st-24th (London).—British Pharmaceutical Conference.
„ 22nd-25th (Brighton).—Eighty-first Annual Meeting of the British Medical Association.
Aug. 1st-3rd (Ghent).—Congress against the Adulteration and [illegible]
„ [illegible]
„ [illegible]
„ 4th and 5th (London, Caxton Hall).—English-speaking Conference on Infant Mortality.
„ 6th-12th.—(London).—Seventeenth International Congress of Medicine.
„ 20th-26th (Ghent).—Third International Congress of Neurology and Psychiatry.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that *only those subscriptions* which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 6 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—MESSRS. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

ABSTRACT OF

A Lecture

ON THE

RELATION OF SO-CALLED "INFLUENZA" TO BRONCHITIS AND TUBERCULOSIS.

Delivered at the Medical Graduates' College and Polyclinic on May 26th, 1913,

By A. J. JEX-BLAKE, M.A., M.B., B.Ch. Oxon., F.R.C.P. Lond.,
ASSISTANT PHYSICIAN TO ST. GEORGE'S HOSPITAL AND TO THE HOSPITAL FOR CONSUMPTION, BROMPTON.

In the out-patient department of the Brompton Hospital for Consumption one is often struck by the frequency with which the patients volunteer a history of having had one or more attacks of what they call "influenza." They are, of course, using the term in a purely popularly clinical sense, and without attaching any strict scientific meaning to it, much less any bacteriological interpretation. So far as I can understand, a patient who tells you he has had "influenza" merely implies that he has had a particularly severe and acute cold, cough, or sore-throat; with such signs and symptoms as running at the eyes, severe headache, pains in the back and limbs, loss of appetite, sleeplessness, and almost always with a deal of muscular weakness and prostration during the attack. All these are symptoms highly characteristic of the attacks of true influenza, and were habitually met with in the epidemics of influenza that raged through Europe 20 years ago and more—from 1889 to 1893. Hence there is no doubt that from the clinical point of view the patient who has these symptoms and diagnoses his case as one of influenza is not without some practical justification. But one would like to know how far such a patient is correct in his diagnosis from a medical point of view. Accordingly during the last three or four years I have been making inquiries into the past histories of out-patients at the Brompton Hospital to see if they would throw any light on the meaning of the word "influenza" as ordinary people like the patients use it. I think I shall be able to show you that in a great many cases an attack of "influenza" means an attack of acute bronchitis due to infection with some microbe other than the Bacillus influenzæ, and that in many more "influenza" really means an acute tuberculous infection of the lungs. It appears to be unlikely that more than a few of these attacks of "influenza" are caused by the Bacillus influenzæ, or are to be spoken of as influenzal from the bacteriological point of view.

Diagnosis of Influenza.

Before going further it would perhaps be as well to attempt some definition of what does constitute and is diagnostic in an attack of real influenza. One might think that this would be an easy thing to do, but it is not; for there seem to be no definite criteria by which influenza can be either diagnosed or excluded infallibly. As regards its diagnosis, that may be attempted on three separate lines—the epidemic, the bacteriological, and the clinical; and it is best to consider these three lines of diagnosis separately. Whenever, as has often happened in the past and as still happens occasionally, influenza occurs in *epidemics* and the influenza bacillus can be demonstrated in the discharges from the patients' noses, throats, or bronchi, the diagnosis is easy and obvious, because it [illegible] is an epidemic disease, [illegible] presenting a great va[illegible] certain features in common. The chief of these are a sudden onset, great prostration and weakness, irregular fever, and catarrh of some part of the respiratory tract. The result is that when influenza is about in epidemic form experience proves that it can be diagnosed satisfactorily on clinical grounds in most cases, and without having recourse to the bacteriological examination of the discharges from the patients' noses or bronchi, or of swabs taken from their throats. But when one comes to the diagnosis of influenza occurring sporadically, of influenza that is endemic and not epidemic, the case is quite different, for here the epidemic character of influenza, that is recognised as so important from the diagnostic point of view, is absent. Hence the diagnosis must here be made on bacteriological and clinical grounds; and, unfortunately, the ground in both these [illegible] influenza first. The Bacillus [illegible] be the cause of influenza by Pfeiffer in 1892, towards the end of the very severe and widespread pandemic of influenza that went on from 1889 to 1893. This bacillus was universally recognised as the cause of influenza in that pandemic, and also in a succession of smaller epidemics that continued to occur at intervals in England and Europe during the last years of the nineteenth century. But during the last 10 or 12 years only a few small epidemics of influenza [illegible] Kolle and Hetsch, the [illegible] in many countries, so [illegible] on the closeness and the necessity of its connexion with what the clinician terms influenza. Again, sporadic attacks of influenza with an exact clinical resemblance to the attacks of influenza seen in the epidemics of 20 years ago still occur, but often without the presence of Pfeiffer's bacillus. For example, Jochmann examined 36 sporadic cases of influenza in 1904–05 and could find Pfeiffer's bacillus present in only 13 of them. In the same way Ruhemann in 1905 could find the bacillus influenzæ in only 36 out of 73 cases diagnosed clinically as influenza.

The endemic form of influenza, therefore, seems to differ from the epidemic form in two important particulars; in the first place, it is sporadic, and therefore far less contagious than the epidemic form; and in the second place, it is associated with Pfeiffer's bacillus in perhaps less than half the cases, so that it has been held that other microbes may be the infecting agents in sporadic influenza. Baumgarten indicates the differences between epidemic and sporadic influenza by comparing them to epidemic (Asiatic) cholera and cholera nostras respectively. Hence it may be argued, from the clinical and from the bacteriological points of view, that the absence of Pfeiffer's bacillus does not disprove the diagnosis of influenza.

The next diagnostic difficulty is this—that the influenza bacillus may be present for years in the sputa of patients who have had influenza, but who no longer show any symptoms of the disease and also are not sources of infection for other people. Thus, Lord, of Boston, in 1902 reported 18 chronic cases of influenzal bronchitis, in which the abundant and purulent sputum continued to contain the bacillus of influenza, and in 8 the same microbe was present in almost pure culture two and a half years later. Wohlwill made bacteriological examinations of the contents of phthisical cavities in 73 cases post mortem, and isolated Pfeiffer's bacillus from 16 of them; in 9 it was present in pure culture. Hence it is argued that in certain cases the presence of the Bacillus influenzæ in a patient's sputum does not necessarily prove that he is suffering from influenza; the [illegible]tum simply as a saprophyte. [illegible] in 1893, "Wo Influenza- [illegible]iven up entirely.

A third and final difficulty in the bacteriological diagnosis of influenza lies in the fact that there are a number of different bacilli that very closely resemble Pfeiffer's Bacillus influenzæ [illegible] reactions. [illegible] species of [illegible] method of inoculation is not possible. Influenza-like bacilli (B. pseudoinfluenzæ, B. influenzæ similis) have been found as saprophytes or epiphytes in putrefying protein, in decomposing human sputa, in the pulmonary cavities of patients with tuberculosis, in bronchiectasis, in the pus of middle-ear disease; Jochmann has found an identical microbe, which he calls the Bacillus pertussis, almost constantly in whooping-cough, and he has isolated identical microbes from the sputa or throat-swabs of children with measles, scarlet fever, and chicken-pox. In all these cases one may explain away the presence of influenza bacilli in two ways. Either one may say that the bacilli are not true influenza bacilli, but only closely resemble them; or one may say that they are true Pfeiffer's bacilli, but are present as harmless and non-pathogenic saprophytes (Matthes). At any rate, you will see clearly that the bacteriological diagnosis of influenza, which used to be so simple in the days

ABSTRACT OF

A Lecture

ON THE

RELATION OF SO-CALLED "INFLUENZA" TO BRONCHITIS AND TUBERCULOSIS.

Delivered at the Medical Graduates' College and Polyclinic on May 26th, 1913,

BY A. J. JEX-BLAKE, M.A., M.B., B.CH. OXON., F.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO ST. GEORGE'S HOSPITAL AND TO THE HOSPITAL FOR CONSUMPTION, BROMPTON.

IN the out-patient department of the Brompton Hospital for Consumption one is often struck by the frequency with which the patients volunteer a history of having had one or more attacks of what they call "influenza." They are, of course, using the term in a purely popularly clinical sense, and without attaching any strict scientific meaning to it, much less any bacteriological interpretation. So far as I can understand, a patient who tells you he has had "influenza" merely implies that he has had a particularly severe and acute cold, cough, or sore-throat; with such signs and symptoms as running at the eyes, severe headache, pains in the back and limbs, loss of appetite, sleeplessness, and almost always with a deal of muscular weakness and prostration during the attack. All these are symptoms highly characteristic of the attacks of true influenza, and were habitually met with in the epidemics of influenza that raged through Europe 20 years ago and more—from 1889 to 1893. Hence there is no doubt that from the clinical point of view the patient who has these symptoms and diagnoses his case as one of influenza is not without some practical justification. But one would like to know how far such a patient is correct in his diagnosis from a medical point of view. Accordingly during the last three or four years I have been making inquiries into the past histories of out-patients at the Brompton Hospital to see if they would throw any light on the meaning of the word "influenza" as ordinary people like the patients use it. I think I shall be able to show you that in a great many cases an attack of "influenza" means an attack of acute bronchitis due to infection with some microbe other than the *Bacillus influenzæ*, and that in many more "influenza" really means an acute tuberculous infection of the lungs. It appears to be unlikely that more than a few of these attacks of "influenza" are caused by the Bacillus influenzæ, or are to be spoken of as influenzal from the bacteriological point of view.

DIAGNOSIS OF INFLUENZA.

Before going further it would perhaps be as well to attempt some definition of what does constitute and is diagnostic in an attack of real influenza. One might think that this would be an easy thing to do, but it is not; for there seem to be no definite criteria by which influenza can be either diagnosed or excluded infallibly. As regards its diagnosis, that may be attempted on three separate lines—the epidemic, the bacteriological, and the clinical; and it is best to consider these three lines of diagnosis separately. Whenever, as has often happened in the past and as still happens occasionally, influenza occurs in *epidemics* and the influenza bacillus can be demonstrated in the discharges from the patients' noses, throats, or bronchi, the diagnosis is easy and obvious, because it [illegible] is an epidemic disease, [illegible] presenting a great va[illegible] certain features in common. The chief of these are a sudden onset, great prostration and weakness, irregular fever, and catarrh of some part of the respiratory tract. The result is that when influenza is about in epidemic form experience proves that it can be diagnosed satisfactorily on clinical grounds in most cases, and without having recourse to the bacteriological examination of the discharges from the patients' noses or bronchi, or of swabs taken from their throats. But when one comes to the diagnosis of influenza occurring sporadically, of influenza that is endemic and not epidemic, the case is quite different, for here the epidemic character of influenza, that is recognised as so important from the diagnostic point of view, is absent. Hence the diagnosis must here be made on bacteriological and clinical grounds; and, unfortunately, the ground in both these [illegible] influenza first. The Bacillus [illegible] be the cause of influenza by Pfeiffer in 1892, towards the end of the very severe and widespread pandemic of influenza that went on from 1889 to 1893. This bacillus was universally recognised as the cause of influenza in that pandemic, and also in a succession of smaller epidemics that continued to occur at intervals in England and Europe during the last years of the nineteenth century. But during the last 10 or 12 years only a few small epidemics of influenza [illegible] Kolle and Hetsch, the [illegible] in many countries, so [illegible] on the closeness and the necessity of its connexion with what the clinician terms influenza. Again, sporadic attacks of influenza with an exact clinical resemblance to the attacks of influenza seen in the epidemics of 20 years ago still occur, but often without the presence of Pfeiffer's bacillus. For example, Jochmann examined 36 sporadic cases of influenza in 1904–05 and could find Pfeiffer's bacillus present in only 13 of them. In the same way Ruhemann in 1905 could find the bacillus influenzæ in only 36 out of 73 cases diagnosed clinically as influenza.

The endemic form of influenza, therefore, seems to differ from the epidemic form in two important particulars; in the first place, it is sporadic, and therefore far less contagious than the epidemic form; and in the second place, it is associated with Pfeiffer's bacillus in perhaps less than half the cases, so that it has been held that other microbes may be the infecting agents in sporadic influenza. Baumgarten indicates the differences between epidemic and sporadic influenza by comparing them to epidemic (Asiatic) cholera and cholera nostras respectively. Hence it may be argued, from the clinical and from the bacteriological points of view, that the absence of Pfeiffer's bacillus does not disprove the diagnosis of influenza.

The next diagnostic difficulty is this—that the influenza bacillus may be present for years in the sputa of patients who have had influenza, but who no longer show any symptoms of the disease and also are not sources of infection for other people. Thus, Lord, of Boston, in 1902 reported 18 chronic cases of influenzal bronchitis, in which the abundant and purulent sputum continued to contain the bacillus of influenza, and in 8 the same microbe was present in almost pure culture two and a half years later. Wohlwill made bacteriological examinations of the contents of phthisical cavities in 73 cases post mortem, and isolated Pfeiffer's bacillus from 16 of them; in 9 it was present in pure culture. Hence it is argued that in certain cases the presence of the *Bacillus influenzæ* in a patient's sputum does not necessarily prove that he is suffering from influenza; the [illegible]tum simply as a saprophyte. [illegible] in 1893, "Wo Influenza- [illegible]iven up entirely.

A third and final difficulty in the bacteriological diagnosis of influenza lies in the fact that there are a number of different bacilli that very closely resemble Pfeiffer's Bacillus influenzæ [illegible] reactions. [illegible] species of [illegible] method of inoculation is not possible. Influenza-like bacilli (B. pseudoinfluenzæ, B. influenzæ similis) have been found as saprophytes or epiphytes in putrefying protein, in decomposing human sputa, in the pulmonary cavities of patients with tuberculosis, in bronchiectasis, in the pus of middle-ear disease; Jochmann has found an identical microbe, which he calls the Bacillus pertussis, almost constantly in whooping-cough, and he has isolated identical microbes from the sputa or throat-swabs of children with measles, scarlet fever, and chicken-pox. In all these cases one may explain away the presence of influenza bacilli in two ways. Either one may say that the bacilli are not true influenza bacilli, but only closely resemble them; or one may say that they are true Pfeiffer's bacilli, but are present as harmless and non-pathogenic saprophytes (Matthes). At any rate, you will see clearly that the bacteriological diagnosis of influenza, which used to be so simple in the days

1893, when epidemics of true influenza were rampant in England and abroad, no doubt the patient's "influenza" was true influenza. I find that only 30 out of the 661 patients dated their attacks between these years. It should be noted to the credit of the truthfulness of my out-patients that not one of them dated an attack of "influenza" before the year 1889; this is as it should be, for our previous great epidemic of influenza seems to have occurred as long ago as 1847-48. There are, then, historical reasons for supposing that 30 out of the 661 patients who had had "influenza" had been attacked by *the real thing*—true influenza. They all occurred in the 397 cases of Group II. What of the remaining 631? Reference to the table will show that in a good many more the diagnosis of acute pulmonary tuberculosis should have been made.

Group I.

The 112 patients of Series (1) came to the hospital with pulmonary tuberculosis that they dated from a definite attack of "influenza"; the attack occurred two years previously, or less, in 98 instances, and from two to seven years previously in the remaining 14. There can be no doubt, to my mind, that in the majority of these 112 persons the microbe responsible for the initial attack of "influenza" was the Bacillus tuberculosis, and the illness itself acute tuberculosis of the lungs and not influenza at all. I do not overlook the connexion that exists between influenza and tuberculosis, and the fact that the mortality due to phthisis increases during an epidemic of influenza and is lowered afterwards. It is very generally stated and believed that influenza predisposes to tuberculosis of the lungs; but I think that the figures shown in Series (1), (2), and (3) make it more reasonable to suppose that, as things actually are, influenza often *is* tuberculosis, rather than that influenza *predisposes to it*.

To consider next the cases in Series (2). This contains 122 patients who said they had had one or several attacks of "influenza" at a time subsequent to the probable onset of their pulmonary tuberculosis. The weak point of these statistics is, of course, the fact that they depend so largely on the word and memory of the patients, and not on facts observed and properly recorded at the time of their occurrence. In only a few instances did these intercurrent attacks of "influenza" occur while the patient was under my own observation, and then they were so severe that the patient was too ill to make the journey up to hospital and be examined. Hence it is not possible for me to say what new physical signs they developed during the "influenza." But if one may argue from analogous cases that one sees among tuberculous in-patients, one would expect to find that the "influenza" was associated either with a superadded attack of general bronchitis and the development of adventitious sounds all over the lungs and an increase in the sputum, or with physical signs indicating a sudden spread of the tuberculous disease in the lungs. In either case the patient becomes feverish, or more feverish than he was before, suffers from headache and pains all over as he is apt to do in any acute infection of the respiratory tract, feels much prostrated, and diagnoses his case as one of "influenza."

In Series (3) are the cases that may belong properly to either Series (1) or Series (2), but in which the facts available were insufficient to decide where to place them. In each of these Series (2) and (3) occur a certain number of patients, perhaps a sixth part of them all, who had bronchitis or bronchitis with emphysema, as well as tuberculosis of the lungs.

Undoubtedly, as I have already said, the bacterial cause of the "influenza" in these 416 tuberculous patients would generally be the Bacillus tuberculosis. But it must be remembered that this bacillus is not by any means the only one commonly present in the sputum of phthisical patients. This is shown in the following extract from Inman's work of 1911. Inman prepared cultures from the sputa of 101 patients with open pulmonary tuberculosis, and recovered the following bacteria from them: the Bacillus tuberculosis in all the 101 cases, the pneumococcus in 88, Micrococcus catarrhalis in 19, a staphylococcus in 16, Friedländer's bacillus in 6 and a streptococcus in 6. It is clear, therefore, that the tubercle bacillus is not the only one that may be responsible for attacks of "influenza" in phthisical patients.

Out of 416 patients with pulmonary tuberculosis who answered inquiries as to "influenza" only 152 had never had it. These cases are shown in Series (4), and the extent of their pulmonary disease is roughly indicated by their division into three classes—early cases, advanced, and very far advanced. Now if it is true, as I have been suggesting, that many cases of "influenza" are really instances of acute tuberculous infection or re-infection, it is clear that the longer a case of pulmonary tuberculosis goes on the more likely is it to develop [illegible] be the case that the 31 [illegible] (4) should turn out to [illegible] short duration of the l[illegible] fact, most of them are. One patient had been ill for five years, two for three, one for two years; the remaining 27 averaged only eight months apiece from the first symptom of their pulmonary tuberculosis to the day when they told me they had never had "influenza."

So much for the patients with pulmonary tuberculosis, who account for 264 out of the 661 instances of "influenza" in my statistics. About 46 of them had chronic bronchitis, usually with emphysema, as well as the pulmonary tuberculosis. For the sake of simplicity I have included these mixed cases with those of tuberculosis.

Group II.

The second group of patients who gave histories of "influenza" is tabulated in Series (5) to (10), and all of these are non-tuberculous cases so far as the opportunities for diagnosis in out-patients have permitted me to discover.

The frequency with which both chronic bronchitis and chronic bronchitis with emphysema are associated with histories of "influenza" is very conspicuous. In Series (5), (6), and (10) are comprised 613 patients with chronic bronchitis, and no less than 368 of these have had one or more attacks of "influenza." It is among these patients that the recurrence of attacks of "influenza" is most marked; many of them tell one that they have had it every winter for the last five or ten years, or that they have had it half a dozen times in the last 10 or 12 years, as the case may be. As a rule, these influenzal attacks come on in the winter; but in a few instances the "influenza" has been said to occur in the summer, and this has been in the cases in which the "influenza" appeared to me to be hay fever, and to be brought on by exposure to the pollen or dust of the summer months. But how is one to diagnose the actual cause of the attack in the majority of these cases of "influenza" in the bronchitic and emphysematous? Are there any particular microbes to which, in default of the *Bacillus influenzæ*, they can be fairly attributed? These are questions that the material at my disposal does not enable me to answer; but some indication of the frequency with which various bacteria are to be found in the sputa of patients such as these is given by the results of Inman's examination of the sputa of 16 patients with chronic bronchitis in 1911. He found the pneumococcus in all 16 cases, Friedländer's bacillus in 6, the Micrococcus catarrhalis in 3, a staphylococcus in 1. In the sputa of 15 patients with bronchiectasis he similarly found the pneumococcus in 11, Micrococcus catarrhalis in 4, a streptococcus in 4, Friedländer's bacillus in 2, and a staphylococcus in 2. It would, therefore, seem probable that the attacks of "influenza" in these patients were really attacks of acute bronchitis set up by an acute infection with one or more of these various bacteria, but not by the Bacillus influenzæ. It appears that on the Continent and in the United States of America this bacillus is by no means so rare as it would seem to be in London at the present day; in other countries it may often be the cause of bronchopneumonia and of chronic bronchitis (Brückner and others.)

In Series (7) are three patients with extensive fibrosis of one lung that appears not to be tuberculous in origin. In each case the pulmonary disease was said to originate with "influenza." I have notes of ten cases of pleural effusion in patients coming up to hospital with a complaint of "influenza"—nothing being volunteered on the subject of pain in the side or pleurisy—and I think it very likely that pleurisy, with or without effusion, followed by the establishment of pleural adhesions and slow consequent pulmonary fibrosis, should have been the diagnosis in these three cases of "influenza."

In Series (8) are seven instances of morbus cordis in which complaint of attacks of "influenza" was made. The patients, three men and four women, all had mitral disease of long standing; I think it likely that their "influenza" was in reality a non-influenzal bronchitis in each case. The

1893, when epidemics of true influenza were rampant in England and abroad, no doubt the patient's "influenza" was true influenza. I find that only 30 out of the 661 patients *dated their attacks* between these years. It should be noted *to the credit of the truthfulness of* my out-patients that not one of them dated an attack of "influenza" before the year 1889; this is as it should be, for our previous great epidemic of influenza seems to have occurred as long ago as 1847-48. There are, then, historical reasons for supposing that 30 out of the 661 patients who had had "influenza" had been attacked by *the real thing*—true influenza. But how is one to diagnose the actual cause of the attack in the majority of these cases of "influenza" in the bronchitic and emphysematous? Are there any particular microbes *to which, in default of the Bacillus influenzæ*, they can be fairly attributed? These are questions that the material at my disposal does not enable me to answer; but *some indication of the frequency* with which various bacteria are to be found in the sputa of patients such as these is given by the results of Inman's examination of the sputa of 16 patients with chronic bronchitis in 1911. He found the *pneumococcus* in all 16 *cases*, Friedländer's bacillus *in* 6, the Micrococcus catarrhalis in 3, a staphylococcus in 1. In the sputa of 15 patients with bronchiectasis he similarly found the pneumococcus in 11, Micrococcus catarrhalis in 4, a streptococcus in 4, Friedländer's bacillus in 2, and a staphylococcus in 2. It would, therefore, seem probable that the attacks of "influenza" in these patients were really attacks of acute bronchitis set up by an acute infection with one or more of these various bacteria, but not by the Bacillus influenzæ. It appears that on the Continent and in the United States of America this bacillus is by no means so *rare as it would seem to be in London at the present day;* in other countries it may often be the cause of broncho-pneumonia and of chronic bronchitis (Brückner and others)

In Series (7) are three patients with extensive fibrosis of *one lung that appears not to be tuberculous in origin.* In each case the pulmonary disease was said to originate with "influenza" I have notes of ten cases of pleural effusion in patients coming up to hospital with a complaint of "influenza"—nothing being *volunteered on the subject of* pain in the side or pleurisy—and I think it very likely that pleurisy, with or without effusion, followed by the establishment of pleural *adhesions* and *slow consequent* pulmonary fibrosis, should have been the diagnosis in these *three cases* of "influenza."

In Series (8) are seven instances of morbus cordis in which complaint of attacks of "influenza" was made. The patients, three men and four women, all had mitral disease of long standing; I think it likely that their "influenza" was in reality a non-influenzal bronchitis in each case. The

the nature of gout, and of what should and should not be suitable foods for those who suffer from its attacks There can be little doubt that in their main features the current tenets as to the dietetic treatment of gout rest upon a sound basis, but many details of advice which are given could with difficulty be defended in argument How insecure is the footing of many of them is shown by their great diversity. Hardly an article of diet can be mentioned which someone will not be found to forbid

In the dietetic, as in so many other fields, "a little knowledge is a dangerous thing" Our endeavours to help the sufferers from this or that malady by advising them what they should eat, drink, and avoid, may hinder rather than help unless we go very cautiously The conspicuous symptoms are not always the most important, and we sometimes mistake for morbid symptoms Nature's efforts to counteract the processes of disease For example how much harm may be done to sufferers from diabetes if attention be concentrated upon their glycosuria to the neglect of the attendant derangement of metabolism which gives rise to acetonæmia and acidosis. I would even venture to express a doubt whether the painstaking efforts of generations of medical men to devise a suitable dietary for their gouty patients, mainly by elimination of articles of diet some of which are possessed of high nutrient value, have not on the whole done more harm than good, and this not so much to the gouty as to sufferers from other chronic diseases of joints, mostly of bacterial origin These are often subjected to similar dietetic restrictions which for them are undesirable or actually harmful Perhaps this is more often the case in my own country, where gout is so prevalent in all classes of the community, a
has acquired a fixed idea that,
the joints, a restricted dietary
treatment

In spite of the warnings of many recent writers, and of the complete *bouleversement* which our notions about articular maladies are undergoing, it seems well nigh impossible to eradicate this so tenaciously held superstition It had its origin at a time when little progress had been made in the differentiation of such diseases, and although the dividing line between gouty arthritis and arthritis of other natures is becoming fairly well defined we are still far from being able to mark out the boundaries of gout Eczema, lumbago, and sciatica form, with the joint troubles, a sufficiently definite symptom complex, but symptoms are freely labelled as gouty, by profession and public alike which can hardly lay claim to a place in this clinical picture, and of which the relationships to true gout are at best very shadowy These include lesions of the teeth, throat, eyes, and many other organs—indeed, a host of morbid symptoms which are apt to manifest themselves in the middle aged and elderly as products of the wear and tear of life

The members of one school among us, of which Dr A Haig is the protagonist, would extend the connotation of gout to include a large proportion of the ills of humanity, regard uric acid as the underlying cause of all the morbid states included, and a purin free diet as the sovereign preventive of them I would range myself with those who take a much narrower view of the range of gout, and would restrict the name to morbid conditions which stand in an obvious clinical relationship to genuine podagra Even if we confine our ideas of gout within such narrow limits we still find ourselves confronted by two more or less distinct therapeutic problems—namely, How best to avert the development of the gouty state, and how to control the active

long periods, yet he who develops an acute attack in his great toe once a year, or once in two years, has latent gout in the intervals, and does not develop the malady afresh with each attack. We may compare the gouty state to the mycelium which permeates the soil of a mushroom bed , the acute attacks to the mushrooms which appear upon the surface from time to time Whereas there is no reason to suppose that uric acid is the cause of the gouty state, there is good reason to suppose that the accumulation of uric acid in the blood is the cause of the outward manifestations of that state The main principles of the treatment of gout by diet are much older than our knowledge of that derangement of the excretion, or of the metabolism, of uric acid which is its outstanding and distinctive pathological feature These principles are grounded upon foundations of clinical experience throughout centuries, were recognised at the beginning of the Christian era and are hardly likely to be shaken by the greater knowledge of the pathology of the disease which the future doubtless has in store for us

There can be no question that throughout history gout has tended to become prevalent amongst peoples who, after periods of stress and struggle, have attained to conditions of material well being, who have aggregated into cities which became the centres of increasing luxury and more elaborate civilisation Thus, in Rome, gout was evidently very prevalent in Imperial times Such documents as the letters of the younger Pliny bear witness to this fact, and, writing of his friend Cornelius Rufus, whose sufferings had driven him to suicide, Pliny tells how in his earlier years he had kept his gout in check by abstemiousness and self restraint, and adds that in this case the disease was hereditary, "for maladies, like other things, are often transmitted in a kind of succession' , probably the earliest extant statement to that effect To Byzantium, again, we owe some of our best remedies for gout

Nowadays England has the unenviable reputation of being the country in which gout is most prevalent Among the wealthier classes this may be attributable in part to traditions of high living and free consumption of protein foods common in such a climate as ours, and to the drinking of the heavier kinds of beers and wines But these cannot be the only causes of the prevalence of gout amongst us Our lower orders certainly live in no conditions of luxury, nor is the consumption of meat amongst them excessive, and yet amongst the poor who apply for treatment in the out patient departments of our London hospitals are many sufferers from gout in its most characteristic forms In Scotland, on the other hand, the disease is rarely seen in hospital patients If this difference between the two peoples inhabiting different parts of the same island and united under the same Crown is to be explained by any dietetic difference, we shall be tempted to ascribe it to the fact that, whereas the Englishman of the labouring class habitually drinks beer, the Scotsman of the same class drinks whisky

However, we shall not do well to concentrate our attention upon diet alone The dweller in cities is placed in abnormal circumstances Cases are recorded of men who in the days of their prosperity had suffered much from gout, but who having been compelled by reverse of fortune to adopt a frugal and laborious mode of life have been free thenceforward from its manifestations Far commoner is the converse case of the man who after a frugal upbringing in the country has adopted a sedentary city life, has given more rein to his appetite and more strain to his digestion, and who has been the first member of his family to exhibit the disease At the present time the well to do classes in England probably eat much less meat and certainly drink much less port wine, than their forefathers did, and there is a widespread impression amongst us that tophaceous gout with extensive deposits of urate in the tissues is far less common than it used to be My own experience leads me to believe that this is true Certainly my countrymen do not fall behind men of other races in the cult of bodily exercise, and men of middle age—scholars statesmen and professional men included—who have entered upon what may be styled the gouty period of life, usually take pains to cultivate some active pursuit The vogue of the game of golf has brought such exercise within the reach of our city dwellers of all ages, and in so doing has diminished the temptation to neglect such aids to physical well being

The important part played by heredity in connexion with gout cannot be questioned but it is difficult to reconcile with modern conceptions of the workings of heredity the idea so often expressed that because our ancestors drank freely of port wine their descendants have acquired a liability to the malady It is easier to suppose that what is inherited is a tissue state which renders an individual liable to acquire gout on slight provocation It is an evident fact that one man will develop gout if he deviate but slightly from the optimum course of life, whilst another fails to manifest the disease in spite of continuous and glaring indiscretions of diet and regimen Failing a favourable environment, the tendency latent in a family may not show itself and may remain unsuspected , but the rise of a member of it to easy circumstances may bring it to the surface, the nature of gout, and of what should and should not be suitable foods for those who suffer from its attacks There can be little doubt that in their main features the current tenets as to the dietetic treatment of gout rest upon a sound basis, but many details of advice which are given could with difficulty be defended in argument How insecure is the footing of many of them is shown by their great diversity. Hardly an article of diet can be mentioned which someone will not be found to forbid

The members of one school among us, of which Dr A Haig is the protagonist, would extend the connotation of gout to include a large proportion of the ills of humanity, regard uric acid as the underlying cause of all the morbid states included, and a purin free diet as the sovereign preventive of them I would range myself with those who take a much narrower view of the range of gout, and would restrict the name to morbid conditions which stand in an obvious clinical relationship to genuine podagra Even if we confine our ideas of gout within such narrow limits we still find ourselves confronted by two more or less distinct therapeutic problems—namely, How best to avert the development of the gouty state, and how to control the active

long periods, yet he who develops an acute attack in his great toe once a year, or once in two years, has latent gout in the intervals, and does not develop the malady afresh with each attack. We may compare the gouty state to the mycelium which permeates the soil of a mushroom bed, the acute attacks to the mushrooms which appear upon the surface from time to time Whereas there is no reason to suppose that uric acid is the cause of the gouty state, there is good reason to suppose that the accumulation of uric acid in the blood is the cause of the outward manifestations of that state The main principles of the treatment of gout by diet are much older than our knowledge of that derangement of the excretion, or of the metabolism, of uric acid which is its outstanding and distinctive pathological feature These principles are grounded upon foundations of clinical experience throughout centuries, were recognised at the beginning of the Christian era and are hardly likely to be shaken by the greater knowledge of the pathology of the disease which the future doubtless has in store for us

There can be no question that throughout history gout has tended to become prevalent amongst peoples who, after periods of stress and struggle, have attained to conditions of material well being, who have aggregated into cities which became the centres of increasing luxury and more elaborate civilisation Thus, in Rome, gout was evidently very prevalent in Imperial times Such documents as the letters of the younger Pliny bear witness to this fact, and, writing of his friend Cornelius Rufus, whose sufferings had driven him to suicide, Pliny tells how in his earlier years he had kept his gout in check by abstemiousness and self restraint, and adds that in this case the disease was hereditary, "for maladies, like other things, are often transmitted in a kind of succession', probably the earliest extant statement to that effect To Byzantium, again, we owe some of our best remedies for gout

Nowadays England has the unenviable reputation of being the country in which gout is most prevalent Among the wealthier classes this may be attributable in part to traditions of high living and free consumption of protein foods common in such a climate as ours, and to the drinking of the heavier kinds of beers and wines But these cannot be the only causes of the prevalence of gout amongst us Our lower orders certainly live in no conditions of luxury, nor is the consumption of meat amongst them excessive, and yet amongst the poor who apply for treatment in the out patient departments of our London hospitals are many sufferers from gout in its most characteristic forms In Scotland, on the other hand, the disease is rarely seen in hospital patients If this difference between the two peoples inhabiting different parts of the same island and united under the same Crown is to be explained by any dietetic difference, we shall be tempted to ascribe it to the fact that, whereas the Englishman of the labouring class habitually drinks beer, the Scotsman of the same class drinks whisky

However, we shall not do well to concentrate our attention upon diet alone The dweller in cities is placed in abnormal circumstances Cases are recorded of men who in the days of their prosperity had suffered much from gout, but who having been compelled by reverse of fortune to adopt a frugal and laborious mode of life have been free thenceforward from its manifestations Far commoner is the converse case of the man who after a frugal upbringing in the country has adopted a sedentary city life, has given more rein to his appetite and more strain to his digestion, and who has been the first member of his family to exhibit the disease At the present time the well to do classes in England probably eat much less meat and certainly drink much less port wine, than their forefathers did, and there is a widespread impression amongst us that tophaceous gout with extensive deposits of urate in the tissues is far less common than it used to be My own experience leads me to believe that this is true Certainly my countrymen do not fall behind men of other races in the cult of bodily exercise, and men of middle age—scholars statesmen and professional men included—who have entered upon what may be styled the gouty period of life, usually take pains to cultivate some active pursuit The vogue of the game of golf has brought such exercise within the reach of our city dwellers of all ages, and in so doing has diminished the temptation to neglect such aids to physical well being

The important part played by heredity in connexion with gout cannot be questioned but it is difficult to reconcile with modern conceptions of the workings of heredity the idea so often expressed that because our ancestors drank freely of port wine their descendants have acquired a liability to the malady It is easier to suppose that what is inherited is a tissue state which renders an individual liable to acquire gout on slight provocation It is an evident fact that one man will develop gout if he deviate but slightly from the optimum course of life, whilst another fails to manifest the disease in spite of continuous and glaring indiscretions of diet and regimen Failing a favourable environment, the tendency latent in a family may not show itself and may remain unsuspected, but the rise of a member of it to easy circumstances may bring it to the surface, and the recognition of the fact that it is possible to prescribe a diet rich in protein, but at the same time almost free from purins. Their almost complete freedom from purins gives to milk, eggs, and cheese a special claim to be suitable foods for gouty people, and I believe that the less rigid restriction of proteins than was formerly in vogue is for the benefit of our patients.

Of all foods, sweetbreads, both pancreas and thymus gland, are the richest in purins. They are often recommended as suitable foods for invalids, including sufferers from gout, presumably because they are soft and easily digested. Dr. A. P. Luff, in a recent article on the treatment of gout, writes as follows: "From Walker Hall's experiments it would appear reasonable to administer sweetbread to gouty patients, since its nuclein portion is only slightly absorbed; for thymus sweetbread contains principally adenin, which is rapidly excreted, and pancreas sweetbread contains mainly guanin, an amino-purin incapable of increasing the urinary purin output and of exerting any injurious effects upon the tissues." Seeing, however, that it has been clearly demonstrated that their administration to a healthy man is followed by a much increased excretion of uric acid, and that this increase has been found to be less pronounced in the case of a gouty subject, it would certainly appear to be advisable to eliminate from the diet foodstuffs which are open to so grave suspicion, and which can so easily be dispensed with. There are cases, indeed, in which free feeding on thymus has appeared to be the direct cause of an attack of gout. If the knowledge which we possess does not justify us in pronouncing sweetbreads to be undesirable food for gouty people, we must admit that we are not yet in a position to give any advice on this subject on scientific, as distinguished from empirical, lines. Strong meat soups, sauces, and gravies, also are contraindicated, on account of the extractives which they contain, and with which they are often fortified.

Of scarcely less importance than the nature and quantity of protein food taken is the manner in which it is cooked. It is generally agreed that twice cooked meat is less digestible, and therefore less suited to gouty people, than that which has not been so treated; and that elaborately made-up dishes rich in extractives, and in the preparation [illegible], should be avoided.

[illegible] have an important place [illegible] prescribing them several points have to be taken into account. Some vegetables contain no inconsiderable amounts of purin; others are undesirable because difficult of digestion. On the other hand, some vegetable foods are of service on account of the bulky residue which they yield, whereas others are esteemed because of their inorganic constituents and their richness in potassium salts. Leaf vegetables, provided that they are well cooked and of digestible kinds, are usually to be pre[illegible] the exception of potato. [illegible] by Sir Dyce Duckworth, [illegible] rich in oxalate, should [illegible]nt. Tomatoes meet with [illegible]en belief [illegible], oranges [illegible] by most [illegible]ms and [illegible]lly taken place, are better avoided.

It should be remembered that a food essentially harmful may be habitually taken in such small quantities that it becomes negligible, whereas another, much less inherently harmful, may do more harm because it is taken freely. Thus, pepper is very rich in oxalate, but it is hardly worth while to forbid it to a sufferer from oxaluria. Some vegetable foodstuffs which are specially palatable, and which are only to be obtained during a short season in each year, are apt to be taken in excess at such times. Asparagus and strawberries may be placed in this class, and if taken sparingly they probably do no appreciable harm. Very many gouty persons are convinced that strawberries are bad for them, and the fact that in some persons they produce urticaria shows that they contain constituents which may be classed as toxic. In spite of Linnæus's testimonial to their value as preventives of gout, I habitually advise my gouty patients to avoid them.

Carbohydrate foods.—In England one of the most firmly rooted impressions on these matters is that sugar is a peculiarly harmful article of diet for gouty people, who, in reply to inquiries as to what they eat, drink, and avoid, usually begin by saying that of course they never touch sugar. Nevertheless, those who eschew sugar often take starch foods freely. It seems clear that the basis of such exclusion is the great tendency of many sweet foods to upset digestion, and although on theoretical grounds carbohydrates should be suitable foods for the gouty, they are certainly unsuitable if taken in excess, and our patients are well advised to partake of sweet dishes sparingly, or not at all. They should take their carbohydrates mainly in the form of bread, potatoes, and milky puddings; and new bread should be avoide[illegible] the other hand, [illegible] man a lump of [illegible] digestible, it must surely be immaterial whether the allowance of carbohydrates be taken in the form of sugar or starch.

Fats.—The third great group of food constituents, the fats, apparently are suitable foods for the gouty, but here again much depends upon the form in which they are taken. The rich browned fat of roast meat is apt to upset digestion, and should be avoided. In certain cases, as when there is a tendency to obesity, the intake both of carbohydrates and fats calls for restriction; and when glycosuria is a symptom a still further limitation of carbohydrates may be necessary. In such circumstances a diet of compromise must be resorted to, adequate in calorie value, and which, although it may not be the optimum diet from any one point of view, is the best that can be devised for the individual patient.

Extreme dietaries.—In special cases extreme dietaries may be of use, as temporary expedients, such as one which aims at the exclusion of all purin substances, or which, like the Salisbury diet, consists almost exclusively of meat. The former may be of service in getting rid of accumulated uric acid, and the latter in checking intestinal fermentation; but, for my own part, I am convinced that no diet which excludes one or more of the main ingredients of human food, or even a minor constituent such as the purins, can be regarded as a desirable one over long periods. Whilst such a regimen, which may be described as eccentric, in the scientific sense of the term, is being followed, the organism is placed under abnormal conditions, and such conditions can hardly be maintained with impunity for an indefinite length of time.

[illegible] doubt that [illegible] in certain [illegible]lcohol may appear advisable. It can hardly be doubted that the consensus of opinion which assigns to certain alcoholic drinks a very important, if not the chief, rôle in the causation of gout and of its manifestations is based upon a mass of experience so great as to command assent. It is probable that the effervescent alcoholic drinks, such as champagne and the heavier beers and stouts, are the worst offenders, but the heavier still wines, such as port and sherry, come very near to them in this respect. In Scotland, as has been mentioned, gout is comparatively rare, especially among the poorer classes, who, although they do not take alcohol less freely than their English brethren, drink whisky rather than beer; and it is probably on this account that whisky has been so widely adopted amongst us as a suitable alcoholic drink for the gouty. However, its vogue is not now so great as a few years ago, when many subjects of gout appeared to entertain the notion that whisky was not merely less harmful than other alcoholic drinks, but was actually beneficial. Now, again, the lighter white wines, such as still Moselle and Rhine wines, are in special favour—such are the changes of fashion in diet as in other things. I have known not a few gouty patients who have assured me that they have found in cider an alcoholic drink which suited them admirably, but an experience of some months has usually modified their opinion on this point.

There is another widely held impression amongst us that hard waters are bad for the gouty, and some authorities, including my teacher Sir Dyce Duckworth hold this view. If they be detrimental, it is probable that they owe their ill effects to their tendency to increase constipation. The tradition on this matter is of no recent development. Scudamore wrote as follows in 1823: "The kind of water denominated hard has always been considered as unfriendly and the recognition of the fact that it is possible to prescribe a diet rich in protein, but at the same time almost free from purins. Their almost complete freedom from purins gives to milk, eggs, and cheese a special claim to be suitable foods for gouty people, and I believe that the less rigid restriction of proteins than was formerly in vogue is for the benefit of our patients.

Of all foods, sweetbreads, both pancreas and thymus gland, are the richest in purins. They are often recommended as suitable foods for invalids, including sufferers from gout, presumably because they are soft and easily *digested*. Dr. A. P. Luff, in a recent article on the treatment of gout, writes as follows: "From Walker Hall's experiments it would appear reasonable to administer sweetbread to gouty patients, since its nuclein portion is only slightly absorbed; for thymus sweetbread contains principally adenin, *which is rapidly excreted*, and pancreas sweetbread contains mainly guanin, an amino-purin incapable of increasing the urinary purin output and of exerting any injurious effects upon the tissues." Seeing, however, that it has been clearly demonstrated that their administration to a healthy man is followed by a much increased excretion of uric acid, and that *this increase* has been found to be less pronounced in the case of a gouty subject, it would certainly appear to be advisable to eliminate from the diet foodstuffs which are open to so grave suspicion, and which can so easily be dispensed with. There are cases, indeed, in which free feeding *on thymus has appeared to be the direct cause of an attack of* gout. If the knowledge which we possess does not justify us in pronouncing sweetbreads to be undesirable food for gouty people, we must admit that we are not yet in a position to give any advice on this subject on scientific, as distinguished from empirical, lines. Strong meat soups, sauces, and gravies, also are contraindicated, on account of the extractives which they contain, and with which they are often fortified.

Of scarcely less importance than the nature and quantity of protein food taken is the manner in which it is cooked. It is generally agreed that twice cooked meat is less digestible, and therefore less suited to gouty people, than that which has not been so treated; and that elaborately made-up dishes rich in extractives, and in the preparation [illegible] l, should be avoided.

[illegible] have an important place [illegible] prescribing them several points have to be taken into account. Some vegetables contain no inconsiderable amounts of purin; others are undesirable because difficult of digestion. On the other hand, some vegetable *foods are of service on account of the* bulky residue which they yield, whereas others are esteemed because of their inorganic constituents and their richness in potassium salts. Leaf vegetables, provided that they are well cooked and of digestible kinds, are usually to be pre[illegible] the exception of potato. [illegible] by Sir Dyce Duckworth, [illegible] rich in oxalate, should [illegible]nt. Tomatoes meet with [illegible]en belief [illegible], oranges [illegible] by most [illegible]ms and [illegible]lly taken place, are better avoided.

It should be remembered that a food essentially harmful may be habitually taken in such small quantities that it becomes negligible, whereas another, much less inherently harmful, may do more harm because it is taken freely. TWO CASES OF VEIN-GRAFTING FOR THE MAINTENANCE OF A DIRECT ARTERIAL CIRCULATION.

BY J. HOGARTH PRINGLE, M.B., C.M. EDIN., F.R.C.S. ENG.,
SURGEON TO THE GLASGOW ROYAL INFIRMARY.

THE reports of the two following cases are published as examples of the successful application, in human surgery, of the lessons that have been taught by the splendid work of Carrel in his experimental studies on the surgery of the vascular system. They are not the first cases to be recorded, but I am not aware that any instances of the employment of vascular grafting have been published in Great Britain.

CASE 1: *Popliteal aneurysm treated by excision; restoration of arterial continuity by a vein graft.*—The patient, a man aged 49, was admitted to the Royal Infirmary, Glasgow, on May 1st, 1912, complaining of a "throbbing swelling behind the left knee." He stated that he had had all the infective diseases of childhood, and an attack of rheumatism at the age of 24 years, when he was confined to bed for four weeks. He denied having had syphilis. He was married; his wife had had four children, all of whom were well, and one miscarriage between the second and third labours. He first observed a swelling behind [illegible] his admission to hospital, [illegible] time "about the size of [illegible] pulse." Since then the swelling had enlarged steadily it slowly. There was a history of his having fallen backwards over some scrap-iron, and of striking the back of the left [illegible]

attendant, Dr. W. Campbell, of Springburn, regarding the tumour some three months before he came to hospital, and was then advised by him to seek admission, but did not do so, and continued at his work until April 30th, the day before he came into my ward.

The patient was of medium build; his lungs, liver, and spleen appeared to be normal. The heart was slightly enlarged, and there was a double murmur heard over the aortic area. The left popliteal space was occupied by an oval-shaped swelling which had an expansile pulsation. The skin over it was tense and glazed. A thrill was felt over the tumour, and by auscultation a harsh bruit could be heard over it. The circumference of the two knee-joints, measured at the centre of the patella, was—right knee, 33 cm.; left knee, 36·5 cm. The pulse in the left posterior tibial artery felt at the ankle was sluggish and behind that of the right tibial in point of time. The superficial veins of both limbs up to the knee-joints were decidedly varicose, but those of the right leg were as bad as those of the left. The diagnosis of aneurysm was quite clear. The patient's blood gave a very positive Wassermann's reaction.

On May 16th the aneurysm was excised; it lay external to the popliteal vein and the nerve. The vein was closely adherent to the sac throughout its length and lay deeper than the sac—i.e., nearer the femoral than the superficial aspect of the sac. The sac itself was for the most part empty, but in its proximal portion contained some firm clot, and at this part was [illegible] structures. The artery [illegible] beyond the origin of th[illegible] lines of section being fully two inches; the vessel was clamped first on each side of the sac. I had hoped that it might be possible to attempt an end-to-end anastomosis of the two segments of the vessel; but even with the knee-joint flexed it was not possible to approximate the two ends nearer than to one inch of one another. Rather than ligate the two ends of t[illegible] maintain the continuity of [illegible] grafting [illegible] cordingly a portion of the [illegible] four inches of the internal saphena vein were removed from the middle of the right thigh and sutured to the cut ends of the artery by Carrel's method of circular suture; care was taken that the distal end of the segment of vein was sutured to the proximal segment of the artery in case there might be a valve in the portion of vein used, which would have seriously interfered with the passage of the blood through it. The length of vein excised exactly fitted the space between the two cut ends of the artery, which had retracted considerably.

The clamp that had been placed upon the distal side of the aneurysm was first removed, but the blood did not fill up, or even run into, the artery and grafted vein as I had expected, showing, I believe, that the collateral circulation was not efficient. After waiting several minutes to see if the backward flow of blood would fill up the vessels, but without result, the proximal clamp was removed from the artery, and at once blood rushed through the graft into the distal arteries. Not one drop of blood escaped at either of the lines of suture, so that nothing further was required than to suture up the wound in the overlying tissues and to apply a dressing. The limb was placed upon a posterior splint. From the moment, practically, of removing the proximal clamp from the artery the posterior tibial pulse in the two limbs seemed to be equal in force and time. The patient was kept in bed for three weeks and went home on June 14th, and at that time the pulsations along the course of the grafted vein were easily seen as well as felt.

[illegible] in. [illegible] rior [illegible] by a distance of about two inches, but between these two openings no trace whatever of any furrow or trough suggesting the remainder of the lumen of the artery is to be made out.

The patient resumed his ordinary work on August 1st, 1912, and has continued steadily at it since. He has been seen on several occasions; the last time was, Feb. 7th, when he was brought before the Glasgow Medico-Chirurgical Society. The posterior tibial pulses appear to be equal in time and force, and the pulsations of the popliteal artery can still be seen as well as felt. The grafted vein, therefore, remains perfectly patent.

CASE 2. *Traumatic aneurysm of the brachial artery; vein-grafting.*—The patient, a lad aged 19, a blacksmith, was admitted to the Royal Infirmary on Feb. 24th, 1913, complaining of a swelling at the right elbow and inability to use the arm. The patient's medical history was good; he could not remember any previous illness. Five weeks before admission to hospital he had received an injury to the right upper limb; he was working at a steel railway rail when a fragment of steel flew off and penetrated the tissues just above his right elbow anteriorly. The small wound bled profusely at the time; a dressing was applied, and by the time he got home a swelling of some size had developed in front of the right elbow, causing him much pain at first. The swelling was at first soft, but as it became much firmer the pain practical[illegible] ing was not very [illegible] of the day of the [illegible] Dr. W. L. Cullen, [illegible]

There was a *swelling of some extent occupying* the bend of the right elbow, hard, and brawny rather to feel, extending up into the arm and down into the forearm. In the skin about one inch above the line of the articulation, and just *inside* the *mesial* line of the limb, there was a small scar half an inch long, the result of the wound. The swelling was most prominent to the inner aspect of the limb and was fairly well defined. A faint thrill could be felt over the inner portion, and a bruit could be heard over the greater part of the tumour. Pulsation could not be detected. The right radial pulse was smaller than the left, and was decidedly delayed. There was no loss of sensation in the hand or forearm. The elbow-joint could not be fully extended, and could not be flexed actively more than to make an angle, open forwards, of about 120°, owing to the presence of the tumour, and any passive attempt to flex further was associated with pain. The hand was held about midway between pronation and *supination, very little* movement in either direction being permitted. There was no varicosity of the veins of the limb. An examination of the part under X rays showed the presence of a small foreign body lying close against the humerus immediately above the coronoid fossa.

On the evening of Feb. 26th, although the patient had

TWO CASES OF VEIN-GRAFTING FOR THE MAINTENANCE OF A DIRECT ARTERIAL CIRCULATION.

BY J. HOGARTH PRINGLE, M.B., C.M. EDIN., F.R.C.S. ENG.,
SURGEON TO THE GLASGOW ROYAL INFIRMARY.

THE reports of the two following cases are published as examples of the successful application, in human surgery, of the lessons that have been taught by the splendid work of Carrel in his experimental studies on the surgery of the vascular system. They are not the first cases to be recorded, but I am not aware that any instances of the employment of vascular grafting have been published in Great Britain.

CASE 1. *Popliteal aneurysm treated by excision; restoration of arterial continuity by a vein graft.*—The patient, a man aged 49, was admitted to the Royal Infirmary, Glasgow, on May 1st, 1912, complaining of a "throbbing swelling behind the left knee." He stated that he had had all the infective diseases of childhood, and an attack of rheumatism at the age of 24 years, when he was confined to bed for four weeks. He denied having had syphilis. He was married; his wife had had four children, all of whom were well, and one miscarriage between the second and third labours. He first observed a swelling behind [illegible] his admission to hospital, [illegible] time "about the size of [illegible] pulse." Since then the swelling had enlarged steadily it slowly. There was a history of his having fallen backwards over some scrap-iron, and of striking the back of the left [illegible] attendant, Dr. W. Campbell, of Springburn, regarding the tumour some three months before he came to hospital, and was then advised by him to seek admission, but did not do so, and continued at his work until April 30th, the day before he came into my ward.

The patient was of medium build; his lungs, liver, and spleen appeared to be normal. The heart was slightly enlarged, and there was a double murmur heard over the aortic area. The left popliteal space was occupied by an oval-shaped swelling which had an expansile pulsation. The skin over it was tense and glazed. A thrill was felt over the tumour, and by auscultation a harsh bruit could be heard over it. The circumference of the two knee-joints, measured at the centre of the patella, was—right knee, 33 cm.; left knee, 36·5 cm. The pulse in the left posterior tibial artery felt at the ankle was sluggish and behind that of the right tibial in point of time. The superficial veins of both limbs up to the knee-joints were decidedly varicose, but those of the right leg were as bad as those of the left. The diagnosis of aneurysm was quite clear. The patient's blood gave a very positive Wassermann's reaction.

On May 16th the aneurysm was excised; it lay external to the popliteal vein and the nerve. The vein was closely adherent to the sac throughout its length and lay deeper than the sac—i.e., nearer the femoral than the superficial aspect of the sac. The sac itself was for the most part empty, but in its proximal portion contained some firm clot, and at this part was [illegible] structures. The artery [illegible] beyond the origin of th[illegible] lines of section being fully two inches; the vessel was clamped first on each side of the sac. I had hoped that it might be possible to attempt an end-to-end anastomosis of the two segments of the vessel; but even with the knee-joint flexed it was not possible to approximate the two ends nearer than to one inch of one another. Rather than ligate the two ends of t[illegible] maintain the continuity of [illegible] grafting a portion of the [illegible] cordingly four inches of the internal saphena vein were removed from the middle of the right thigh and sutured to the cut ends of the artery by Carrel's method of circular suture; care was taken that the distal end of the segment of vein was sutured to the proximal segment of the artery in case there might be a valve in the portion of vein used, which would have seriously interfered with the passage of the blood through it. The length of vein excised exactly fitted the space between the two cut ends of the artery, which had retracted considerably.

The clamp that had been placed upon the distal side of the aneurysm was first removed, but the blood did not fill up, or even run into, the artery and grafted vein as I had expected, showing, I believe, that the collateral circulation was not efficient. After waiting several minutes to see if the backward flow of blood would fill up the vessels, but without result, the proximal clamp was removed from the artery, and at once blood rushed through the graft into the distal arteries. Not one drop of blood escaped at either of the lines of suture, so that nothing further was required than to suture up the wound in the overlying tissues and to apply a dressing. The limb was placed upon a posterior splint. From the moment, practically, of removing the proximal clamp from the artery the posterior tibial pulse in the two limbs seemed to be equal in force and time. The patient was kept in bed for three weeks and went home on June 14th, and at that time the pulsations along the course of the grafted vein were easily seen as well as felt.

[illegible] in. [illegible] rior [illegible] by a distance of about two inches, but between these two openings no trace whatever of any furrow or trough suggesting the remainder of the lumen of the artery is to be made out.

The patient resumed his ordinary work on August 1st, 1912, and has continued steadily at it since. He has been seen on several occasions; the last time was Feb. 7th, when he was brought before the Glasgow Medico-Chirurgical Society. The posterior tibial pulses appear to be equal in time and force, and the pulsations of the popliteal artery can still be seen as well as felt. The grafted vein, therefore, remains perfectly patent.

CASE 2. *Traumatic aneurysm of the brachial artery; vein-grafting.*—The patient, a lad aged 19, a blacksmith, was admitted to the Royal Infirmary on Feb. 24th, 1913, complaining of a swelling at the right elbow and inability to use the arm. The patient's medical history was good; he could not remember any previous illness. Five weeks before admission to hospital he had received an injury to the right upper limb; he was working at a steel railway rail when a fragment of steel flew off and penetrated the tissues just above his right elbow anteriorly. The small wound bled profusely at the time; a dressing was applied, and by the time he got home a swelling of some size had developed in front of the right elbow, causing him much pain at first. The swelling was at first soft, but as it became much firmer the pain practical[illegible] ing was not very [illegible] of the day of the [illegible] Dr. W. L. Cullen, [illegible]

There was a swelling of some extent occupying the bend of the right elbow, hard, and brawny rather to feel, extending up into the arm and down into the forearm. In the skin about one inch above the line of the articulation, and just inside the mesial line of the limb, there was a small scar half an inch long, the result of the wound. The swelling was most prominent to the inner aspect of the limb and was fairly well defined. A faint thrill could be felt over the inner portion, and a bruit could be heard over the greater part of the tumour. Pulsation could not be detected. The right radial pulse was smaller than the left, and was decidedly delayed. There was no loss of sensation in the hand or forearm. The elbow-joint could not be fully extended, and could not be flexed actively more than to make an angle, open forwards, of about 120°, owing to the presence of the tumour, and any passive attempt to flex further was associated with pain. The hand was held about midway between pronation and supination, very little movement in either direction being permitted. There was no varicosity of the veins of the limb. An examination of the part under X rays showed the presence of a small foreign body lying close against the humerus immediately above the coronoid fossa.

On the evening of Feb. 26th, although the patient had produces a fatal effect on [illegible] sensitisation two whole heated agar cultures (20–30 times the previous dose) can be injected into a mouse without producing any symptoms at all. The dysentery bacillus is also very toxic, even when killed. After sensitisation, however, 100 times the dose previously fatal may be given to mice without harmful effect. These experiments, and others to which I have alluded elsewhere, demonstrate the pronounced effect of sensitisation in reducing the toxicity of a vaccine.

The question may next be asked, But is not this reduction of toxicity effected at the expense of the immunising capacity of the vaccine? The animal experiments show that this is not so. Experiments with the typhoid bacillus, plague, cholera, dysentery, streptococcus, and pneumococcus indicate that the immunity resulting from sensitised vaccine is as "solid" as that resulting from an ordinary vaccine. They show, moreover, that sensitisation has the very important effect of accelerating the onset of the immunity, and, further, that between the time of injection of a sensitised vaccine and the onset of the resulting immunity there is no diminution in the animal's resistance.

From these experiments on animals, then, it would appear that sensitisation of a vaccine has three important advantages: (1) the reaction is eliminated, (2) immunity is accelerated, and (3) this immunity is achieved without any diminution in the animal's specific resistance.

How are these results to be accounted for?—The commoner pathogenetic bacteria—e g., streptococci, pneumococci, B. coli, B. typhosus, B. tuberculosis, &c.—all act by reason of their endotoxin. During sensitisation the bacterial bodies become coated with agglutinin and opsonin. The endotoxin is not neutralised—at any rate completely—but merely covered over. When a sensitised vaccine is injected into the body these prepared bacteria, thanks to their opsonification, are at once taken up by the body cells, and especially by the polymorphonuclear leucocytes. The endotoxin is not set free until the bacterial cell is lysed in the interior of the phagocytes; and these phagocytes being the chief factory of antibodies, their interior is the very place which we wish to stimulate in a bacterial infection.

[illegible] to promote its [illegible] is to accelerate [illegible] of the phago- [illegible] the endotoxin [illegible] corresponds with that already put forward by Broughton-Alcock, seems to be the most likely explanation of the mode of action of sensitised vaccine. Whatever the *modus operandi* there is no doubt about the resulting immunity; and the advantage of the method of Besredka is that this is achieved without a reaction, without any trouble from horse serum; speedily; and without producing any diminution in the animal's specific resistance.

The chief experimental work with sensitised vaccines has been done for purposes of prophylaxis. Experiments as to their curative value are less abundant. A striking piece of research, however, in this sense has been carried out by Levy and Aoki with the pneumococcus on rabbits. They first of all compared the immunising values of ordinary and sensitised pneumococcal vaccine prophylactically, and found that the sensitised vaccines gave best results. They also found that exceedingly good immunity resulted from vaccinating by the intensive method of Fornet and Müller, according to which increasing doses of vaccine are given for three days in succession. Finally, they injected rabbits with a fatal dose of living pneumococci, and found that they could save the lives of these animals by giving them large enough doses of sensitised pneumococci killed by phenol.

In view of these encouraging results on animals it was clearly desirable to ascertain the value of sensitised vaccines on man, especially in the treatment of acute bacterial infections. Through the cordial cooperation of the clinical staff at St. Bartholomew's it has been possible to do this in a series of cases which I am now, through their courtesy, permitted to report.

Before dealing with the results I will ask you to consider for a moment the nature of the problem. We are dealing with a patient whose infection is in active progress and whose general condition is sufficiently serious to justify admission to hospital. Some of the cases of which I shall [illegible] at the stage when the treatment was applied that there was grave doubt as to their recovery.

The first question is, What would a sensitised vaccine be expected to do in such a case? Now, the method being one of stimulating the patient's specific resistance, it is clear before we start that the main factor in a patient's recovery from an acute bacterial infection must always be his own general resistance. All that we can hope to do with a method such as the present one is to bring out his specific resistance to the utmost extent possible and in the speediest time—in short, to *accelerate* the immunising mechanism of the patient. I think you will agree that if we are able to do this without detriment to the patient in other respects, [illegible] certain cases is likely [illegible] raise is this: How are we to judge of the effect of a sensitised vaccine on such a patient? There can be only one answer. The effect will be seen by comparing the clinical condition of the patient—both local and general—before and after the vaccine is given. I am showing the temperature charts of these cases. But the temperature, of course, is only one point in the illness. I[illegible] the patient, his [illegible] ping, [illegible] the [illegible] hout the same degree of improvement showing in the temperature chart. Bearing this in mind, however, it must be admitted that in an acute bacterial infection the temperature forms on [illegible] as good and impartial an index of the patient's [illegible] fic treatment. The great majority were instances of infection by [illegible] were injected with stock [illegible] accine made by mixing [illegible] pyogenes and sensitising [illegible] *sensitisation by adding* 1 per cent. of phenol. In giving the vaccine the intensive method of Fornet and Muller was chiefly used—increasing doses being injected subcutaneously for three days in succession.

Notes of Cases.

A PRACTICAL METHOD OF GROWING THE ACNE BACILLUS FROM THE COMEDO

FOR THE PREPARATION OF VACCINES

BY T H C BENIANS, M R C S ENG , L R C P LOND ,
JUNIOR ASSISTANT, INOCULATION DEPARTMENT, LONDON HOSPITAL

(*From the Bacteriological Department London Hospital Medical College* Professor W BULLOCH F R S , *Director*)

No attempt is made to enter at length into the controversial topic of the etiology of the disease The relationship of the staphylococcus and acne bacillus as causative agents of the various lesions coming under the head of acne vulgaris is still to some extent unsettled In passing, however the writer gives it as his opinion that judging on present evidence the acne bacillus is the agent chiefly concerned in the immediate production of the skin lesions Among these very protean lesions some are from their anatomical position completely beyond the scope of vaccine therapy , in others the conditions are ideal for attaining the best results by this method of treatment

It is taken that the position of vaccines in the treatment of this disease although not entirely satisfactory, is yet sufficiently well established , the question now remains as to the relative values of autogenous as compared with stock vaccines As a general rule at any rate in hospital practice it is customary to use a stock vaccine so that this question has probably not yet been sufficiently well tested In staphylococcal lesions we know that occasionally an autogenous vaccine may effect a cure where a stock vaccine has failed and this although we are unable to differentiate varied strains of staphylococcus aureus In the case of the acne lesions we have some evidence already that the organisms found in the lesions belong to a large and varied group of bacilli

In a number of cases under treatment by the author the patients were changed from treatment with a stock acne vaccine to an autogenous vaccine with very beneficial results , in some cases a complete cure of the pustular lesions was quickly effected Data by other workers on this subject are however, needed because no more direct proof than a general consensus of opinion is possible It may well be that some or many of the numerous failures in the treatment of acne by vaccines are to be attributed to the use of a stock vaccine, which vaccine may have been prepared from an organism totally different in its characters from that growing on and in the patient s skin

Although the cultural characteristics of the acne bacillus are now fairly well known the preparation of an autogenous vaccine for a patient remains still a matter of considerable difficulty The principal methods of isolation and culture so far published are those described by Fleming[1] and by Sudmerson and Thompson [2] Fleming advocated the use of an oleic acid agar , he obtained the material from the smaller pustules, and grew it in the first instance anaerobically The latter-named writers use an acid serum agar , they take the deeper parts of the comedo in which the acne bacillus usually predominates, emulsify this in saline, and spread thinly on the slope, so that they may obtain isolated colonies to pick off They also made the first cultures anaerobically Most workers however, agree that to enable the acne bacillus to start growing on artificial media a considerable mass of the infective material must be planted, even on a medium which is favourable to the growth of the organism When this is done it mostly happens that there are sufficient staphylococci present to overgrow the more slowly growing acne bacillus

The method used by the writer does not aim at producing the organism in a state of bacteriological purity The aim of the procedure is to supply in a reasonably short time a sufficiently free growth of the acne bacillus for the purpose of preparing a vaccine In the more complete methods, moreover the bacteriologist must himself remove the pus, or the comedo, from the patient and at once proceed to select the required parts of it and to plant them out under anaerobic conditions By the simple method here described the bacteriologist requires merely one or two comedones, whether expressed a few minutes or days before is immaterial

As will be seen, a very small proportion of staphylococci are almost invariably present but these may be treated as a negligible factor The proportion of staphylococci present is not more than about 10 per cent at the most , thus in giving an average dose of the acne vaccine say 5 000 000, one is giving at the same time 500 000 staphylococci Since an average dose of the staphylococci, perhaps to be given at the same time with the acne is not likely to be less than 250 000 000 the original 500,000 contained in the acne vaccine may well be overlooked

Variations in the bacteriology of the comedo —The bacteriology of the comedo varies greatly from a quantitative point of view Almost always both staphylococci and acne bacilli are present The staphylococcus may be said to be invariably present , the acne bacillus is sometimes though rarely absent The average sebaceous plug contains acne bacilli greatly in excess of the staphylococci which latter are mainly present in the superficial part If such a comedo be put into neutral broth and incubated for about a week a large excess of staphylococcus will be present , after two weeks or more the numbers of cocci and bacilli will be more or less in equal proportion , in the course of a further week or two the bacilli may come to outnumber the cocci, although the amount of growth will not in any case be very great If on the other hand the comedo starts with a relatively large proportion of staphylococci present it is probable that under the conditions just mentioned the acne bacillus will make practically no growth at all By the method to be described it is rarely that one fails to obtain a considerable growth of the acne bacillus within a period of from 10 to 14 days In the case of a comedo containing a large excess of bacilli a culture practically pure and sufficiently abundant for the preparation of a vaccine may often be obtained by the fifth or sixth day

In the preparation of some 20 autogenous vaccines by the author s method he has only failed once to obtain a satisfactory growth of the acne bacillus On this occasion a large atypical staphylococcus apparently was able to adapt itself to the altered cultural conditions , it started to grow on about the sixth day and in the course of another week it had completely overgrown the acne bacillus Subcultured on to agar this organism failed to grow under either aerobic or anaerobic conditions

The method of culture —The culture method consists merely in growing the organism in a tube of neutral broth the surface of which has been covered with about half an inch of sterile olive oil or so called ordinary lard In particular method has a similar effect on man under these circumstances In some instances moreover, this dormant power of the specific resistance may be awakened by sensitised vaccine even at a comparatively late stage in the attack In cases in which the treatment did no good there was no evidence to show that it did the slightest harm

A PRACTICAL METHOD OF GROWING THE ACNE BACILLUS FROM THE COMEDO

FOR THE PREPARATION OF VACCINES

BY T H C BENIANS, M R C S ENG , L R C P LOND ,
JUNIOR ASSISTANT, INOCULATION DEPARTMENT, LONDON HOSPITAL

(*From the Bacteriological Department London Hospital Medical College* Professor W BULLOCH F R S , *Director*)

NO attempt is made to enter at length into the controversial topic of the etiology of the disease The relationship of the staphylococcus and acne bacillus as causative agents of the various lesions coming under the head of acne vulgaris is still to some extent unsettled In passing, however the writer gives it as his opinion that judging on present evidence the acne bacillus is the agent chiefly concerned in the immediate production of the skin lesions Among these very protean lesions some are from their anatomical position completely beyond the scope of vaccine therapy , in others the conditions are ideal for attaining the best results by this method of treatment

It is taken that the position of vaccines in the treatment of this disease although not entirely satisfactory, is yet sufficiently well established , the question now remains as to the relative values of autogenous as compared with stock vaccines As a general rule at any rate in hospital practice it is customary to use a stock vaccine so that this question has probably not yet been sufficiently well tested In staphylococcal lesions we know that occasionally an autogenous vaccine may effect a cure where a stock vaccine has failed and this although we are unable to differentiate varied strains of staphylococcus aureus In the case of the acne lesions we have some evidence already that the organisms found in the lesions belong to a large and varied group of bacilli

In a number of cases under treatment by the author the patients were changed from treatment with a stock acne vaccine to an autogenous vaccine with very beneficial results , in some cases a complete cure of the pustular lesions was quickly effected Data by other workers on this subject are however, needed because no more direct proof than a general consensus of opinion is possible It may well be that some or many of the numerous failures in the treatment of acne by vaccines are to be attributed to the use of a stock vaccine, which vaccine may have been prepared from an organism totally different in its characters from that growing on and in the patient s skin

Although the cultural characteristics of the acne bacillus are now fairly well known the preparation of an autogenous vaccine for a patient remains still a matter of considerable difficulty The principal methods of isolation and culture so far published are those described by Fleming[1] and by Sudmerson and Thompson[2] Fleming advocated the use of an oleic acid agar , he obtained the material from the smaller pustules, and grew it in the first instance anaerobically The latter-named writers use an acid serum agar , they take the deeper parts of the comedo in which the acne bacillus usually predominates, emulsify this in saline, and spread thinly on the slope, so that they may obtain isolated colonies to pick off They also made the first cultures anaerobically Most workers however, agree that to enable the acne bacillus to start growing on artificial media a considerable mass of the infective material must be planted, even on a medium which is favourable to the growth of the organism When this is done it mostly happens that there are sufficient staphylococci present to overgrow the more slowly growing acne bacillus

The method used by the writer does not aim at producing the organism in a state of bacteriological purity The aim of the procedure is to supply in a reasonably short time a sufficiently free growth of the acne bacillus for the purpose of preparing a vaccine In the more complete methods, moreover the bacteriologist must himself remove the pus, or the comedo, from the patient and at once proceed to select the required parts of it and to plant them out under anaerobic conditions By the simple method here described the bacteriologist requires merely one or two comedones, whether expressed a few minutes or days before is immaterial

As will be seen, a very small proportion of staphylococci are almost invariably present but these may be treated as a negligible factor The proportion of staphylococci present is not more than about 10 per cent at the most, thus in giving an average dose of the acne vaccine say 5 000 000, one is giving at the same time 500 000 staphylococci Since an average dose of the staphylococci, perhaps to be given at the same time with the acne is not likely to be less than 250 000 000 the original 500,000 contained in the acne vaccine may well be overlooked

Variations in the bacteriology of the comedo —The bacteriology of the comedo varies greatly from a quantitative point of view Almost always both staphylococci and acne bacilli are present The staphylococcus may be said to be invariably present , the acne bacillus is sometimes though rarely absent The average sebaceous plug contains acne bacilli greatly in excess of the staphylococci which latter are mainly present in the superficial part If such a comedo be put into neutral broth and incubated for about a week a large excess of staphylococcus will be present , after two weeks or more the numbers of cocci and bacilli will be more or less in equal proportion , in the course of a further week or two the bacilli may come to outnumber the cocci, although the amount of growth will not in any case be very great If on the other hand the comedo starts with a relatively large proportion of staphylococci present it is probable that under the conditions just mentioned the acne bacillus will make practically no growth at all By the method to be described it is rarely that one fails to obtain a considerable growth of the acne bacillus within a period of from 10 to 14 days In the case of a comedo containing a large excess of bacilli a culture practically pure and sufficiently abundant for the preparation of a vaccine may often be obtained by the fifth or sixth day

In the preparation of some 20 autogenous vaccines by the author s method he has only failed once to obtain a satisfactory growth of the acne bacillus On this occasion a large atypical staphylococcus apparently was able to adapt itself to the altered cultural conditions , it started to grow on about the sixth day and in the course of another week it had completely overgrown the acne bacillus Subcultured on to agar this organism failed to grow under either aerobic or anaerobic conditions

The method of culture —The culture method consists merely in growing the organism in a tube of neutral broth the surface of which has been covered with about half an inch of sterile olive oil or so-called ordinary lard In practice a urine can be obtained in patients suffering from malarial fever even when the malarial parasites are absent from the peripheral blood.

[2] Journal of Pathology and Bacteriology vol xiv 1909 p 224

As is well known, the high colour of urine in malaria depends upon the increased amount of urobilin present. Plehn, in 1909, recommended this very delicate and simple reaction to demonstrate the presence of urobilin in the urine. To obtain it we require the following: 1. Schlesinger's solution, which consists of zinc acetate, 1 part; alcohol, 10 parts. 2. Tincture of iodine. 3. A sample of the urine to be tested.

In a test tube one-third filled with the unfiltered urine an equal quantity of Schlesinger's solution, which has previously been well shaken, is added. A few drops of a weak solution of tincture of iodine are now added, as this accelerates the reaction. The mixture is then filtered, and if urobilin be present the filtered mixture shows a more or less distinct fluorescence. This reaction is met with in the urine of patients suffering from all types of malarial fever To show how delicate it is, in cases of malignant malaria it can be obtained after diluting the urine with 200 parts of water. Quite healthy urine does not give the reaction, as it contains, if any, only the slightest amount of urobilin. Urobilin is present, of course, in many other diseases, such as cirrhosis of the liver, liver abscess, many infectious diseases, &c.

This test was used frequently in the Government Civil and Victoria Hospitals, Hong-Kong, and we found it useful, particularly in diagnosing doubtful cases where parasites were not present in the blood. Now and then a case of malarial fever may happen in which the hepatitis and hæmolysis are not sufficient to cause urobilinuria. The absence of this reaction, however, speaks strongly against acute malarial fever, a fact of great value when a quick diagnosis is to be made.

NOTE OF A CASE OF AMŒBIC DYSENTERY OF THREE AND A HALF YEARS' DURATION RAPIDLY CURED BY INJECTIONS OF EMETINE HYDROCHLORIDE.

BY FERNAND L DE VERTEUIL, M.D. EDIN., M.R.C.S. ENG., L.R.C.P. LOND.,

SURGEON, R.N. (RETIRED).

THE following case is of interest as showing the rapid, nay immediate, effect of emetine in a severe chronic case of amœbic dysentery.

The patient, a Frenchman, aged 44, first came to consult me on May 5th, 1913. He gave the following history. In October, 1909, he left France for Panama, where he was to represent an important French firm. Previous to this he had always enjoyed excellent health, and was a strong, powerfully built man. Two months after his arrival in Panama he suffered from a sharp attack of dysentery with passage of mucus and bloody stools. From Jan. 1st to April, 1910, he was constantly ill, suffering from fever and diarrhœa. Besides various other drugs he was dosed with quinine. As he was rapidly going downhill he was advised by Dr. Preciado, of the Panama Presidency, to leave immediately for France. During the last [illegible] 30lb in weight. [illegible] he was operated [illegible] months after this operation he felt fairly well. This [illegible] was, however, of short duration, [illegible] to return to a normal diet he had a recurrence of his dysenteric symptoms, and had to confine himself to a strict milk diet. During the following two and a half years he had six severe subacute attacks. These attacks would last for several weeks. Two of them were followed by liver abscess, for which he underwent two further operations.

In April, 1913, the patient arrived in Vancouver. Shortly after his arrival here he had a subacute attack, and it was for this he came to consult me. He had an urgent and constant desire to go to stool; he was passing from 20 to 30 stools daily, the majority of which consisted of only a little mucus and blood, accompanied [illegible] tenesmus. There were pain a[illegible] of the colon. He had a slight [illegible] He also suffered from external hæmorrhoids, which had apparently been caused by the constant straining at stool. The patient appeared a complete nervous and physical wreck; he was thin and emaciated, with a muddy, icteric-looking complexion, prominent cheek bones, with sunken eyeballs. The marvellous results first obtained and published by Leonard Rogers,[1] and subsequently by others,[2] with emetine made me anxious to try it. Five days, however, elapsed before I could obtain a supply of the drug. Late in the evening of May 10th the patient received his first injection, consisting of 1/3 gr. of emetine hydrochloride dissolved in saline solution and enclosed in a glass ampoule (Burroughs and Wellcome). On the following day at *noon* he received a second injection. During the night of the 11th he had no call to stool; previously he had to get up seven or eight times during the night. On the 12th, *36 hours* after the first injection, he received a third injection, and from that date there was a complete disappearance of all dysenteric symptoms. That day he had but one stool, which was quite normal in appearance. He subsequently received seven more injections as a matter of precaution. During the time he was receiving the emetine injections no other drug or treatment was used. The injection of the drug did not cause the slightest unpleasant sign or symptom.

It is barely three weeks (May 29th) since the patient received his first injection, yet the mental and physical change that has already occurred is remarkable. As the patient graphically states, "it was like passing suddenly from Hades to Olympus." He is gradually resuming a normal diet. In fact, on May 17th, a week after he had began the injections, he could not resist the temptation and consumed a large steak. This did not cause the slightest inconvenience, though previously such a dietary indiscretion would have been followed by the most dire results.

It is as yet much t o early to speak of a permenant cure in this case. The results obtained have, however, appeared to me to be so extraordinarily rapid that I have not hesitated to describe the case in some detail. We have few specific drugs in medicine. The addition of a new one is certainly an epoch-marking discovery. Emetine seems to be as potent a specific in amœbic dysentery as quinine is in malaria or salvarsan in syphilis and yaws. When we consider the dangers and fatal complications of this malady, as well as the years of misery and suffering which on account of its chronicity and liability to recurrence it often entails, Major Leonard Rogers's great discovery must occupy a foremost place in the medical achievements of the present century.

Vancouver.

A Manual of Operative Surgery By H J WARING, M S , M B , B Sc Lond , F R C S Eng , Surgeon to, and Joint Lecturer in Surgery at, St Bartholomew's Hospital Fourth edition London Henry Frowde and Hodder and Stoughton 1912 Pp 778 Price 12*s* 6*d* net

IN any book of operative surgery it is very necessary that from time to time those operations which are no longer practised should be removed from the text and new operations added, and great judgment is required as to which operations should be discarded These necessary changes have been made in the fourth edition of this well known book, and the work has been brought thoroughly up to date It is hardly necessary to say that it is a valuable text book for the student and one on which he can rely—opinion to this effect has been so completely endorsed

There is one change in this edition which deserves more than a passing mention The author has thought it well to employ throughout the "Basle nomenclature" of anatomy and we acknowledge that there are many weighty reasons why this should be done In Canada and the United States and also in Australia, the Basle nomenclature is much more widely used than in this country, and a text book which has so wide a circulation as this is required by many of its readers to contain the new anatomical terms, but this is almost the first surgical work in this country to introduce the new nomenclature There is much to be said for the new names, but many surgeons doubt if they will ever become universally employed Moreover, the Basle nomenclature needs revision, and many of its absurdities will, we think, have to be removed before it will be received by British surgeons A compromise might at present be effected by employing both the new and the old terms, placing one or the other in brackets, though considerable trouble to authors would thus be caused

Diseases of the Stomach Intestines, and Pancreas By ROBERT COLEMAN KEMP, M D Professor of Gastro intestinal Diseases in the New York School of Clinical Medicine Second edition London and Philadelphia W B Saunders Company 1912 Pp 1021 Price 28*s*

THIS volume contains a full and complete account of diseases of the stomach, intestines, and pancreas, special stress being laid on methods of diagnosis and treatment

The first portion of the work is occupied with a discussion on the anatomy and physiology of the stomach and intestines hints on the interrogation of the patient and a review of the general methods of physical examination In the second portion detailed descriptions are given of diseases of the stomach In the chapter on diet Dr Kemp discourses at length on Professor R H Chittenden's views as to the danger of excessive protein diet Professor Chittenden maintains that the standards of diet usually recommended are excessive in quantity in regard to proteins He states that they do not undergo complete oxidation in the body like non nitrogenous foods, but that there is left behind a residue of non combustible matter, crystalline nitrogenous products, which ultimately, if occurring in excess of the requirements of the body, prove injurious to the gastro intestinal tract, liver, kidneys and to the circulatory and nervous system In accordance with these views Dr Kemp lays down a dietary containing an excess of vegetable food, but he does not appear to adhere closely to the restricted dietary recommended by Professor Chittenden, although he is convinced of the soundness of his views The clinical descriptions throughout the work

A Manual of Operative Surgery By H J WARING, M S, M B, B Sc Lond, F R C S Eng, Surgeon to, and Joint Lecturer in Surgery at, St Bartholomew's Hospital Fourth edition London Henry Frowde and Hodder and Stoughton 1912 Pp 778 Price 12*s* 6*d* net

IN any book of operative surgery it is very necessary that from time to time those operations which are no longer practised should be removed from the text and new operations added, and great judgment is required as to which operations should be discarded These necessary changes have been made in the fourth edition of this well known book, and the work has been brought thoroughly up to date It is hardly necessary to say that it is a valuable text book for the student and one on which he can rely—opinion to this effect has been so completely endorsed

There is one change in this edition which deserves more than a passing mention The author has thought it well to employ throughout the "Basle nomenclature" of anatomy and we acknowledge that there are many weighty reasons why this should be done In Canada and the United States and also in Australia, the Basle nomenclature is much more widely used than in this country, and a text book which has so wide a circulation as this is required by many of its readers to contain the new anatomical terms, but this is almost the first surgical work in this country to introduce the new nomenclature There is much to be said for the new names, but many surgeons doubt if they will ever become universally employed Moreover, the Basle nomenclature needs revision, and many of its absurdities will, we think, have to be removed before it will be received by British surgeons A compromise might at present be effected by employing both the new and the old terms, placing one or the other in brackets, though considerable trouble to authors would thus be caused

Diseases of the Stomach Intestines, and Pancreas By ROBERT COLEMAN KEMP, M D Professor of Gastro intestinal Diseases in the New York School of Clinical Medicine Second edition London and Philadelphia W B Saunders Company 1912 Pp 1021 Price 28*s*

THIS volume contains a full and complete account of diseases of the stomach, intestines, and pancreas, special stress being laid on methods of diagnosis and treatment

The first portion of the work is occupied with a discussion on the anatomy and physiology of the stomach and intestines hints on the interrogation of the patient and a review of the general methods of physical examination In the second portion detailed descriptions are given of diseases of the stomach In the chapter on diet Dr Kemp discourses at length on Professor R H Chittenden's views as to the danger of excessive protein diet Professor Chittenden maintains that the standards of diet usually recommended are excessive in quantity in regard to proteins He states that they do not undergo complete oxidation in the body like non nitrogenous foods, but that there is left behind a residue of non combustible matter, crystalline nitrogenous products, which ultimately, if occurring in excess of the requirements of the body, prove injurious to the gastro intestinal tract, liver, kidneys and to the circulatory and nervous system In accordance with these views Dr Kemp lays down a dietary containing an excess of vegetable food, but he does not appear to adhere closely to the restricted dietary recommended by Professor Chittenden, although he is convinced of the soundness of his views The clinical descriptions throughout the work to be particularly interesting to otologists as well as to pathologists generally. Dr. Alex Wallgrew gives a careful account of the clinical and pathological phenomena observed in what he calls Heine-Medin disease, which in reality is poliomyelitis anterior acuta. In 1911 a more or less disseminated epidemic of this disease appeared in Finland. This paper is also illustrated by excellent plates, and extends to 40 pages. It is well worth perusing. Acute Myelitis and So-called Spontaneous Hæmatomyelia forms a contribution by H. Fabritius. He gives a full account of the symptoms and diagnosis of myelitis, and rejects the term "spinal thrombosis" suggested by Bastian. The final contributions are on Two Cases of Extradural Intravertebral Tumours, by A. J. Palmin, and A Case of Right-sided So-called Sclerotic Atrophy of the Brain, by H. Fabritius.

Pathologists specially interested in the nervous system will welcome these careful and elaborate investigations, and we look forward to the appearance of the next volume. Meantime we congratulate Professor Homén on the merits as well as the get-up of his "New Series" of original contributions.

Contribution à l'Étude du Traitement du Cancer du Testicule. Par le Docteur C. OSOIRO MASCARENHAS, Ancien Interne des Hôpitaux de Paris. Paris: Société Générale d'Imprimerie et d'Édition Levé. 1912. Pp. 223.

THIS is a graduation thesis, and the author has chosen a subject full of importance in surgery. The results of removal of cancer of the testis have been in many cases very bad, for the operation was usually confined to excision of the testis, and it is only in recent years that any careful study has been made of the causes of these unsatisfactory results. The modes of dissemination of the new growth should dictate the treatment. Kocher was the first in 1885 to attempt to remove by the transperitoneal route the lumbar glands so as to prevent recurrence. Villar was the first to suggest a long curved incision so as to reach the glands extraperitoneally, and this method has been followed by others. More lately there has been a return to the transperitoneal route. The object of the author's pamphlet is to determine in which cases a mere removal of the testis is sufficient, and which need the more elaborate and severe operation. It is true that the late results of simple removal of the testis are very doubtful, but it is certain that there are indubitable cases of cure after this operation. The lymphatic glands connected with the testis are very widely spread along the inferior vena cava and the abdominal aorta, and some are situated even behind these vessels. The author has investigated a large number of cases; and he has come to the conclusion that if the cord is definitely thickened it is practically certain that the lumbar lymphatic glands are enlarged, but it cannot be said that the absence of thickening of the cord is any definite proof that the lymphatic glands are not involved. When the glands are enlarged they should be removed, but he considers that the introduction of this operation is still too recent to allow the expression of a definite opinion of its real value. The work has evidently required a good deal of investigation, and it has been thoroughly done.

A Text-book on the Practice of Gynecology. For Practitioners and Students. By W. EASTERLY ASHTON, M.D., LL.D., *Professor of Gynecology in the Medico-Chirurgical College of Philadelphia.* Fifth edition. With 1050 original line drawings. London and Philadelphia: W. B. Saunders Company. 1912. Pp. 1100. Price 27*s.* 6*d.* net.

THIS book has passed through five editions and five reprints in seven years, and we must confess we are surprised. In this edition the author states that the revision has been very thorough and that every effort has been made to bring the work up to date. On turning to the description of the operative treatment of cancer of the cervix we find that total extirpation of the uterus and the removal of a portion of the surrounding healthy tissue is recommended. On looking up the description of the operation of total hysterectomy we find an ordinary total hysterectomy described, and not a word said about the extended abdominal or Wertheim's operation. Again, it is recommended, when a complete hysterectomy is performed for malignant disease, that the operation should be immediately preceded by the removal of the cancerous tissue in the cervix and the closure of the cervical canal by a continuous silk suture. We wonder in how many cases the author himself has carried out this practically impossible procedure. Following this incomplete account of total hysterectomy for malignant disease there are seven and a half pages devoted to the old-fashioned operation of vaginal hysterectomy with the use of clamps. As we said in our review of the last edition, this work contains very little pathology. The book, however, includes a large amount of information, and the whole forms a bulky volume of 1100 pages, and when we consider into what a comparatively small compass many authors find it possible to compress all the important facts of gynæcology and yet to leave out nothing that is really worth inclusion, we wonder how the author manages to occupy so much space. There are, it is true, some 1050 line drawings illustrating the text, but when we note that such things as a tin sitz bath, an enamelled steel jug, an enamelled steel bowl, and many similar articles are illustrated the large number of the illustrations is accounted for. Yet in spite of their number very few of the drawings are remarkable either for their artistic value or for the information they give; the great majority are diagrams of little value. But somebody apparently reads the book, though it is not a work that we can conscientiously recommend to English students, seeing that there are so many much better and cheaper works to be obtained.

Handbuch der Vergleichenden Physiologie. Herausgegeben von HANS WINTERSTEIN. Lieferungen 32–33. *Physiologie des Energiewechsels.* Erste Hälfte. Pp. 645–806; pp. 807–968. Jena: Gustav Fischer. 1913. Price 5 marks each.

IN these two Lieferungen Professor Biedermann continues his exposition of the supporting and skeletal substances, and as he has taken the whole animal kingdom for his subject it is easy to see how comprehensive must be the details set forth. At the beginning of No. 32 the author finishes what he has to say about the corals, and then proceeds to consider the skeletal tissues of the mollusca, including the lamellibranchs, gasteropods, and brachiopods. The author devotes a considerable space to the interesting question of the formation of pearls by certain bivalves, and gives prominence more especially to the recent work of Rubbel on "Pearl Formation in Margaritana"; nor does he omit the work of R. Dubois and also of the English observers—Jameson, Herdman, and Hornell.

In No. 33, first the cuticular structure of worms and arthropods is dealt with, and, in fact, it occupies the greater part of the text. A very full account of chitin—a word coined in 1823 by Odier—in its structural, chemical, optical, physical, developmental, and physiological relations in different species is given, including its extraordinary resistance to solvents. The calcification of the exo-skeleton of the crustacea is then considered, followed by the secretion of chitin, and the question of the casting and regeneration of a new "skin." The development of the radula, or ribband-like tongue, and its series of teeth is very fully described. From this it is an easy transition to the development of the scales on the wings or other parts of butterflies and moths. Oddly enough, in the literature we failed to find a reference to the work of George Rainey on shell formation. The mantles of tunicates come next, with their N-free cellulose-like constituents first described to be particularly interesting to otologists as well as to pathologists generally. Dr. Alex Wallgrew gives a careful account of the clinical and pathological phenomena observed in what he calls Heine-Medin disease, which in reality is poliomyelitis anterior acuta. In 1911 a more or less disseminated epidemic of this disease appeared in Finland. This paper is also illustrated by excellent plates, and extends to 40 pages. It is well worth perusing. The calcification of the exo-skeleton of the crustacea is then considered, followed by the secretion of chitin, and the question of the casting and regeneration of a new "skin." The development of the radula, or ribband-like tongue, and its series of teeth is very fully described. From this it is an easy transition to the development of the scales on the wings or other parts of butterflies and moths. Oddly enough, in the literature we failed to find a reference to the work of George Rainey on shell formation. The mantles of tunicates come next, with their N-free cellulose-like constituents first described each subject the conductors of the Library have sought the advice of a recognised authority, so that the books may have a special hall mark and comprise the essentials of the subject —both the things which are admitted on all hands, and the arguments which by suggesting that more than one construction can be put upon the facts, point the way for further research The object of the conductors of the Library moreover, is to treat of each subject in such a way that not only shall nothing obsolete find notice but that the relationships of contemporary thought shall be brought out, which is to propose that the volumes of the Library, though written by independent authors, shall be to a certain extent dependent upon one another, their contents all having a bearing on life as it is

Mr Snowden's definitions of Socialism and Syndicalism are clear, and form a good preface to the whole series His history of the rise of Socialism is well done, and his criticisms of the theories of St Simons Fourier, Louis Blanc, Robert Owen, Karl Marx, and Lassalle are acute as well as fair His statement that Socialism will come only when the great body of men and women have become intellectually convinced that they cannot promote their own welfare save by promoting the common welfare is one which we must all welcome The admission that there is a practical reason as well as a moral reason against advancing Socialism by a class war is a concession to the intelligence of wage earners—it is the point of view, we believe, that William Morris, the most important English Socialist, took at the end of his career Mr Snowden's book is full of similar plain and moderate statements, but a Socialism that does not aim at the abolition of private property, and only seeks to socialise such property as can be more efficiently and economically controlled socially, will surely not satisfy the leaders of Socialism

Mr W V Osborne's book on the objects and meaning of sane trade unionism has the same merits of clearness and moderation It is usual to begin the story of trade unionism with the famous case of the Dorsetshire labourers, but, as a matter of fact, combinations among workmen for the raising of wages had existed many years before 1835 But the case of the Dorsetshire labourers was among the first to focus public opinion on the matter, and it has a particular interest for this journal, for the Founder of THE LANCET, a Dorsetshire man and then Member of Parliament for Finsbury, made his reputation in the House of Commons by his outspoken speech upon the arrest and sentence of those luckless hinds They had taken a part in endeavouring to form an agricultural labourers' movement they were arrested and tried for the crime of administering an unlawful oath and, notwithstanding their ignorance of having committed an offence, were found guilty and sentenced to seven years' transportation Wakley's speech ended with an address to the King (William IV) that His Majesty would be pleased to grant a pardon and that the six labourers convicted at Dorchester in 1833 should be recalled Joseph Hume was his co teller, and 84 voted with Wakley and 310 against But on March 19th, 1836, Wakley, who with the assistance of Hume and O Connell had kept the terrible story before the public, was able to elicit from Lord John Russell a reply to the effect that the convicted had received a free pardon and were returning to their native village at the Government's expense Mr Osborne, who is the hero of the Osborne judgment, describes in a very simple and straightforward manner the early struggles of trade unionism for a legal status, the constitution and development of trade unionism and the policy and programme of the Labour party as it now exists His general conclusion is that properly conducted trade unions will never find themselves unnecessary, but that if the unions refuse to advance with the times and adapt themselves to changing conditions they must sink to decay His chapter on Syndicalism may well be read side by side with Mr Snowden's chapter on Syndicalism and the Social Movement

Mr W H Dawson, writing on "Industrial Germany," supplies many of the kind of details which those who desire to apply the principles advocated in the two previous books would want to have It is especially necessary for the proper comprehension of industrial developments in this country that we should understand how far in Germany the railways and waterways, for example, have been brought into a state of efficiency and made to administer to the interests of commerce owing to their national ownership Similarly, Mr James Long's description of the small holdings movement is full of lessons for those who see the waste of our land, and who know that agricultural employment, including under that word dairy farming, keeping of live stock, market gardening fruit and flower growing, would in proper economical conditions provide reasonable remuneration in a healthy environment for thousands now undergoing the miseries of overcrowding and underfeeding

The other two volumes of the series are more directly of interest for medical men, although the repopulation of the countryside would probably be one of the greatest factors imaginable in the promotion of public health We pass now from discussing the conditions for the betterment of populations by a more equitable division of advantages and opportunities to the consideration of the circumstances which should improve the health and capacity of the individual for enjoying that betterment Dr Edgar Schuster has written an extremely able and clear account of the problems which lie before the eugenist He puts out the claim for eugenics to be reckoned as a science which has already placed many facts inferences, and hypotheses in orderly array, systematising "the study of those agencies under social control which may improve or impair the racial qualities of future generations either physically or mentally," such being Galton's definition of eugenics The book explains briefly the theories of organic evolution and the principles of Mendelism, and describes also the statistical methods useful for the study of inheritance A chapter on the hereditary nature of certain diseases is properly cautious, inasmuch as modern scientific opinion is not at all in accord with the views of even 20 years ago Tuberculosis, once considered to be entirely hereditary, would now be held by many persons not to be hereditary at all , on the other hand, direct inheritance undoubtedly plays a great part in feeble mindedness, and certain nervous diseases appear to conform to Mendelian laws

The great object of eugenics is to influence the unborn nature of man rather than to improve the external conditions of the living The central thought that is presented in Mr Thiselton Mark's "Modern Views of Education" is that whether in organisation or in teaching it is fundamentally necessary to construct and build around the life that is already there, and his manual thus has with Dr Schuster s a common message The actual problems that affect medical education are not touched upon in a work that has to be at the same time small in bulk and general in scope, but we are certain that the particular difficulties which confront the General Medical Council will be better appreciated by those who have made themselves, through the medium of Mr Mark's pages, familiar with the general direction of modern educational thought This book is really too brief

---

DEATH OF A CENTENARIAN —The death occurred at Horsebridge, Hellingly, Sussex, on June 18th, of Mrs Sarah Ann Akehurst, who on May 21st celebrated her 101st birthday each subject the conductors of the Library have sought the advice of a recognised authority, so that the books may have a special hall mark and comprise the essentials of the subject—both the things which are admitted on all hands, and the arguments which by suggesting that more than one construction can be put upon the facts, point the way for further research The object of the conductors of the Library moreover, is to treat of each subject in such a way that not only shall nothing obsolete find notice but that the relationships of contemporary thought shall be brought out, which is to propose that the volumes of the Library, though written by independent authors, shall be to a certain extent dependent upon one another, their contents all having a bearing on life as it is

DEATH OF A CENTENARIAN —The death occurred at Horsebridge, Hellingly, Sussex, on June 18th, of Mrs Sarah Ann Akehurst, who on May 21st celebrated her 101st birthday which, we know to be large, but the measure of which *escapes us in existing conditions, and assist us to formulate* a scheme of control now that our weapons are more effective. Sir MALCOLM MORRIS insists that before any systematic control of syphilis can be secured notification is necessary, and it must be remembered that the National Insurance Act provides already a half measure of this kind. He would not have the licensing of prostitutes made any part of such a scheme, and the experience of foreign countries now points in the same direction.

Eddowes and Others *v.* The St. John's Hospital for Diseases of the Skin.

THE action brought recently by three of its former honorary medical officers against the corporation known as the St. John's Hospital for Diseases of the Skin is of a nature fortunately of rare occurrence in the law courts, and the absence of precedent was responsible for the evident hesitancy of Mr. Justice PICKFORD with regard to some of the issues raised and the remedies sought for. Dr. A. EDDOWES, Mr. G. W. DAWSON, and Dr. L. F. KNUTHSEN, the three plaintiffs who, supported with success by the London and Counties Medical Protection Society, raised in the King's Bench Division the question whether the committee of the hospital had exercised towards them powers which in law it possessed, were not the only persons interested directly and indirectly in the points discussed. Four other members of the staff of the hospital had shared their dismissal upon similar alleged grounds, while the whole medical profession was concerned, if less immediately no less vitally, in the upholding of the plaintiffs' broad contentions. With the actual matters which brought a large number of the medical staff of a particular institution into conflict with its board of management we do not propose to deal. There was obvious disagreement between them and one of their colleagues. The fact that there was long-standing friction of a very serious nature between Dr. MORGAN DOCKRELL and certain of his fellow practitioners was made public property at the trial, as was the fact that the committee which inquired into the matter adopted Dr. DOCKRELL's view and gave effect to it in a manner which added emphasis to its finding and, indeed, rendered litigation almost inevitable. The procedure by which the committee arrived at its conclusion to dispense with the services of the plaintiffs was one of the points to which attention was called by the plaintiffs at the trial, but the fact that they had been dismissed by notice from their posts as members of the honorary staff of the hospital was the principal issue raised on their behalf, and the point to which Mr. Justice PICKFORD mainly directed his judgment. In delivering it he cleared the ground of other questions by pointing out that he had not got to decide whether the defendants acted *bonâ fide* or whether they purported to exercise their powers to the best interests of the corporation. There was not, in short, any allegation of bad faith or corrupt intention made against the governing body. The question upon which the learned judge concentrated his attention was whether the committee had acted within its legal powers, and on that point he was against it. He did not find in the articles of association or the rules of the hospital, or in the general principles applicable, anything that would justify dismissal in the circumstances proved to exist. Mr. Justice PICKFORD further made a declaration that the plaintiffs were entitled to remain members of the corporation, but refused an injunction, which they asked for, to restrain the defendants from excluding them from the hospital. It was on these grounds that judgment was given for the plaintiffs for sums of £50—damages of a nominal character awarded in the absence of any evidence of pecuniary loss upon which accurate assessment of compensation could be made—and for costs. Upon this result congratulation is due to the plaintiffs and to the colleagues who shared their dismissal at the hands of the defendants.

What is the position of a member of the staff of a hospital in the event of questions arising of a serious nature as to which he finds himself in disagreement with the board of management? The action against the governing body of the St. John's Hospital for Diseases of the Skin has called attention to the desirability of the position of the staffs of hospitals being defined before their appointment in terms capable of covering all circumstances which are reasonably likely to occur; their mutual relations and their relations with the lay authorities should be made the subject of a written contract at the time when the appointment is entered upon. In the case of the St. John's Hospital for Diseases of the Skin there was a complication arising out of the peculiar constitution of the corporation owning the hospital, and its governors in good faith adopted a position as to which they were held by the learned judge to have been mistaken. Mr. A. W. WEST, treasurer of St. George's Hospital, and Sir THOMAS BARLOW, President of the Royal College of Physicians of London, were called on behalf of Dr. EDDOWES and his co-plaintiffs to explain what should be the status of a member of the staff of the hospital in the absence of definite regulation by contract. Neither of these undoubted authorities, approaching the question from separate points of view, had any doubt as to the permanence of the appointment of physician on the staff of a hospital in the absence of conditions as to surrender at a stated age or after a stated period. Limitation in point of time of the tenure of these posts is now more common, but that such a tenure could not be determinable by notice was the gist of Sir THOMAS BARLOW's evidence upon this head. Naturally he admitted that misconduct would justify dismissal; but this, he pointed out, should only take place after proper inquiry, and there should be a tribunal of arbitration for the settlement of disputes between opposing sections of the staff if there should be any disagreement to justify such intervention. The desirability of arbitration of an independent character does not appear to have occurred to the committee of the St. John's Hospital for Diseases of the Skin, the members of which failed to recognise that, owing to the position occupied by Dr. DOCKRELL and other matters, they were not the right persons to adjudicate upon what amounted to a dispute between themselves and the plaintiffs. In addition to this, one of their number, who took the chair at their meetings, appears to have increased rather than diminished the friction which, we know to be large, but the measure of which *escapes us in existing conditions, and assist us to formulate* a scheme of control now that our weapons are more effective. Sir MALCOLM MORRIS insists that before any systematic control of syphilis can be secured notification is necessary, and it must be remembered that the National Insurance Act provides already a half measure of this kind. He would not have the licensing of prostitutes made any part of such a scheme, and the experience of foreign countries now points in the same direction.

◆

Eddowes and Others v. The St. John's Hospital for Diseases of the Skin.

THE action brought recently by three of its former honorary medical officers against the corporation known as the St. John's Hospital for Diseases of the Skin is of a nature fortunately of rare occurrence in the law courts, and the absence of precedent was responsible for the evident hesitancy of Mr. Justice PICKFORD with regard to some of the issues raised and the remedies sought for. Dr. A. EDDOWES, Mr. G. W. DAWSON, and Dr. L. F. KNUTHSEN, the three plaintiffs who, supported with success by the London and Counties Medical Protection Society, raised in the King's Bench Division the question whether the committee of the hospital had exercised towards them powers which in law it possessed, were not the only persons interested directly and indirectly in the points discussed. Four other members of the staff of the hospital had shared their dismissal upon similar alleged grounds, while the whole medical profession was concerned, if less immediately no less vitally, in the upholding of the plaintiffs' broad contentions. With the actual matters which brought a large number of the medical staff of a particular institution into conflict with its board of management we do not propose to deal. There was obvious disagreement between them and one of their colleagues. The fact that there was long-standing friction of a very serious nature between Dr. MORGAN DOCKRELL and certain of his fellow practitioners was made public property at the trial, as was the fact that the committee which inquired into the matter adopted Dr. DOCKRELL's view and gave effect to it in a manner which added emphasis to its finding and, indeed, rendered litigation almost inevitable. The procedure by which the committee arrived at its conclusion to dispense with the services of the plaintiffs was one of the points to which attention was called by the plaintiffs at the trial, but the fact that they had been dismissed by notice from their posts as members of the honorary staff of the hospital was the principal issue raised on their behalf, and the point to which Mr. Justice PICKFORD mainly directed his judgment. In delivering it he cleared the ground of other questions by pointing out that he had not got to decide whether the defendants acted *bonâ fide* or whether they purported to exercise their powers to the best interests of the corporation. There was not, in short, any allegation of bad faith or corrupt intention made against the governing body. The question upon which the learned judge concentrated his attention was whether the committee had acted within its legal powers, and on that point he was against it. He did not find in the articles of association or the rules of the hospital, or in the general principles applicable, anything that would justify dismissal in the circumstances proved to exist. Mr. Justice PICKFORD further made a declaration that the plaintiffs were entitled to remain members of the corporation, but refused an injunction, which they asked for, to restrain the defendants from excluding them from the hospital. It was on these grounds that judgment was given for the plaintiffs for sums of £50—damages of a nominal character awarded in the absence of any evidence of pecuniary loss upon which accurate assessment of compensation could be made—and for costs. Upon this result congratulation is due to the plaintiffs and to the colleagues who shared their dismissal at the hands of the defendants.

What is the position of a member of the staff of a hospital in the event of questions arising of a serious nature as to which he finds himself in disagreement with the board of management? The action against the governing body of the St. John's Hospital for Diseases of the Skin has called attention to the desirability of the position of the staffs of hospitals being defined before their appointment in terms capable of covering all circumstances which are reasonably likely to occur; their mutual relations and their relations with the lay authorities should be made the subject of a written contract at the time when the appointment is entered upon. In the case of the St. John's Hospital for Diseases of the Skin there was a complication arising out of the peculiar constitution of the corporation owning the hospital, and its governors in good faith adopted a position as to which they were held by the learned judge to have been mistaken. Mr. A. W. WEST, treasurer of St. George's Hospital, and Sir THOMAS BARLOW, President of the Royal College of Physicians of London, were called on behalf of Dr. EDDOWES and his co-plaintiffs to explain what should be the status of a member of the staff of the hospital in the absence of definite regulation by contract. Neither of these undoubted authorities, approaching the question from separate points of view, had any doubt as to the permanence of the appointment of physician on the staff of a hospital in the absence of conditions as to surrender at a stated age or after a stated period. Limitation in point of time of the tenure of these posts is now more common, but that such a tenure could not be determinable by notice was the gist of Sir THOMAS BARLOW's evidence upon this head. Naturally he admitted that misconduct would justify dismissal; but this, he pointed out, should only take place after proper inquiry, and there should be a tribunal of arbitration for the settlement of disputes between opposing sections of the staff if there should be any disagreement to justify such intervention. The desirability of arbitration of an independent character does not appear to have occurred to the committee of the St. John's Hospital for Diseases of the Skin, the members of which failed to recognise that, owing to the position occupied by Dr. DOCKRELL and other matters, they were not the right persons to adjudicate upon what amounted to a dispute between themselves and the plaintiffs. In addition to this, one of their number, who took the chair at their meetings, appears to have increased rather than diminished the friction methods which the new regulations are framed to secure. The organisation has done a good service in putting the case before those immediately concerned in this practical way. It is often urged that the regulations drawn up by Government departments are seldom founded on practical considerations, a criticism which can only be met effectively by submitting the proposals to practical treatment, as has been done in the case of the health regulations in the pottery trade by the leading potters themselves. It must be a source of satisfaction to the Home Office authorities, and particularly to the Chief Inspector of Factories, Sir Arthur Whitelegge, to learn the view of practical authorities, that if the regulations are carried out thoroughly the potters' calling should soon become a healthy one. In order to assist all those who are willing to help to bring about the praiseworthy consummation indicated, Mr. Burton has compiled a careful analysis[1] of the regulations governing the manufacture of pottery in the British Isles. This pamphlet places in the hands of manufacturers, managers, foremen, and workpeople a digest setting forth in plain and simple terms the regulations devised for the better protection of the health of all pottery workers, together with such explanations, hints, and advice as are bound to be helpful.

HARD WATER FALLACIES.

WE have received a communication from a lay correspondent who expresses his belief "that the lime in common water has much to do with bringing on old age," and that therefore everyone should drink distilled water. We fancy this belief is fairly common, but of course it is fatuous. The supporters of this view seem to regard water as the only possible channel by which lime salts are conveyed to the organism. They appear to forget altogether the fact that lime salts are inseparable from the common everyday articles of food, so that if hard water were left out of the dietary there would still be secured a large intake of lime salts which could only be avoided by a hunger strike. A tumbler of hard water rarely contains 1 or at most 2 grains of chalk, and a baby requires, on theoretical considerations, at least 4 grains of lime daily. Assuming that the average daily amount of water consumed is about five tumblers, the amount of lime daily introduced into the economy through this vehicle would not exceed 10 grains, assuming the water to be very hard. But the amount introduced in food is much more than this. A pint of milk, for example, contains more lime salts than a pint of lime water, the amount in milk being about 10 grains. Eggs, the cereals, and vegetables contribute their quota, and when the total amount of such foods consumed per day is taken into the calculation the ingestion of lime salts is clearly considerable, apart altogether from what may be taken in solution by drinking even the hardest water. It is probable that the amount of lime salts taken through food easily exceeds the quantity present in gallons of hard water; the use of distilled water therefore provides an ineffective method for preventing the mischief which it is assumed lime salts may do the body. Also the drinking of distilled water is opposed to physiological considerations and may produce injury to the organism. When cells are placed in distilled water the passage of the water into the cells rapidly occurs owing to a difference of osmotic pressure, and the cells swell up and may finally burst and die. This action, which can correctly be described as poisonous, is observed when distilled water is drunk, for in this case the surface layers of the epithelium of the stomach undergo considerable swelling; salts also may pass out and the cells die and be cast off. Such a process may well resolve itself into a catarrh of the stomach. There is a continental water which is remarkably pure but poisonous because it produces gastritis for the reasons just quoted. It is doubtful whether hard waters are unwholesome, but the inconvenience caused by the furring of domestic services and kitchen apparatus by the deposit of chalk from such waters is very real, and affords a just cause of complaint in many London districts. There are no expenses connected with the storage or filtration of the deep-well supplies in the metropolitan area, as is the case with the river supplies. The deep-well waters are neither stored nor filtered, and therefore they might be softened. The water so treated, however, would not have the qualities of distilled water, nor would its use avoid "bringing on old age."

THE VALUE OF MOSQUITO KILLING IN HOUSES AS AN ANTIMALARIAL MEASURE.

MODERN antimalarial measures aim at the destruction of the insect host of the specific parasites and the prevention of the transference of the latter from one host to the other. The methods generally employed for the extermination of mosquitoes are directed chiefly towards the abolition of their breeding places and the destruction of their eggs and larvæ. It has been regarded by many persons as absolutely futile to attempt to extirpate the mature insect in infected localities, though it is admitted by others that some temporary benefit might, perhaps, follow the reduction of the number of mosquitoes in a given area. It cannot be denied that the abolition of mosquito breeding places often involves the construction of engineering or sanitary works which cause considerable expense. This question of expenditure has been put forward as one of the main arguments against the adoption of the modern scientific methods of malaria prophylaxis, and it is obvious that such outlay could hardly be justified in the case of small communities, and more particularly of temporary camps within malarious districts. Our attention has been directed recently to this subject by an interesting paper published in our contemporary the *American Journal of Public Health* (Vol. III., No. 2) by Dr. A. J. Orenstein, assistant chief sanitary inspector, Isthmian Canal Commission. In this paper the value of "mosquito catching" in dwellings as a prophylactic measure against malaria, more especially in temporary encampments, is emphasised, and a description is given of the methods which this expert employs to effect his purpose. The various means used for killing mosquitoes, anophelines and others, include an ordinary "slapper" made of a 6-inch square wire gauze attached to a 2-foot stick; a glass phial, such as is commonly employed by entomologists for collecting insects, containing a plug wetted with chloroform; and, lastly, a mosquito trap devised by a member of his staff. With this equipment the mosquito catcher passes from hut to hut. If the dwellings be screened the catching is done early in the morning and again in the evening. If the hut be not screened and the anophelines are abundant, search for them is made four or five times daily. As proof of the success of his methods Dr. Orenstein quotes the results obtained by him in four camps situated in the jungle along the line of construction of the new Panama railroad, where some 1200 labourers were housed in "screened cars." Anophelines were very numerous, and but little could be done in the way of attacking the mosquito breeding places by which the camps were surrounded. By killing systematically day by day the mosquitoes found within the huts in the manner above described it was found possible at a trivial cost to keep for a period of two or more years the malaria incidence-rate in the camps practically as low as that of the remainder of the canal zone methods which the new regulations are framed to secure. The organisation has done a good service in putting the case before those immediately concerned in this practical way. It is often urged that the regulations drawn up by Government departments are seldom founded on practical considerations, a criticism which can only be met effectively by submitting the proposals to practical treatment, as has been done in the case of the health regulations in the pottery trade by the leading potters themselves. It must be a source of satisfaction to the Home Office authorities, and particularly to the Chief Inspector of Factories, Sir Arthur Whitelegge, to learn the view of practical authorities, that if the regulations are carried out thoroughly the potters' calling should soon become a healthy one. THE VALUE OF MOSQUITO KILLING IN HOUSES AS AN ANTIMALARIAL MEASURE.

MODERN antimalarial measures aim at the destruction of the insect host of the specific parasites and the prevention of the transference of the latter from one host to the other. The methods generally employed for the extermination of mosquitoes are directed chiefly towards the abolition of their breeding places and the destruction of their eggs and larvæ. It has been regarded by many persons as absolutely futile to attempt to extirpate the mature insect in infected localities, though it is admitted by others that some temporary benefit might, perhaps, follow the reduction of the number of mosquitoes in a given area. It cannot be denied that the abolition of mosquito breeding places often involves the construction of engineering or sanitary works which cause considerable expense. This question of expenditure has been put forward as one of the main arguments against the adoption of the modern scientific methods of malaria prophylaxis, and it is obvious that such outlay could hardly be justified in the case of small communities, and more particularly of temporary camps within malarious districts. Our attention has been directed recently to this subject by an interesting paper published in our contemporary the *American Journal of Public Health* (Vol. III., No. 2) by Dr. A. J. Orenstein, assistant chief sanitary inspector, Isthmian Canal Commission. In this paper the value of "mosquito catching" in dwellings as a prophylactic measure against malaria, more especially in temporary encampments, is emphasised, and a description is given of the methods which this expert employs to effect his purpose. The various means used for killing mosquitoes, anophelines and others, include an ordinary "slapper" made of a 6-inch square wire gauze attached to a 2-foot stick; a glass phial, such as is commonly employed by entomologists for collecting insects, containing a plug wetted with chloroform; and, lastly, a mosquito trap devised by a member of his staff. With this equipment the mosquito catcher passes from hut to hut. If the dwellings be screened the catching is done early in the morning and again in the evening. If the hut be not screened and the anophelines are abundant, search for them is made four or five times daily. As proof of the success of his methods Dr. Orenstein quotes the results obtained by him in four camps situated in the jungle along the line of construction of the new Panama railroad, where some 1200 labourers were housed in "screened cars." Anophelines were very numerous, and but little could be done in the way of attacking the mosquito breeding places by which the camps were surrounded. By killing systematically day by day the mosquitoes found within the huts in the manner above described it was found possible at a trivial cost to keep for a period of two or more years the malaria incidence-rate in the camps practically as low as that of the remainder of the canal zone attack with cramp, nausea, pyrexia, and formation of a movable mass 2 inches in diameter, 2½ inches below and to the left of the umbilicus. The mass was tender for a few days and then it diminished. The bowels had a tendency to be loose. A few days later an operation was performed. A mass of about the size of half a lemon was found in the middle of the sigmoid flexure adherent to adjacent coils of bowel. There were some fresh adhesions from the recent attack and old and firm ones from previous attacks. The bowel was very œdematous and the fatty tissue about the diverticulum was much thickened and infiltrated. The mass was excised. In the diverticulum a mass of fæces of the size of a marble was found. The healing of the wound was delayed by a fæcal fistula. The early age—30 years—at which the diverticulum was found in this case is noteworthy. In some cases malignant changes take place. Thus a man, aged about 65 years, gave a history of good health until the last year, in which he had suffered from indefinite attacks of pain on the left side of the abdomen. When he was seen there had been complete obstruction of the bowels for two days. Nothing had been passed in spite of the administration of cathartics and enemata. On operation cancer of the sigmoid, presumed to be secondary to diverticulitis, was found. Primary resection was performed according to the method of Dr. W. J. Mayo, a large rubber tube being used to complete the anastomosis. While the patient was convalescing a fatal attack of pneumonia occurred.

RADIUM SPRINGS IN BRITISH COLUMBIA.

IN THE LANCET of March 11th, 1911, we published an analysis from our laboratory of samples of water taken from three springs situated in the Sinclair Pass in British Columbia. These springs are grouped on the east bank of the Columbia river, about 60 miles south of Golden and 13 miles north of Windermere. They are not far (some 50 miles) from the well-known sulphur waters at Banff, and altogether the district seems well served with mineral waters, but those in the Sinclair Pass would appear to be unique, inasmuch as recent investigation has shown that they are powerfully radio-active. The temperature of the waters is 115° F., so that they are correctly described as thermal. In considering the results of our analysis we pointed out the probability of the waters showing, when examined at the source, marked radio-active properties. Curiously enough, the mineral ingredients proved to be similar in kind and amount to those found in the Bath waters, which are also thermal and radio-active. The important observation has been made now that, apart from the emanations, the Sinclair water must contain, according to well-known methods of deduction, radium itself. Subsequent examination made at the laboratories of the McGill University, Montreal, showed that the Sinclair springs contain more radium and radium emanation than are present in the Bath waters. There should be a future for the application of these waters in therapeutics, since they show a radio-activity which is not equalled, as far as inquiry has gone, elsewhere. For a long time the waters have had a considerable local reputation in the treatment of gout, rheumatism, and skin diseases, and practice has furnished evidence that they are effective in ministering to those diseases which are known to be benefited by a course of radio-active treatment. It is believed that rich radium-bearing earths occur in the neighbourhood, a belief which we hope is well founded, since the world's supply so far is all too short for wide and effective medical treatment. We learn that deposits of pitchblende (uranium ore) have been found, and the belief is that these will show a valuable return of radium. Any augmentation of the supply of radium will be welcomed, for without this increased supply the science of radiotherapeutics must necessarily advance slowly.

SPIROCHÆTA PALLIDA IN GENERAL PARALYTICS.

IN a paper read before the St. Louis Medical Society and published in their *Weekly Bulletin* of June 5th, Dr. William W. Graves narrates the results of his experiences in attempts to cultivate or otherwise demonstrate the presence of the spirochæta pallida in the blood and spinal fluid of syphilitics. Search by means of dark-field illumination, Indian ink, or other ordinary methods only showed the presence of spirochætæ in three cases out of 500 specimens, two cases in which the blood was positive being florid syphilitics, and one in which the cerebro-spinal fluid revealed the presence of the organism being a case of lues spinalis. Cultivation on Noguchi's medium proved positive in two cases out of 130, the infection dating in one case from a period 30 years and in the other 23 years previously. The most interesting results were, however, obtained by inoculation of rabbits' testicles with blood from cases of general paralysis and tabes dorsalis. Two positive results were obtained, one in a patient who had contracted infection 18 years before, and the other in a man infected 14 years previously, both of whom showed definite symptoms of general paralysis. Distinct areas of induration developed in the animals, and typical spirochætæ were found in them, while one rabbit manifested in addition lesions of the eyelids and perineum in which also the organisms were recognisable. Dr. Graves has no doubt that the spirochætæ found were true pallidæ, as he had had the opportunity of studying some of Noguchi's cultures as well as ordinary syphilitic material. He believes that the organisms remain alive in syphilitic subjects for an indefinite time, and that symptoms may therefore flare up long after infection. Tabes and general paralysis would seem, if these observations are confirmed, to be true syphilitic lesions rather than parasyphilitic affections the result of past toxæmia. Until, however, these experiments have been repeated by other observers it will be well to suspend judgment as to these findings.

LITHIUM POISONING.

CASES of lithium poisoning are very rare. In the *Journal of the American Medical Association* of March 8th Mr. S. A. Cleaveland has described toxic symptoms which differ in some respects from those hitherto described. During an investigation on uric acid under Professor Haskins he took rather large doses of lithium chloride. In a first experiment he took 2 grm. in a glass of water three times in the day after meals and a dose on the following day, making a total of 8 grm. in 28 hours. Three or four hours after the first dose he suffered from slight dizziness and fulness in the head. After the second dose he noticed nothing. Soon after the third dose vision was much blurred and nothing smaller than the largest headlines of a newspaper could be read. There were marked dizziness and tinnitus. The fourth dose was taken at night and the dizziness was such that the room seemed to go round all night and sleep was almost impossible. Next morning he was much prostrated. The ocular symptoms were increased and dizziness, weakness, and tremors were so intense that he had to go to bed. The ocular and aural symptoms lasted about 36 hours after the last dose and weakness and tremors for five days. At no time were there gastro-intestinal symptoms and the appetite remained good. Several months later the experiment was repeated to make certain that the effects were due to lithium. Only two doses of 2 grm. each were necessary to bring on the dizziness, attack with cramp, nausea, pyrexia, and formation of a movable mass 2 inches in diameter, 2½ inches below and to the left of the umbilicus. The mass was tender for a few days and then it diminished. The bowels had a tendency to be loose. A few days later an operation was performed. A mass of about the size of half a lemon was found in the middle of the sigmoid flexure adherent to adjacent coils of bowel. There were some fresh adhesions from the recent attack and old and firm ones from previous attacks. The bowel was very œdematous and the fatty tissue about the diverticulum was much thickened and infiltrated. The mass was excised. In the diverticulum a mass of fæces of the size of a marble was found. The healing of the wound was delayed by a fæcal fistula. The early age—30 years—at which the diverticulum was found in this case is noteworthy. In some cases malignant changes take place. Thus a man, aged about 65 years, gave a history of good health until the last year, in which he had suffered from indefinite attacks of pain on the left side of the abdomen. When he was seen there had been complete obstruction of the bowels for two days. Nothing had been passed in spite of the administration of cathartics and enemata. On operation cancer of the sigmoid, presumed to be secondary to diverticulitis, was found. Primary resection was performed according to the method of Dr. W. J. Mayo, a large rubber tube being used to complete the anastomosis. While the patient was convalescing a fatal attack of pneumonia occurred.

RADIUM SPRINGS IN BRITISH COLUMBIA.

IN THE LANCET of March 11th, 1911, we published an analysis from our laboratory of samples of water taken from three springs situated in the Sinclair Pass in British Columbia. These springs are grouped on the east bank of the Columbia river, about 60 miles south of Golden and 13 miles north of Windermere. They are not far (some 50 miles) from the well-known sulphur waters at Banff, and altogether the district seems well served with mineral waters, but those in the Sinclair Pass would appear to be unique, inasmuch as recent investigation has shown that they are powerfully radio-active. The temperature of the waters is 115° F., so that they are correctly described as thermal. In considering the results of our analysis we pointed out the probability of the waters showing, when examined at the source, marked radio-active properties. Curiously enough, the mineral ingredients proved to be similar in kind and amount to those found in the Bath waters, which are also thermal and radio-active. The important observation has been made now that, apart from the emanations, the Sinclair water must contain, according to well-known methods of deduction, radium itself. Subsequent examination made at the laboratories of the McGill University, Montreal, showed that the Sinclair springs contain more radium and radium emanation than are present in the Bath waters. There should be a future for the application of these waters in therapeutics, since they show a radio-activity which is not equalled, as far as inquiry has gone, elsewhere. For a long time the waters have had a considerable local reputation in the treatment of gout, rheumatism, and skin diseases, and practice has furnished evidence that they are effective in ministering to those diseases which are known to be benefited by a course of radio-active treatment. It is believed that rich radium-bearing earths occur in the neighbourhood, a belief which we hope is well founded, since the world's supply so far is all too short for wide and effective medical treatment. We learn that deposits of pitchblende (uranium ore) have been found, and the belief is that these will show a valuable return of radium. Any augmentation of the supply of radium will be welcomed, for without this increased supply the science of radiotherapeutics must necessarily advance slowly.

SPIROCHÆTA PALLIDA IN GENERAL PARALYTICS.

IN a paper read before the St. Louis Medical Society and published in their *Weekly Bulletin* of June 5th, Dr. William W. Graves narrates the results of his experiences in attempts to cultivate or otherwise demonstrate the presence of the spirochæta pallida in the blood and spinal fluid of syphilitics. Search by means of dark-field illumination, Indian ink, or other ordinary methods only showed the presence of spirochætæ in three cases out of 500 specimens, two cases in which the blood was positive being florid syphilitics, and one in which the cerebro-spinal fluid revealed the presence of the organism being a case of lues spinalis. Cultivation on Noguchi's medium proved positive in two cases out of 130, the infection dating in one case from a period 30 years and in the other 23 years previously. The most interesting results were, however, obtained by inoculation of rabbits' testicles with blood from cases of general paralysis and tabes dorsalis. Two positive results were obtained, one in a patient who had contracted infection 18 years before, and the other in a man infected 14 years previously, both of whom showed definite symptoms of general paralysis. Distinct areas of induration developed in the animals, and typical spirochætæ were found in them, while one rabbit manifested in addition lesions of the eyelids and perineum in which also the organisms were recognisable. Dr. Graves has no doubt that the spirochætæ found were true pallidæ, as he had had the opportunity of studying some of Noguchi's cultures as well as ordinary syphilitic material. He believes that the organisms remain alive in syphilitic subjects for an indefinite time, and that symptoms may therefore flare up long after infection. Tabes and general paralysis would seem, if these observations are confirmed, to be true syphilitic lesions rather than parasyphilitic affections the result of past toxæmia. Until, however, these experiments have been repeated by other observers it will be well to suspend judgment as to these findings.

LITHIUM POISONING.

CASES of lithium poisoning are very rare. In the *Journal of the American Medical Association* of March 8th Mr. S. A. Cleaveland has described toxic symptoms which differ in some respects from those hitherto described. During an investigation on uric acid under Professor Haskins he took rather large doses of lithium chloride. In a first experiment he took 2 grm. in a glass of water three times in the day after meals and a dose on the following day, making a total of 8 grm. in 28 hours. Three or four hours after the first dose he suffered from slight dizziness and fulness in the head. After the second dose he noticed nothing. Soon after the third dose vision was much blurred and nothing smaller than the largest headlines of a newspaper could be read. There were marked dizziness and tinnitus. The fourth dose was taken at night and the dizziness was such that the room seemed to go round all night and sleep was almost impossible. Next morning he was much prostrated. The ocular symptoms were increased and dizziness, weakness, and tremors were so intense that he had to go to bed. The ocular and aural symptoms lasted about 36 hours after the last dose and weakness and tremors for five days. At no time were there gastro-intestinal symptoms and the appetite remained good. Several months later the experiment was repeated to make certain that the effects were due to lithium. Only two doses of 2 grm. each were necessary to bring on the dizziness, below with that of the internal iliac artery, and its cavity was connected with the lumen of the common iliac artery, the external iliac artery springing from its lower end. This cavity was nearly full of reddish-grey clot which appeared to be caseous. The channel by which it communicated with the arterial lumen was small and appeared to have been formed by a limited rupture of the intima and media, the outer wall of the aneurysmal sac consisting of adventitia only. This communication was partially occluded by a polypoid mass of clot springing from the intima of the common iliac artery; this clot, as well as that lying within the sac, contained large numbers of acid-fast bacilli. Tuberculous lesions were also found in the lungs, kidneys, spleen, liver, intestines, bladder, prostate, and right seminal vesicle. In Professor Haythorn's judgment, the appearance of lesions indicated an infection of the arterial wall from without inwards; but whether from a focus in the vertebral column or the neighbouring lymph nodes he was unable to determine. This interpretation of the case brings it into line with the other examples of tuberculous aneurysm of systemic arteries which he was able to collect from the literature.

Dr. W. P. Herringham has been re-elected Vice-Chancellor of the University of London.

A PLEA FOR THE APPOINTMENT OF A ROYAL COMMISSION ON VENEREAL DISEASE.

BY SIR MALCOLM MORRIS, K.C.V.O.

To insist in a medical journal that venereal diseases cannot be successfully combated so long as the State holds aloof from the conflict, and that the time has come for an investigation by a Royal Commission of the whole question of their prevalence and incidence and the best means of controlling them, is almost a work of superfluity. At first sight it seems strange enough that while the State compels local authorities to build asylums for the insane, encourages them to make provision for the segregation of cases of infectious fevers, enforces the notification of many infectious diseases, and laboriously builds up a vast system of public health legislation, it chooses to stand aside [illegible] contagious and so dire in its [illegible] baleful course unchecked by t[illegible] control. The anomaly can only be explained by reference to the reticence on sexual subjects which since the Puritan era has been a characteristic of the British mind. I have no intention of denouncing that mental habit At its best it is no offspring of the hypocrisy to which many critics have pleasantly attributed it. But none the less it is a disastrously mistaken counsel, the effect of which is to allow a free course in the body politic to gross evils which might be substantially checked were they but frankly recognised and boldly grappled with. Fortunately there are indications that the policy of silence is breaking down. The blast of public indignation which assisted the passage of the Bill to suppress what is popularly known as the white slave traffic, and the recognition of syphilis as a racial poison in works on social reform intended for general reading, are evidences that the more enlightened of the laity are coming to see that it is better to bring the force of public opinion to bear upon evil things than to ignore their existence. Surely it is not too much to hope that the Government will strengthen this essentially wholesome tendency by ordering a thorough exploration of the whole subject of venereal disease.

In these paragraphs I shall deal chiefly with syphilis partly because it is the venereal disease with which my work as a dermatologist has given me intimate familiarity, but also because, widespread as is gonorrhœa, and serious as are its consequences, especially in women, if left untreated, syphilis none the less forms much the more important branch of the subject. If the effects of this disease were confined to those who acquire it and those whom they directly infect with it, the State would still lie under an imperative obligation to do what it can to hinder its spread and mitigate its effects. But the case for legislative action becomes incomparably stronger in view of the fact that syphilis is one of the rare conditions that can be transmitted from parent to child, so that the offspring of a syphilitic may be born not with a mere predisposition to the disease, as in tuberculosis, but with the virus actually in its tissues, to cause, it may be, hideous deformity, or blindness, or deafness, or epilepsy, or idiocy, ending often in premature though not untimely death. Even that is an understatement of the case, for syphilis is a prolific cause of death before birth. In these days of a falling birth-rate and of an international rivalry in which the weight of numbers is one of the factors of national success or failure, a disease which is so frequent a cause of abortion, which at the best diminishes efficiency and at the worst consigns its victims to our asylums and infirmaries and workhouses and prisons, or to an early grave, cannot continue to be a matter of indifference to the State.

Syphilis of the Innocent.

The old view that syphilis is a divinely ordained penalty for illicit sexual indulgence, and that it is wrong, therefore, to seek to avert it, now seldom finds formal expression. Unconsciously, no doubt, it still colours the thought and feeling of many. But as a dogma it has gone the way of the argument which Simpson had to meet when he began to use chloroform to allay the pangs of difficult labour—that it was sinful to mitigate the penalty attached to childbearing as the result of [illegible] Eden. Even now, how [illegible] the extent to which [illegible]. Did they but know how large a proportion of those who contract these diseases are the innocent victims of cruel misfortune their attitude towards this subject would be sensibly affected. The babes who are infected before birth with syphilis or at birth with gonorrhœa which may cause irremediable blindness, the wives to whom these diseases are conveyed by their husbands, the children to whom the father's kiss communicates syphilis, the industrial workers who acquire it from the use of infected implements, the wet nurses who are contaminated by the children whom they nourish, the medical men and nurses and midwives who are inoculated with it in handling patients who may not be known to be syphilitic—these make up an immense multitude of those who are entirely innocent of moral wrong. A striking example of syphilis insontium was recently recorded by Dr. J. F. Schamberg, of Philadelphia[1]. Following a benefit performance, a company of youths and girls, whose ages ranged from 16 to 22, engaged in kissing games. One of the youths had a sore on the lip, and in due course six girls whom he kissed developed labial chancres, as also did a seventh girl whom he kissed at another party, while a young man was apparently infected by kissing one of the girls while the contagion was fresh upon her lip. Besides its immediate moral, the dangers of promiscuous kissing, the incident suggests more generally the perils of an ignorance of which the last thing that could be predicated is that it is "wise." It is more than time such ignorance were ended, and the State should no longer be a party to the conspiracy of silence which yields fruits such as these.

Is Syphilis Increasing?

If this question be asked, the failure of the State to do its duty is at once brought into relief. The result of its policy of non interference is that no statistics are available which [illegible] I do not pro- [illegible] bear upon the [illegible] but when one remembers the ease with which syphilis is communicated, and the absence of any systematised effort to treat it and check its spread, the antecedent probabilities are against any such diminution in this disease as has been effected, mainly as the result of public health legislation, in many others. That syphilis has an extremely wide distribution every medical man knows. In the illuminating discussion on Syphilis by the Royal Society of Medicine last year[2] it was calculated by Dr. Douglas White that in London there are 40,000 fresh cases of syphilis every year, and in the United Kingdom as a whole 130,000 cases. This is but an estimate, but my own observation during a long professional career inclines me to believe that it is at least as likely to be an under- as an over-calculation.

below with that of the internal iliac artery, and its cavity was connected with the lumen of the common iliac artery, the external iliac artery springing from its lower end. In the illuminating discussion on Syphilis by the Royal Society of Medicine last year[2] it was calculated by Dr. Douglas White that in London there are 40,000 fresh cases of syphilis every year, and in the United Kingdom as a whole 130,000 cases. This is but an estimate, but my own observation during a long professional career inclines me to believe that it is at least as likely to be an under- as an over-calculation.

MEDICINE AND THE LAW.

Liability for Infection with Puerperal Fever.

IN the case of Heathcote *v.* Chadwick and others, recently tried by Mr. Justice Pickford and a special jury, the plaintiff was a widower who claimed compensation for the loss of his wife by puerperal fever from the authorities of an institution which had provided a nurse to attend her in her confinement. The nurse did not give the whole of her time to the plaintiff's wife, but attended also another woman who undoubtedly contracted puerperal fever. Upon this being diagnosed the nurse ceased to attend the deceased, but it was too late to prevent her from being infected. The plaintiff alleged negligence on the part of the defendants in allowing the nurse to attend both women, and also that the nurse was negligent, as she ought to have known even before the case of the second one was diagnosed as puerperal fever that it was dangerous for her to attend both women, and further that the matron who sent her out was negligent in letting her continue attending the deceased when she, the matron, knew that a rise of temperature had taken place in the other patient. Mr. Justice Pickford, in summing up, told the jury that they had to decide from the evidence whether the defendants agreed "to nurse the plaintiff's wife" or only "to supply a nurse to attend her." In the former case the defendants would be liable for any negligence of the nurse. In the latter case they would not be responsible for any negligence of the nurse, but they might be liable for negligence if the matron allowed the nurse to attend the plaintiff's wife when she should not have allowed her to do so. The jury found that the contract was to provide a nurse, but failed to agree as to whether there was any negligence on the part of the nurse or of the matron.

Unqualified Dentists and Cocaine: A Jury's Recommendation.

A case in which a married woman died a few minutes after an injection of cocaine, given to her by an unqualified dentist, was before Mr. H. C. Yates, the coroner for Cheshire, on June 6th. The unqualified dentist, Ernest Edwards, of Nantwich, admitted having injected a quantity of cocaine into the woman's gums. He said he had 32 years' experience of dental work, but had never had such a case before. In summing up the coroner said he had searched but could not find any statute prohibiting any person who was not a qualified medical man or dental practitioner from administering anæsthetics or any other drug. But if an unqualified person who administered it led the public to believe that he was a qualified man he was liable to a penalty. He thought that in view of the fact that there was so much of this injecting going on by unqualified persons, the sooner something was done to prevent it the better it would be for the public. If the jury thought that Edwards was guilty of gross or culpable negligence in the way he performed the operation it would be their duty to put him upon trial for manslaughter, but it must be proved that the anæsthetic was the direct cause of death, and that it was not due to any contributory cause. He was bound to say in this case, although he did so with considerable reluctance, that he did not think there was sufficient evidence to place Edwards on his trial. The jury returned a verdict that death was due to misadventure, but added a recommendation that the law should be so amended as to prohibit the use of anæsthetics except by fully qualified practitioners. The coroner said he cordially agreed with the recommendation and would communicate it to the Home Office.

An Interesting Case for Compensation.

During the hearing of a compensation case at the Salford county court on June 9th Judge Mellor had before him a case for approval of a settlement of a compensation claim made by H. Clarke, aged 21, for loss of the sight of his left eye, caused through the bursting of a bottle in September last. It was stated that the medical opinion was to the effect that the young man could now return to work, and that he had agreed to accept £80 and costs in commutation of any liabilities that might arise in the future. The judge remarked that the "workman" in this case was practically only a boy. For such an accident as this he certainly should not allow him to settle for less than £80, in addition to the cost of having an artificial eye put in. Continuing, the judge said, "I have now been here sufficiently long to have a tabulated idea as to the value of every limb and every part of a man's frame." Before he consented to settlement he should at least insist on being assured by medical evidence that future removal of the injured eye could not affect the remaining one. The case was adjourned for medical evidence to be called.

RESEARCH DEFENCE SOCIETY.

THE annual meeting of the Research Defence Society was held at the Royal College of Physicians of London on June 24th, when Sir **DAVID GILL** presided.

The Right Rev. Bishop **FRODSHAM** said that the society had fully justified its existence, and had done a great deal to create a healthy public opinion with regard to a subject which had been much misrepresented. Scientific research was shown not to be contrary to the principles of Christianity.

Mr. **SYDNEY HOLLAND**, in moving the adoption of the report of the committee, which stated that the society was steadily gaining recognition and exercising more influence over public opinion, having during the year recruited more than 400 members and associates, referred to the decision of the committee to open a number of shops to counteract the influence of the Antivivisection Society, and remarked that that was one of the best possible ways of promoting the cause of true science and true humanity. Referring to the Bills for the protection of dogs which were at present before Parliament, one of which had already passed a second reading, he showed that the animals themselves had benefited by research, instancing, among other things, inoculation for distemper.

The motion was seconded by Sir **HUGH BELL** and adopted.

The Treasurer's report, which was submitted by Dr. F. M. **SANDWITH**, stated that last year the subscriptions received by the parent society showed an excess of £113, while the contributions from branches were also £100 in excess of the previous year. On the present occasion, the report pointed out, the subscriptions to the parent society show a diminution of £106, while the contributions from the branches only slightly exceed the amount paid during 1911. This is presumably not due to any loss of interest in the society, but rather to the fact that many supporters consider it unnecessary to continue their subscriptions after the issue of the report of the Royal Commission on Vivisection.

Sir **DAVID GILL** in his presidential address, after referring to the need for the existence of the Research Defence Society in protecting science from the disastrous effects which would follow the kind of legislation which certain people were advocating, said that in order to combat the misleading statements of their opponents it was proposed to open a shop in London where the truth about the Research Society could be put before the public day by day, and for this purpose £600 were required, of which £340 had already been received. He urged the public before joining any of the antivivisection societies to read the final portion of the report of the Royal Commission which was published last year.

Lord **CROMER**, referring to the non-election of Lord Cheylesmore to the council of the Royal Society for the Prevention of Cruelty to Animals, said he had instituted a protest as he believed the result was due to a snap vote. If Lord Cheylesmore was not replaced on the council of the Royal Society for the Prevention of Cruelty to Animals he himself would withdraw from the society and he hoped others would do the same.

Sir **THOMAS BARLOW**, President of the Royal College of Physicians of London, explained that the College was grateful to the Research Defence Society for the work which it had done in defending men who could not well defend themselves from serious misrepresentation. All who were engaged in the practice of medicine and surgery who were not themselves able to carry on the experiments necessary for the advance of science and the amelioration of human suffering acknowledged the courage, energy, and spirit of the society.

A vote of thanks to the President was proposed by Mr.
the vote Sir **DAVID**

Correspondence.

"Audi alteram partem."

THE WELSH NATIONAL MEMORIAL AND THE POSITION OF THE COUNTY COUNCILS.

To the Editor of THE LANCET.

SIR,—Mr. Gwilym Hughes must be of an optimistic temperament if he honestly is satisfied with the general feeling with regard to the National Memorial scheme.

It [illegible] scheme is distasteful to the [illegible] officers of health and to [illegible]ners, and without the sympathy of these men success cannot result. The Pembrokeshire county council are forwarding to the Commissioners their own scheme for approval, which is, in their opinion, less elaborate, less extravagant, and more efficacious, and which leaves the control of public health where it ought to be—in the hands of the county sanitary authority and their medical officer of health.

A scheme that has an income from invested capital of £6000 a year and which pays £8000 a year in salaries is hardly likely to have a prosperous career unless it is heavily supported by the rates.

I am, Sir, yours faithfully,

A. HURRELL STYLE, M.D. Cantab.,
Member, Pembrokeshire County Council.

Pembroke, June 23rd, 1913.

⁂ Mr. Hughes was too engaged in contradicting our paragraph to notice that he was contradicting himself.—ED. L.

WHEN TO DIAGNOSE APPENDICITIS.

To the Editor of THE LANCET.

SIR,—Whilst eminent surgeons have been discussing in your columns the important question of "When to operate in appendicitis," many a practitioner must have been perplexed on the question of early diagnosis of the same disease in actual practice. If he is to follow out the most up-to-date teachings he must be prepared to take the responsibility of either calling in a surgeon or sending the patient to hospital.

There must be a perfect understanding between the practitioners and the hospitals so that any case sent to hospital on the written recommendation of a medical man should receive due and tactful consideration, otherwise the desirable rule of getting patients early into the hands of a surgeon will not be observed. To make my meaning clearer the following account of an incident which happened recently will suffice.

I was asked to see a young woman who complained of intense agony over the region of the appendix on examination. She had been seen some ten hours previously by a colleague, who diagnosed appendicitis and treated her accordingly. In the interval her symptoms had increased. I agreed with the diagnosis and considered the case one fit for operation. I wrote on a visiting card my diagnosis and recommendation and sent her to a London hospital. The next day I was sent for and informed that she had been examined at the hospital, given some medicine, and sent home and told to come back in the morning. I again examined her and found that her symptoms had further increased, and in addition she had retention of urine, due no doubt to drugs. I emptied the bladder with a catheter, but this did not cause the acute pain over the appendix to diminish. She was sent to another London hospital, where she was operated upon at once.

There is no suggestion of any neglect in this short account of what happened, as I am aware of the large number of trivial cases which go or are sent to our large hospitals. I do suggest that when a medical man gives his written diagnosis of appendicitis to a patient the hospital authorities should take into consideration the position of the medical attendant, who, amongst other things, is losing a patient by his procedure.

To give a definite written diagnosis of appendicitis and to take the responsibility of sending to hospital, and then to have the patient sent home without being admitted, is not going to increase one's desire to make attempts at early diagnosis of appendicitis, and it certainly cannot improve one's reputation locally. When the same case is operated upon next day in another London hospital one is inclined to doubt whether all that has been written in the columns of THE LANCET on the question of appendicitis and its operation has been fully appreciated both inside and outside the walls of our large hospitals.

I am, Sir, yours faithfully,

Castle-court, Cornhill, E.C., June 23rd, 1913. J. J. SCANLAN.

A NEW SPIROCHÆTA FOUND IN HUMAN BLOOD.

To the Editor of THE LANCET.

SIR,—*My attention has been directed to a paper by Dr.* Helen Chambers in THE LANCET for June 21st entitled "A New Spirochæta found in Human Blood," and recording the discovery of a spirochæte in the blood in Graves's disease and also in the blood of a certain number of healthy persons. I fear there can be little doubt that Dr. Chambers has fallen into error, and has mistaken the results of certain curious changes which occur in red cells for spirochætæ. Certainly, Fig. 1 of her article, which is supposed to represent the spirochætæ as seen by dark ground illumination, is merely a very excellent picture of these alterations which were first described by Nuttall and Graham Smith, and with which I have dealt fully in my paper on Fallacies and Puzzles in Blood Examination in Vol. A of the Fourth Report of the Wellcome Tropical Research Laboratories at Khartoum (1911).

I am, Sir, yours faithfully,

June 24th, 1913. ANDREW BALFOUR.

To the Editor of THE LANCET.

SIR,—I read with interest the preliminary communication concerning "A New Spirochæta found in Human Blood" by Dr. Helen Chambers in your issue of June 21st. I suppose that most bacteriologists who are in the habit of examining blood cultures have met with the bodies described in this communication.

Some four years ago I was cautioned by Dr. Charles Slater, then bacteriologist to St. George's Hospital, against mistaking for streptococcal chains bodies having a somewhat similar appearance that are met with in fresh preparations made from broth flasks inoculated previously with human blood. Since then, often having to examine bloods for the presence of organisms, I have constantly come across these bodies, to which I have given the name "filiform bodies." Looking through the notes that I have made since 1910 in connexion with these bodies I feel sure that the "spirochætæ" seen by Dr. Helen Chambers and the "filiform bodies" noticed by me are identical. It was suggested to me in February, 1912, by some one to whom I was demonstrating these filiform bodies under the microscope with dark-ground illumination, that they were little threads of fibrin.

If you could afford me space I should like here to mention a few facts in connexion with these bodies in the hope that some light may be thrown on their true nature.

1. If a little blood be taken from a finger under aseptic conditions, mixed with an equal volume of 2 per cent. sodium citrate in a sterile tube, and this plugged with sterile wool and placed at 37° C. for 24 hours and then examined by dark ground illumination, these filiform bodies may be seen. In this case the blood has not clotted—at least in the ordinary sense of the word.

2. If a clean sterile cover glass be taken and a small drop of blood from the finger obtained aseptically be placed on this and the cover then inverted and dropped on to a clean sterile slide and this cover glass preparation of fresh blood be then ringed round with vaseline the specimen may be kept for 24 hours or so and frequently observed. If this method is used the following phenomena may be noticed: (*a*) when the specimen is at once examined by dark ground illumination and a part chosen for examination where the red cells lie separate (1) [illegible] number of dancing b[illegible] few or many, (3) no [illegible] filaments are to be seen lying in the spaces between the red cells. Such a state of affairs may exist for an hour, and

"Audi alteram partem"

THE WELSH NATIONAL MEMORIAL AND THE POSITION OF THE COUNTY COUNCILS.

To the Editor of The Lancet

Sir,—Mr Gwilym Hughes must be of an optimistic temperament if he honestly is satisfied with the general feeling with regard to the National Memorial scheme

It [illegible] scheme is distasteful to the [illegible] officers of health and to [illegible]ners, and without the sympathy of these men success cannot result The Pembrokeshire county council are forwarding to the Commissioners their own scheme for approval, which is, in their opinion less elaborate, less extravagant and more efficacious, and which leaves the control of public health where it ought to be—in the hands of the county sanitary authority and their medical officer of health

A scheme that has an income from invested capital of £6000 a year and which pays £8000 a year in salaries is hardly likely to have a prosperous career unless it is heavily supported by the rates

I am, Sir yours faithfully,
A Hurrell Style M D Cantab,
Member, Pembrokeshire County Council

Pembroke, June 23rd 1913

WHEN TO DIAGNOSE APPENDICITIS.

To the Editor of The Lancet

Sir,—Whilst eminent surgeons have been discussing in your columns the important question of "When to operate in appendicitis," many a practitioner must have been perplexed on the question of early diagnosis of the same disease in actual practice If he is to follow out the most up-to-date teachings he must be prepared to take the responsibility of either calling in a surgeon or sending the patient to hospital

There must be a perfect understanding between the practitioners and the hospitals so that any case sent to hospital on the written recommendation of a medical man should receive due and tactful consideration otherwise the desirable rule of getting patients early into the hands of a surgeon will not be observed To make my meaning clearer the following account of an incident which happened recently will suffice

I was asked to see a young woman who complained of intense agony over the region of the appendix on examination She had been seen some ten hours previously by a colleague, who diagnosed appendicitis and treated her accordingly In the interval her symptoms had increased, I agreed with the diagnosis and considered the case one fit for operation I wrote on a visiting card my diagnosis and recommendation and sent her to a London hospital The next day I was sent for and informed that she had been examined at the hospital, given some medicine and sent home and told to come back in the morning I again examined her and found that her symptoms had further increased and in addition she had retention of urine, due no doubt to drugs I emptied the bladder with a catheter but this did not cause the acute pain over the appendix to diminish She was sent to another London hospital, where she was operated upon at once

There is no suggestion of any neglect in this short account of what happened, as I am aware of the large number of trivial cases which go or are sent to our large hospitals I do suggest that when a medical man gives his written diagnosis of appendicitis to a patient the hospital authorities should take into consideration the position of the medical attendant who, amongst other things, is losing a patient by his procedure

To give a definite written diagnosis of appendicitis and to take the responsibility of sending to hospital, and then to have the patient sent home without being admitted, is not going to increase one s desire to make attempts at early diagnosis of appendicitis, and it certainly cannot improve one s reputation locally When the same case is operated upon next day in another London hospital one is inclined to doubt whether all that has been written in the columns of The Lancet on the question of appendicitis and its operation has been fully appreciated both inside and outside the walls of our large hospitals

A NEW SPIROCHÆTA FOUND IN HUMAN *BLOOD*

To the Editor of The Lancet

Sir,—My attention has been directed to a paper by Dr. Helen Chambers in The Lancet for June 21st entitled "A New Spirochæta found in Human Blood," and recording the discovery of a spirochæte in the blood in Graves s disease and also in the blood of a certain number of healthy persons I fear there can be little doubt that Dr Chambers has fallen into error, and has mistaken the results of certain curious changes which occur in red cells for spirochætæ Certainly, Fig 1 of her article, which is supposed to represent the spirochætæ as seen by dark ground illumination, is merely a very excellent picture of these alterations which were first described by Nuttall and Graham Smith and with which I have dealt fully in my paper on Fallacies and Puzzles in Blood Examination in Vol A of the Fourth Report of the Wellcome Tropical Research Laboratories at Khartoum (1911)

I am, Sir, yours faithfully,
June 24th, 1913 Andrew Balfour

To the Editor of The Lancet

Sir,—I read with interest the preliminary communication concerning "A New Spirocheta found in Human Blood" by Dr Helen Chambers in your issue of June 21st I suppose that most bacteriologists who are in the habit of examining blood cultures have met with the bodies described in this communication

Some four years ago I was cautioned by Dr Charles Slater, then bacteriologist to St George's Hospital, against mistaking for streptococcal chains bodies having a somewhat similar appearance that are met with in fresh preparations made from broth flasks inoculated previously with human blood Since then often having to examine bloods for the presence of organisms I have constantly come across these bodies, to which I have given the name filiform bodies" Looking through the notes that I have made since 1910 in connexion with these bodies I feel sure that the "spirochetæ" seen by Dr Helen Chambers and the filiform bodies' noticed by me are identical It was suggested to me in February, 1912 by some one to whom I was demonstrating these filiform bodies under the microscope with dark-ground illumination that they were little threads of fibrin

If you could afford me space I should like here to mention a few facts in connexion with these bodies in the hope that some light may be thrown on their true nature

1 If a little blood be taken from a finger under aseptic conditions, mixed with an equal volume of 2 per cent sodium citrate in a sterile tube, and this plugged with sterile wool and placed at 37° C for 24 hours and then examined by dark ground illumination these filiform bodies may be seen In this case the blood has not clotted—at least in the ordinary sense of the word

2 If a clean sterile cover glass be taken and a small drop of blood from the finger obtained aseptically be placed on this and the cover then inverted and dropped on to a clean sterile slide and this cover glass preparation of fresh blood be then ringed round with vaseline the specimen may be kept for 24 hours or so and frequently observed If this method is used the following phenomena may be noticed (*a*) when the specimen is at once examined by dark ground illumination and a part chosen for examination where the red cells lie separate (1) [illegible] number of dancing b[illegible] few or many, (3) no [illegible] filaments are to be seen lying in the spaces between the red cells Such a state of affairs may exist for an hour, and

St. George's Hospital exceeds, I believe, £5000, whereas the sum which has caused the discussion with the King's Fund is very much smaller. It must be to the advantage, therefore, of St. George's Hospital to fall into line with all the other medical schools throughout London, and to end this controversy by adopting the resolution submitted on behalf of the house committee by Mr. Keyser.

It is notable that although a very full attendance of governors was reported only 29 voted, a majority of whom were, I believe, members of the medical staff.

I am, Sir, yours faithfully,

Porchester-square, W., June 23rd, 1913. HENRY C. BURDETT.

THE INGESTION OF BACTERIA BY THE SUBEPITHELIAL LYMPHATIC GLANDS IN HEALTH.

To the Editor of THE LANCET.

SIR,—My attention has been attracted by the interesting article by Dr. Kenelm H. Digby which appeared under the above title in THE LANCET of June 21st, p. 1731.

When in 1907 I first made a contribution on this subject[1] to THE LANCET I also was unaware of any previous work having been done on it. I find that on that occasion, as well as in a brochure published by me in the same year,[2] I advanced the hypothesis which Dr. Digby advanced in THE LANCET of Jan 20th, 1912. Since then I have made several other contributions on this subject.[3] It is gratifying to me to find my views so well supported by a pathologist of Dr. Digby's ability. For with him I feel that this important physiological subject has been allowed to slip into the background. The only real progress that can be said to have been made since Metchnikoff's discovery of phagocytosis in 1877 was that by his pupil Armand Ruffer.[4] Phagocytosis was realised by him to be merely one link in the chain of the process of the reactive mechanism of bodily defence. It was he who brought out the further important fact that the phagocytes not only came to the surface *from* the lymphoid or lymphatic gland that was concerned, but that after performing phagocytosis they re-entered the tissues without damage to them, making for the radicles of the lymphatic duct *in situ*, along and external to which he found them in great numbers. This observation was confirmed by certain other [illegible] only noticeable through the skin; it was not possible to observe it through the mucous membranes—in which situation it may safely be assumed to be a more common occurrence.

Dr. Digby uses the expression "subepithelial lymphatic glands"; unless a ranula may be said to be such, I have never heard of one before. To confound the solitary or the aggregate lymphoid gland with the lymphatic gland, which is, as a rule, seen to be remote from the epithelial surface to which it is physiologically related, is, in my humble opinion, a serious matter. It is true that the lymphoid and lymphatic systems of glands are so closely related it is difficult to discuss them apart. But they are, in fact, quite apart physiologically and anatomically. This I am hoping to show in a paper on which I am at present engaged. As the author in his former paper doubts the existence of lymphoid glands in the skin, owing to its greater keratinous protection, I beg to point out that the modified lymphoid glands of the skin are "the large prickle cells" of Malpighi. These are those that hypertrophy when they come into function in vaccination for variola; they form the sides of the umbilication. Similar evidences of their function are to be met with in a host of *exogenous* skin infections.

One more point and I have done. When the author says, "Solitary bacteria and cells loaded with bacteria can also be seen in their passage through the epithelium," he seems to imply that the bacteria possess powers of penetration as much as the phagocytes This I have endeavoured to show cannot possibly be the case with non-flagellates. Ruffer himself drew attention to the fact that bacteria found under the mucous surface must have been "phagocyted" to be conveyed thither; that they could not otherwise penetrate the undamaged surface either by their motility, if any, or by chemiotaxis. Chemiotaxis would seem to be more a function of the phagocyte than of bacteria in such situations.

I am, Sir, yours faithfully,

Harley-street, W., June 21st, 1913. H. D. MCCULLOCH.

[6] THE LANCET, May 17th, 1913.

THE LATE DR. RODERICK MACLAREN.

To the Editor of THE LANCET.

SIR,—Dr. Roderick Maclaren, of Carlisle, who died last week, possessed the rare combination of a gentle, almost shy, and retiring disposition with a strong personality. His keen, shrewd knowledge of the world, coupled with a profound acquai[illegible] surgery, and [illegible] the large con[illegible] 30 years sinc[illegible] never ceased [illegible] relationship gave. No one who knew Maclaren could fail to love and respect him, and most of his assistants developed into life-long friends. There are many men now practising medicine who remember a kind and generous friend, one whose standard of living has influenced their whole life. Intuitively he always seemed to know what ought to be done, and he did it regardless of the consequences.

He was a man of action; he thought deeply, reasoned clearly, and always acted with decision and firmness. Expediency had no place in his vocabulary.

Young men who are entering on medical practice have many lessons to learn during their first assistancy, and yet under Maclaren how gently but emphatically were these lessons taught. One example will suffice, and although it occurred nearly 30 years ago, it left an indelible impression on my mind. A young married woman who had secondary syphilis was acutely ill, and it was apparent that she might die at any moment; she was nine months' pregnant, and it might therefore be my duty, in my chief's absence, to attend her if she were *in extremis* I must have said something which showed that I was prepared to neglect what Maclaren thought would be my obvious duty, for I well remember his genuine astonishment that I should for one moment hesitate in the event of her death [illegible] Cæsarean section. The fact [illegible] have difficulty in performing [illegible] calculations. The unborn child had to be saved, and that was all Maclaren thought about.

Many have lost a true friend; all will feel that his life was an ennobling inspiration. He has left an enduring example, and those who knew him best and loved him feel how true it is that "to live in the hearts of those we leave behind is not to die."

I am, Sir, yours faithfully,

JOHN COLLIE.

Porchester-terrace, Hyde Park, W, June 23rd, 1913.

ANOMALIES OF THE LUNACY LAW.

To the Editor of THE LANCET.

SIR,—We appreciate your notice of our reprint on Lunacy Law. At the same time we think one passage in your annotation last week bearing this title calls for comment from us. We refer to your criticism of our choice of lawyers in place of specially appointed justices in regard to reception orders and other judicial matters. You suggest medical men. Our reason for suggesting lawyers was (and *is*) the fact that already two medical men are parties to reception orders. As the duties of the specially appointed justices are legal ones, and not medical, we feel that a lawyer is better equipped to undertake such functions as we suggest than a medical practitioner.

We recognise, however, the value of your criticism, particularly in regard to the present system that practically allows

St. George's Hospital exceeds, I believe, £5000, whereas the sum which has caused the discussion with the King's Fund is very much smaller. ANOMALIES OF THE LUNACY LAW.

To the Editor of THE LANCET.

SIR,—We appreciate your notice of our reprint on Lunacy Law. At the same time we think one passage in your annotation last week bearing this title calls for comment from us. We refer to your criticism of our choice of lawyers in place of specially appointed justices in regard to reception orders and other judicial matters. You suggest medical men. Our reason for suggesting lawyers was (and *is*) the fact that already two medical men are parties to reception orders. As the duties of the specially appointed justices are legal ones, and not medical, we feel that a lawyer is better equipped to undertake such functions as we suggest than a medical practitioner.

We recognise, however, the value of your criticism, particularly in regard to the present system that practically allows mediocrity,' but that their work renders it essential that they should be good general practitioners His very excellent article makes it unnecessary to advance further arguments for the appointment of consultants but he does not consider certain of the difficulties

The advantage of having at call a highly trained surgeon will be admitted by every medical superintendent The latter must always be the first court of appeal for his assistants in any doubtful case, and if he can refer the problem to one of a group of specialists he will find his position easier But this affords another opportunity for that shifting of responsibility which is the curse of Poor law work In an emergency the nurse at once summons the medical officer of the ward, he will submit the matter to the medical superintendent If it be an administrative question the latter will refer it to his special committee, if it be a professional one he will lay it before the consultant if there be one To recognise one's limitations is a priceless gift, but its possession invites the risk of shirking Certain infirmaries already possess a consulting surgeon and it of the l law system— has b it rec ly appointed the idea of appointing a spitals is absurd Nowhere in the world apart from themselves could there be found such a matured knowledge of the infectious fevers as the medical superintendents of the Asylums Board's institutions have acquired

Again many skilled surgeons reside in Poor law infirmaries and it is not an unheard of event for the assistant medical officers to work at some special hospital as clinical assistants Another point is this a visiting physician enjoys the opportunity of testing new therapeutic discoveries and here is a chance for the clashing of wills when the medical superintend the cry of 'experimenting his committee or by some ct is not mentioned by the contributor to the *Morning Post* who speaks rather of the development of science No development is possible when the most ordinary technique of clinical pathology is condemned by laymen as conducting experiments on those who are unable to leave the institution There is further, the consider f an honorary staff would of appointment by the ass could no longer do independent work, but would have to refer all things to the visiting man as they did in their raw youth The man who takes an infirmary appointment without having performed the severe but priceless drudgery of a residentship in a general hospital is fortunately uncommon but the others who have undergone this training are not likely to be gratified at the prospect of continuing it indefinitely

For certain reasons the proposed reform would be welcome but it will have to be devised with punctilious care and due foresight of its possible drawbacks

WORKMEN'S COMPENSATION ACT A QUESTION

To the Editor of THE LANCET

SIR,—I should like your views on the following subject I am surgeon to a small general hospital which is entirely provided and paid for by the employees of one of our large industrial concerns During the course of the year I am called upon to do a number of radical cures for hernia These men nearly always receive "compensation and if the case does go to court they generally win the day This morning I was asked by the "compensation department of the employers to allow their "compensation surgeon to be present at my hernia operations I refused as I consider such a position to be untenable if to be pursued as a custom in even a voluntary institution but much more untenable in a private hospital Moreover the proposal smacks somewhat offensively of a lack of confidence in my good faith both in the operating theatre and in the witness box Not only do I object on the grounds mentioned above but I further object on the ground of the possibility of an academic discussion arising in the theatre over an unconscious patient with its inevitable accompanying interruption and delay There is no parallel between a post mortem examination and an operation as the employers would like to imply, and I know of no hospital where such a course is pursued in the operating theatre

June 23rd 1913 *LISBON*

*** Our correspondent is perfectly right in the position which he has taken up —ED L

IRELAND

(FROM OUR OWN CORRESPONDENTS)

The Dublin Insurance Committee

IT is not only the medical profession of Dublin who object to the recent action of the Insurance Commissioners in appointing "medical advisers for Dublin and the adjacent urban districts The Dublin County Borough Insurance Committee at its meeting on June 19th decided by a large majority that, if applicants for sanatorium benefit were to be compelled to secure certificates from one of the 'medical advisers as it had been notified by the Commissioners would be the case the committee would decline to administer the benefit Hitherto the Insurance Committee has received preliminary reports from the applicant's own medical attendant and has paid a fee of 5s for each report and it does not appear that the Commissioners have power to dictate to the committee as to the manner in which it is to administer the benefit

The Conjoint Committee

At a meeting of the Conjoint Committee held last week arrangements were made for the holding of a delegates meeting representative of the profession in July Resolutions were passed by the Conjoint Committee regretting the action of the Commissioners in appointing 'medical advisers' in the county boroughs of Dublin Waterford and Limerick and in threatening to adopt similar measures in other areas and condemning their action as a Government department in offering preferential treatment as an inducement to medical men to join the panels contrary to the expressed decision of the profession in their areas The action of the Commissioners was stigmatised as intimidatory and in view of the altered circumstances the committee suggest that the local Medical Committees should reconsider their action in advising their members to go on the panel for certification They also call upon the universities colleges and hospitals to use their influence in preventing recently qualified -ments under the e wishes of the

The Irish Medical Association and the Insurance Commissioners

The council of the Irish Medical Association at a meeting on June 19th passed resolutions to the effect that they refused to work the sanatorium part of the Insurance Act, because of the action of the Insurance Commissioners in appointing medical men for certification for purpose of sickness and sanatorium benefits in opposition to the wishes of the Irish Medical Association

The Increase of Work under the National Insurance Act

At the Coleraine board of guardians on June 21st Dr T J Creery, dispensary medical officer for Coleraine applied for assistance for two months owing to the fact that the dispensary attendance had increased by more than a third during the past six months The clerk stated that the patients now as before the Insurance Act could avail themselves of the medical benefits under the Poor law system of dispensary aid, but insured persons now sent for the doctor on the least illness to get a sickness benefit certificate and the doctor was required to be in constant attendance on each case until the patient resumed work His only remuneration for the extra work thus entailed was the 1s 3*d* per head for certification for each person on his panel It was decided by the casting vote of the chairman to appoint for two months an assistant at a salary of two guineas weekly

Belfast Hospitals

On Saturday June 14th there was a street collection in Belfast on behalf of the funds of the Royal Victoria Hospital, when upwards of £900 were collected, and it is mediocrity,' but that their work renders it essential that they should be good general practitioners His very excellent article makes it unnecessary to advance further arguments for the appointment of consultants but he does not consider certain of the difficulties

The advantage of having at call a highly trained surgeon will be admitted by every medical superintendent The latter must always be the first court of appeal for his assistants in any doubtful case, and if he can refer the problem to one of a group of specialists he will find his position easier But this affords another opportunity for that shifting of responsibility which is the curse of Poor law work In an emergency the nurse at once summons the medical officer of the ward, he will submit the matter to the medical superintendent If it be an administrative question the latter will refer it to his special committee, if it be a professional one he will lay it before the consultant if there be one To recognise one's limitations is a priceless gift, but its possession invites the risk of shirking Certain infirmaries already possess a consulting surgeon and it [illegible] of the I[illegible] law system— [illegible] has but rec[illegible]ly appointed [illegible] the idea of appointing a [illegible]spitals is absurd Nowhere in the world apart from themselves could there be found such a matured knowledge of the infectious fevers as the medical superintendents of the Asylums Board's institutions have acquired

Again many skilled surgeons reside in Poor law infirmaries and it is not an unheard of event for the assistant medical officers to work at some special hospital as clinical assistants Another point is this a visiting physician enjoys the opportunity of testing new therapeutic discoveries and here is a chance for the clashing of wills when the medical superintend[illegible] the cry of 'experimenting [illegible] his committee or by some [illegible]ct is not mentioned by the contributor to the *Morning Post* who speaks rather of the development of science No development is possible when the most ordinary technique of clinical pathology is condemned by laymen as conducting experiments on those who are unable to leave the institution There is further, the considerat[illegible] f an honorary staff would [illegible] of appointment by the ass[illegible] could no longer do independent work, but would have to refer all things to the visiting man as they did in their raw youth The man who takes an infirmary appointment without having performed the severe but priceless drudgery of a residentship in a general hospital is fortunately uncommon but the others who have undergone this training are not likely to be gratified at the prospect of continuing it indefinitely

For certain reasons the proposed reform would be welcome but it will have to be devised with punctilious care and due foresight of its possible drawbacks

I am, Sir, yours faithfully,

WORKMEN'S COMPENSATION ACT A QUESTION

To the Editor of THE LANCET

SIR,—I should like your views on the following subject I am surgeon to a small general hospital which is entirely provided and paid for by the employees of one of our large industrial concerns During the course of the year I am called upon to do a number of radical cures for hernia These men nearly always receive "compensation and if the case does go to court they generally win the day This morning I was asked by the "compensation department of the employers to allow their "compensation surgeon to be present at my hernia operations I refused as I consider such a position to be untenable if to be pursued as a custom in even a voluntary institution but much more untenable in a private hospital Moreover the proposal smacks somewhat offensively of a lack of confidence in my good faith both in the operating theatre and in the witness box Not only do I object on the grounds mentioned above but I further object on the ground of the possibility of an academic discuss on arising in the theatre over an unconscious patient with its inevitable accompanying interruption and delay There is no parallel between a post mortem examination and an operation as the employers would like to imply, and I know of no hospital where such a course is pursued in the operating theatre

I am, Sir, yours faithfully,

June 23rd 1913 *LISBON*

*** Our correspondent is perfectly right in the position which he has taken up —ED L

IRELAND

(FROM OUR OWN CORRESPONDENTS)

The Dublin Insurance Committee

IT is not only the medical profession of Dublin who object to the recent action of the Insurance Commissioners in appointing "medical advisers for Dublin and the adjacent urban districts The Dublin County Borough Insurance Committee at its meeting on June 19th decided by a large majority that, if applicants for sanatorium benefit were to be compelled to secure certificates from one of the 'medical advisers as it had been notified by the Commissioners would be the case the committee would decline to administer the benefit Hitherto the Insurance Committee has received preliminary reports from the applicant's own medical attendant and has paid a fee of 5*s* for each report and it does not appear that the Commissioners have power to dictate to the committee as to the manner in which it is to administer the benefit

The Conjoint Committee

At a meeting of the Conjoint Committee held last week arrangements were made for the holding of a delegates meeting representative of the profession in July Resolutions were passed by the Conjoint Committee regretting the action of the Commissioners in appointing 'medical advisers' in the county boroughs of Dublin Waterford and Limerick and in threatening to adopt similar measures in other areas and condemning their action as a Government department in offering preferential treatment as an inducement to medical men to join the panels contrary to the expressed decision of the profession in their areas The action of the Commissioners was stigmatised as intimidatory and in view of the altered circumstances the committee suggest that the local Medical Committees should reconsider their action in advising their members to go on the panel for certification They also call upon the universities colleges and hospitals to use their influence in preventing recently qualified [illegible] ments under the [illegible] e wishes of the [illegible]

The Irish Medical Association and the Insurance Commissioners

The council of the Irish Medical Association at a meeting on June 19th passed resolutions to the effect that they refused to work the sanatorium part of the Insurance Act, because of the action of the Insurance Commissioners in appointing medical men for certification for purpose of sickness and sanatorium benefits in opposition to the wishes of the Irish Medical Association

The Increase of Work under the National Insurance Act

At the Coleraine board of guardians on June 21st Dr T J Creery, dispensary medical officer for Coleraine applied for assistance for two months owing to the fact that the dispensary attendance had increased by more than a third during the past six months The clerk stated that the patients now as before the Insurance Act could avail themselves of the medical benefits under the Poor law system of dispensary aid, but insured persons now sent for the doctor on the least illness to get a sickness benefit certificate and the doctor was required to be in constant attendance on each case until the patient resumed work His only remuneration for the extra work thus entailed was the 1*s* 3*d* per head for certification for each person on his panel It was decided by the casting vote of the chairman to appoint for two months an assistant at a salary of two guineas weekly

Belfast Hospitals

On Saturday June 14th there was a street collection in Belfast on behalf of the funds of the Royal Victoria Hospital, when upwards of £900 were collected, and it is universities, 17 to training schools for midwives, 5 to municipalities, and 10 to benevolent institutions. In those hospitals 33,990 births took place, with 4487 operations; among the patients operated on there were 188 deaths. Puerperal fever occurred in 135 cases, with 61 deaths. Of the children born in the hospitals 1854 were stillborn, whilst 1104 died afterwards during the stay of the mother in the hospital, and there were 1433 cases of premature birth. The number of special ophthalmic hospitals with at least 10 beds was 96, of which 10 belonged to universities, 3 to provincial corporations, 3 to municipalities, 5 to benevolent societies, and 52 to private individuals. The total number of patients was 33,307, who stayed in the hospitals for 742,257 days in all, so that the average residence of a patient in hospital was 22·3 days.

The Protection of Infants.

The committee for the protection of infants in Prussia held a meeting recently, Dr. von Behr-Pinnow being in the chair. The meeting was attended by representatives of the Government and by numerous medical men, teachers, clergymen, and members of women's societies. The chairman stated that the vital statistics for the year 1911 were rather unfavourable, the increase of the population being 100,000 less than the average. One-third of this might be attributed to the decrease of births, one-third to general mortality, and one-third to infant mortality. This could have been avoided if all the scientific preventive methods had been used, as was shown by the fact that in localities where there was a well-organised system for the protection of infants the mortality had not increased. The year 1912 showed a remarkable improvement, as both the general mortality and the infant mortality were lower than they had ever been. Dr. Rott, of Berlin, gave a report on the subject of granting assistance to mothers nursing their infants. Such has existed in France since the beginning of the nineteenth century, and in the city of Augsburg in Germany for some 50 years, but a systematic organisation of this kind throughout Germany only began in the year 1905, wher [illegible] r. Oppenheimer. The [illegible] stem have led to its es [illegible] aid being given to the suckling mothers either in money or in food. In the majority of cases a litre of milk was given daily free of charge for a quarter of a year. In five cities rooms were provided in factories where the mothers working in the factory might suckle their infants. The expenses for that support of the mothers were rather considerable, being 180,000 marks (£9000) for the city of Berlin, and the funds collected for the purpose were constantly increasing. Dr. Paul, a town councillor of Magdeburg, said that in that city mothers were supported from the fifth until the fifteenth week after the birth of their infants in winter, but that the support was given in summer immediately after birth, and continued until the sixth month. Unmarried mothers and married mothers whose husbands earned less than 1050 marks (£52 10*s.*) per annum were entitled to be assisted, on condition that they nursed their children themselves and came regularly at the appointed time to have their infants examined in the municipal dispensary. Dr. Thiemich, of Magdeburg, said that assistance was given to mothers either as an incentive to them to avoid too early weaning of the infant in cases where the social condition of the mother would allow the continuation of suckling; or, on the other hand, it was given as a support to very poor mothers intending to wean their children for financial reasons. Dr. Freund, of Breslau, said that not much was done for children after the infant age until the time when they began going to school. The mortality among infants was considerable, but during the next few years of life it was rather small. Tuberculosis and rickets were especially common, the causes being not only bad housing conditions and insufficient food but also a want of knowledge on the part of the mothers of the proper methods of bringing up children. Homes for weak, backward, and invalid children were a necessity. Dr. Gottstein, chief medical officer of the city of Charlottenburg, said that the care of children from infancy until the school age should be under the control of the same medical officer until they came under the care of the medical officer of the schools, and would thus be under continuous supervision. The organisation for the care of young children should be in connexion with dispensaries for tuberculosis, dental clinics, &c. In this way a history of the health of every child could be prepared and given to the medical officer of the school so that he might have some information as to the condition of health of each child.

Calcareous Deposits under the Skin.

An interesting case of calcareous deposit under the skin was shown by Dr. Gontermann, of Spandau, at a recent meeting of the Berlin Medical Society. There was no history of gout in either the patient or her family; the first symptom developed when she had been cutting bread with a knife for about half an hour, so that there had been much pressure exerted on the region of the fourth metacarpo-phalangeal joint. At that spot a bunion formed under which a nodule developed, and this in course of time became enlarged without being painful. Two years later, however, a number of new nodules of different sizes developed, all lying free in the subcutaneous tissue. By an exploratory incision it was found that they had a very smooth capsule and were nowhere adherent to the skin, and by radiography it was ascertained on different occasions that they had grown in the direction of the ramification of the vessels. Professor Hansemann, who had examined one of the growths, found that it consisted of amorphous carbonate of lime with a small quantity of phosphate of lime. The etiology was rather obscure; the pressure of the handle of the knife on the patient's hand was certainly the cause of the first deposit. After sustaining this injury she contracted syphilis, and Professor Hansemann suggested that this circumstance might have contributed to the further development of new growths. Such cases are very rare, as only four have hitherto been described in medical literature.

Performance of a Stage Play in the Interest of Public Health.

At the instance of the German Society for the Prevention of Sexual Diseases, the drama "Les Avariés," by the French author, M. Brieux, has been represented in a German translation in the "Deutsche Theater," which belongs to Herr Reinhardt, the producer of the "Miracle." The drama is based on the sad story of a man who became syphilitic, and it shows the sequelæ of syphilis in wedlock. It is designed to give the public a clear insight into the matter in a more efficacious way than is possible by lectures and pamphlets. The first performance took place on June 23rd.

June 24th.

THE CORONERS' SOCIETY OF ENGLAND AND WALES.—The annual banquet of this society was held on June 19th at the Holborn Restaurant, London, under the chairmanship of Mr. T. E. Sampson, J.P., coroner for Liverpool and president for the ensuing year. The toast of "The Law and Medicine" was proposed in an amusing speech by Dr. R. W. Gibson, who touched on the debt which the community owed to both professions. The reply was entrusted to Mr. C. L. Samson, president of the Incorporated Law Society, and to Dr. W. H. Willcox, senior scientific analyst to the Home Office. Dr. Willcox in his speech paid a tribute to the work done by coroners and expressed the opinion that in the coroners' courts medical evidence was heard at its best. The toast of the "Coroners' Society" was submitted by Mr. Branfield, president of the Liverpool Law Society, who spoke in terms of warm appreciation of the chairman and indicated the pleasure with which his fellow citizens had learnt of the honour conferred upon him by the society. The President, in reply, dwelt on the importance of the coroner's office and the opportunities which it offered for the expression of sympathy with those in affliction. Dr. F. J. Waldo, Vice-President, proposed the health of "The Visitors," and in welcoming the various official guests of the society referred briefly to the prospects of improvement in the existing coroners' law. Sir William Byrne, Assistant Under Secretary to the Home Office, and Mr. Percy Simmons, L.C.C., responded on behalf of the guests, and each dwelt on the pressing need for legislation giving effect to the findings of the Departmental Committee on Coroners' Inquests. The concluding toast, that of "The Officers of the Society," was very heartily received. Between the speeches an enjoyable musical programme was carried out under the direction of Mr. Arthur Winter. To the honorary secretary of the society, Mr. Walter Schröder, congratulations are due on the success of the evening.

universities, 17 to training schools for midwives, 5 to municipalities, and 10 to benevolent institutions. In those hospitals 33,990 births took place, with 4487 operations; among the patients operated on there were 188 deaths. Puerperal fever occurred in 135 cases, with 61 deaths. EDITORIAL NOTICES.

nost important that communications relating to the l business of THE LANCET should be addressed *ly* "TO THE EDITOR," and not in any case to any who may be supposed to be connected with the l Staff. It is urgently necessary that attention should to this notice.

ecially requested that early intelligence of local events g a medical interest, or which it is desirable to bring r the notice of the profession, may be sent direct to office.

original articles, and reports should be written on side of the paper only, AND WHEN ACCOMPANIED LOCKS IT IS REQUESTED THAT THE NAME OF THE AND IF POSSIBLE OF THE ARTICLE, SHOULD WRITTEN ON THE BLOCKS TO FACILITATE IDENTI-TION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE *LANCET Offices*, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.
